The lectures comprised in these volumes were delivered originally to small classes of students who represented two distinct types; (1) young farmers and the sons of farmers familiar with ordinary farm practice, but desirous of acquiring some knowledge of the sciences upon which the art of agriculture rests, and (2) city-bred men, often graduates of the academic department of the University, who intended to establish themselves upon farms, or to occupy country-seats, or to become landscape gardeners. The lectures, therefore, were not prepared for advanced students in chemistry, and the most abstruse of them are easily within the comprehension of one who has a fair elementary knowledge of that science. This does not imply that the more profound problems in agricultural chemistry are ignored, for these are clearly and exactly stated, and the results of the most recent and trustworthy investigation, both in Europe and America, are set forth with ample detail. Indeed, we know of no other work in which those fundamental problems of chemical science, upon which the practice of agriculture is based, are more skillfully grouped and presented. And this fact makes it the most instructive and helpful manual that has appeared in this country since the publication of Professor Johnson's "*How Crops Grow*" and "*How Crops Feed*." Naturally enough the subject of fertilizers with their modes of action upon various soils and crops occupies large space, but this does not exclude the careful treatment of such subjects as Tillage, its Purposes and Processes; The Movements of Water in the Soil; The Atmosphere as a Source of Plant Food, and The General Relations of the Plant to Soil and Air. This means not only that the lectures are of interest to farmers and gardeners, but to all persons who are attracted by the mysteries of vegetable life which are constantly going on about them.

There are few forehanded farmers who do not read some agricultural paper, and the teachings of the best of these journals are usually abreast of the advance in scientific discovery. But in addition to these indispensable aids we can think of no

better book to keep lying within easy reach than this one of Professor Storer's. Every day the thoughtful farmer is confronted by difficult problems in actual practice, and for nearly every one of these will be found a reference in the very complete index to these volumes. The book has, to our knowledge, proved of signal service in just such cases as a manual of daily practice. It would be a great advantage to every country home if its owner would place himself in just such relations to this book. If the true requirements of plant-growth were better understood we should see fewer hungry lawns, and spindling trees, and sickly shrubberies, and famished gardens generally. Some of the students to whom these lectures were delivered were in course of training for the profession of landscape gardeners, and knowledge like that imparted here should be an essential portion of the equipment of every artist of this kind. This knowledge, however, should not be confined to landscape gardeners or to those who till their acres for profit only. Country life loses half its charm to those who take no inquisitive interest in the processes and conditions of plant-life and development. The owner of a country-place who cannot give intelligent directions on methods of enriching his land with plant food and making that food available, or on the best mechanical preparation of his soil for a given purpose, or on the kind of cultivation best adapted to special cases, may derive some pleasure from his possession, as may the owner of a yacht who has no skill to sail her. But the keenest delight in a rural home only comes from an intimate acquaintance with the soil itself and an intelligent appreciation of its possibilities of production. To such a one the lawn, the pasture, and even the kitchen garden, offer fields for experiment and study that are ever fresh, and a new interest is added to every plant that grows for ornament or use. No safer guide in the wholesome studies above alluded to can be found than this manual, so that it can be commended not only to thoughtful farmers, but to all others who find recreation of mind and body in the abounding vegetable life of the fields and in searching for the laws under which this life is ordered.

Periodical Literature.

In the May number of *The Portfolio* is given the first installment of a long description of Charlecote Hall in Warwickshire, the courtyard of which was pictured in GARDEN AND FOREST a few weeks ago. The text is partly architectural, partly historical in character, and the illustrations are numerous and pretty. The largest among them will especially interest our readers, as it gives the reverse of the view with which they are already familiar, showing the house from the terrace-walk beyond the courtyard wall. The second installment of the article does not appear in the June number of the magazine, but will doubtless not long be delayed; and in it we hope to find a description of the park which Shakespearian legend has made so famous.

In *Good Words* for June Mr. Grant Allen writes a pleasant chapter on "The Breadstuff of the Desert." His subject is of course the Date Palm, and in a lively and popular way he gives much information with regard to its manner of growth and the multifarious uses to which it is put. As he explains, this tree does much more than furnish the Arab of the desert with his chief—almost his only—article of food. "He eats it," says Mr. Allen, "he drinks from it, he lives under it, he burns it, he buys with it whatever he needs from other regions. It is his all, his estate, his heritage, his banker." Fortunately for him it grows best where no other tree will thrive; and by one of nature's seemingly deliberate economies, it ceases to grow well where other trees begin to flourish. The article is accompanied by a number of illustrations, but no one of them reveals the full beauty of the Date Palm as it stands in the memory of all who have been fortunate enough to see it in its African home—at once majestic and lovely, noble in its simplicity of form, yet consummately graceful in the way it yields in varying degree to the varying touches of the wind. A northern tree which is sturdy enough to be called, under any conditions, stately and majestic, always keeps its sturdy air, preserving an almost unyielding trunk even in the strongest wind. But the trunk of the Palm is superbly dignified in its apparent rigidity when a light wind tosses its feathery crown, yet bends deeply to a stronger wind, gaining grace for the moment by some sacrifice of majesty. It is this constant change in air and expression, this alternation of the effect of strength with the effect of pliancy, this look as of now dominating the elements and now being dominated by them, which makes the Palm so attractive to the traveler's eye and does so much to compensate it for the fact that it finds no other tree in the wide, level landscape.

Notes.

Prices of cut flowers are so unsteady at this season, that our weekly reports of the Retail Flower Market will be discontinued until the Fall trade begins.

The place for holding the August meeting of the Society of American Florists has again been changed. The society will meet in the Cooper Union and the exhibition will be in Nilsson Hall.

The florists and gardeners of Boston and vicinity have planned for a holiday on July 24th. It will take the form of an excursion down the harbor on a steamer, with a short landing on one of the islands. The affair will be under the auspices of the Gardeners' and Florists' Club.

It appears from a recent issue of the *Revue de la Horticulture Belge* that the flowers of the Locust (*Robinia Pseudacacia*) are considered a delicacy for the table in Europe, being served in *pâtés*. The flavor is pronounced delicious. The flowers of the European Elder (*Sambucus nigra*) are sometimes used in the same way.

A convention of the Cranberry-growers of Cape Cod will be held in the town of Sandwich during the present month for the purpose of discussing the necessities of this already important and rapidly developing industry, and especially to devise methods for the more general introduction of the Cranberry crop into European markets.

It is gratifying to note the constantly increasing use of the Gloxinia as a florists' flower. It has been adopted generally by the florists of Boston as a standard variety in their summer stock. Its rich coloring and graceful form recommend it for use in floral designs for all occasions. It is very easily bruised, but if handled carefully will keep for a long time.

Good blue flowers which can be used for cutting purposes are never abundant, but more blue is now seen in the windows of Philadelphia florists than usual, because the beautiful *Delphinium formosum* is now at its best and a prime favorite. A few of these Larkspur sprays with any yellow flower, especially with Roses like *Perle des Jardins*, *Maréchal Neil* and *Sunset*, or a sprig of it in a cluster of *Aquilegia chrysantha*, produces a most charming effect.

Professor Asa Gray left by will the copyrights of all his books to the President and Fellows of Harvard College, for the benefit of the Gray Herbarium, on condition that proper provisions be made for their renewal and extension by new editions, continuations and supplements as might be necessary to increase and prolong the value of the bequest. His herbarium, unequalled in North American plants, and library, he presented to the college many years before his death.

In the collection of Orchids in the recent exhibition in Paris, which won for Sander, of St. Albans, the *Grand Prix d'Honneur* offered by the President of the Republic, was a noble specimen of *Cattleya guttata Leopoldi*, more than four feet high by as much across, and bearing more than a hundred flower-stems, splendid great specimens of *Lalia purpurata*, and innumerable forms of *Odontoglossum crispum*, *O. vexillarium*, *O. Harryanum*, and of *Cattleya Mossiae* and *C. Mendeli*.

All the plants remaining on the estate of the late C. M. Hovey, at Cambridge, Mass., were sold at auction on Monday, July 9th. Many of these plants were seedlings, and rare specimens collected by Mr. Hovey during nearly half a century, and with which he never could be induced to part. The sale attracted many buyers, mainly florists, from all parts of New England, and prices realized were good, considering the condition of the stock, of which the greater part gave evidence of sad neglect.

The Promenade along the shore of East River Park, in this city, will be a useful and attractive feature of that work. It will be twenty-seven feet wide, and but a few feet above the mean water-level, so that the cooling influence of the tides, which always flow swiftly at this point, will be most grateful in summer weather. When the walk is extended along the entire shore, including the newly acquired addition to this Park, it will be large enough to accommodate great numbers of visitors from a district which will soon be densely populated.

A common European Hawkweed (*Hieracium aurantiacum*) is now pretty thoroughly naturalized in some places in the Eastern States and is likely to become a troublesome weed here. In Greene County, in this State, it has already taken

almost complete possession of some fields, and as this plant spreads from stoloniferous, underground stems, it will probably spread as fast and be as difficult to eradicate as the White Weed or Daisy. It is a hairy plant, with a cluster of narrow leaves near the ground and a simple naked scape a foot or more high, bearing a head of deep orange-colored or flame-colored flowers.

In commercial horticulture all good flowers are scarce, especially white ones. This is partly due to the hot week in late June and partly to the fact that this is "between seasons" for those who grow flowers for the wholesale market. That is, the Rose plants, for example, which did service last winter and spring, are now thrown out, and younger plants and new soil are introduced, and the success or failure of the supply next winter is often determined by the treatment of the stock at this critical period. Sickly plants, badly prepared soil, a lack of watchfulness now, mean a scant crop of inferior flowers next season.

A prominent nurseryman stated, recently that the reduction of freight-rates on nursery stock brought about by the efforts of the committee appointed by the American Association last year would save to customers and the trade \$50,000 during the present season. The reduction applies only to stock packed in boxes and thus puts a premium on proper packing. Such stock is now carried as third-class freight, instead of first-class, as it was formerly rated. Some of the arguments used to secure this concession were that boxed stock can be roughly handled without injury; that when transported with ordinary dispatch it is in no risk of damage, and that the carrying of nursery stock brings in time more freight in the shape of fruit.

M. Beurdeley, in a report made recently to the Horticultural Society of France, invites the attention of horticulturists to the results of his experiments with male and female plants of Asparagus. He finds the former the more productive, seventy-six shoots having been produced by twelve crowns of the female plant, or an average of nearly six and one-half shoots for each crown, while twenty crowns of the male plant yielded 244 shoots, or an average of over twelve shoots from each crown. The experiments were only carried on during a single year, but this is a subject of such practical importance to gardeners, that, as the *Revue Horticole*, from which this information is derived, suggests, they should be continued on a larger scale and during a period of several years.

A correspondent of the journal published by the *Société des Agriculteurs* in Paris sends some interesting information with regard to the very large trade done in Cauliflowers from Roscoff and other places in Lower Brittany. He says that every day, for a period of about two months, seventeen or eighteen trucks, each holding about four tons of Cauliflowers, are dispatched from four or five stations, thus making a total of over 4,000 tons of Cauliflowers during the two months. About a thousand plants go to the ton, and the average price is \$17.00 per ton, or something under \$70,000 for the whole lot. The bulk of them are shipped at Nantes for Bordeaux and the southern markets, or at Cherbourg and Havre for England, though a great many trucks go to Paris. An enormous profit in this trade is made by the middlemen, and the correspondent not unreasonably asks whether, with a little management, a large proportion of this might not be secured by the growers themselves.

At the Cincinnati Exposition the American Forestry Congress exhibits a section of a Tulip tree with a chronological table of its history, showing that the tree began its life when Queen Elizabeth came to the throne in 1558, was a stout sapling when Saint Augustine was founded, and gave respectable shade when the Pilgrim Fathers landed in New England. When La Salle saw it on the banks of the Mississippi in 1682 it had become a tree of royal stature; when the United States began to exist as an independent nation it was four feet in diameter and when cut for the Cincinnati Exposition it had added another foot to its diameter, being five feet in 330 years. The Forestry Congress also exhibits a chart with many instructive illustrations of the present condition of our forest interests, both state and national. The Division of Forestry of the Department of Agriculture exhibits at the same place a collection of forest seeds; sections of 100 of our most important forest trees; 200 volumes on the subject of forestry in different languages, showing that there is such a literature; thirty-six heliotype pictures illustrating the effects of deforestation and the mode of reforestation in the French Alps, and a collection of tools used in European forest planting and management.

The Arid West and Irrigation.

THROUGHOUT the greater part of a region covering something like one-third of the total area of the United States, not including Alaska, the annual rainfall is so small that, except in spots here and there, the land is not arable unless artificially watered. This region has its western boundary at the Sierra Nevada, and, in some portions, at the Coast Range of the Pacific; it comprises the country from the northern to the southern frontier, including the great basin between the Sierras and the Rocky Mountains, the high plains to the eastward of the latter, and a large portion of western Texas. Until within a comparatively few years the most of this great expanse has been known only in the vaguest way and it was regarded as a hopeless desert, fit only for mining, or, in a limited way, for cattle ranges. To be sure, over a generation has passed since the Mormons turned the heart of this region into a rich garden, and for years Utah has possessed a population sufficient for statehood, so far as numbers are concerned. Utah has afforded a practical example of what might be accomplished throughout a large proportion of this region, much of which is even superior to the Salt Lake Valley in natural advantages of climate and water supply. But our people have been slow in applying the experiences of one locality to the requirements of another, and the Mormon lesson long went unheeded.

Now, however, this region is well penetrated by trans-continental railway lines and their branches, and its characteristics have become more widely known. The most of the lands of the national domain that are arable under natural conditions are now occupied; the crowding immigration has pressed its front ranks well forward into the arid belts, and called attention to the capabilities of the land there. The next chapter of the greatest migratory movement of modern times, the settlement of the American republic, will be the more complete occupation of the Pacific slope and the filling up of these great inland arid regions that recent investigations show to have been well inhabited by a sedentary aboriginal population. The development of the resources of a third part of our national

territory, suddenly found to be of great value instead of substantially worthless, is therefore a matter of vital importance and demands careful consideration as to the most efficient means of carrying it out. Even though but a fractional proportion of the entire area should prove fit for cultivation, it would still very considerably extend the immigration-sustaining capacity of our country, for history and prehistory both show us that irrigated lands sustain the densest of populations.

Although irrigation has accompanied the tilling of the ground from time immemorial, and probably, indeed, gave birth to agriculture, and therewith civilization itself, and while vast regions of our own continent were in pre-Columbian times made fertile thereby, still it has been comparatively unknown to the American husbandman until very lately. Now, however, its advantages are beginning to be perceived even beyond the confines of the arid districts. In the extensive market gardens about Boston, for instance, it is becoming universal, and in the east we may expect to see it applied with profit not only to many branches of horticulture, but the enormous augmentation of grass-growth which it produces will probably cause it to be introduced wherever practicable on the hay farms that constitute the chief agricultural interests in some of our Northern States, just as it has long been practiced for the same purpose in Germany and other portions of Europe under conditions of precipitation similar to ours.

Within the past few years irrigation has made enormous advances in all quarters of the great arid region of the west, and it is estimated that there are now over 14,000 miles of main canals, with over 200,000 miles of lateral, or supply ditches, representing an outlay of many millions of dollars, and bringing thousands of square miles under cultivation. Great enterprises have been carried out, and others are in execution, or have been conceived, in Colorado, Kansas, Montana, Idaho, Utah, California, New Mexico and Arizona, and the transformation in the aspect of extensive tracts in these states and territories has been magical. There is no better field for capitalists to-day, insuring large and certain profits, than in the carrying out of irrigating works in those parts of the United States. Unlike railways, the operating expense is slight. The development of the arid districts would undoubtedly be much more rapid were it not for the fact that the construction of canals, dams, etc., except where the natural opportunities are exceptionally easy to be availed of, requires an original outlay far beyond the reach of the average settler, and can only be effected either by the aid of capital, or through co-operative work, which is rarely practicable among settlers, except in the case of colonies, as illustrated by the admirable examples set by the Mormons in this respect.

The greater portion of the arid west is fortunately adapted, in its physical conformation, to the making arable, through irrigation, of a large and widely distributed proportion of its entire surface, consisting, as it does, of alternations of mountains and valleys. New Mexico and Arizona, particularly, are characterized by detached groups of mountains rising from broad valleys, forming great and uniformly sloping plains. These mountains cause precipitation and distribute the rainfall over the plains below, where it normally runs to waste in the great gullies it has worn in the land. Were it possible to store up all the rain that now flows away, every inch of these regions might be made productive. While that is impracticable, much more can be done in this way than is now hardly dreamed of. It is safe to assert that in all this region there is hardly a mountain chain or group where, in the neighboring plains, irrigation may not be practiced to a greater or less extent. It even seems by no means visionary to look for the day when, through various means available to modern ingenuity, the arid west will be made as proportionately productive as is the Atlantic slope, the dry uplands of the former utilized for

various desert products, such as fibrous plants and other growths now deemed worthless, and for sheep pasturage, etc., thus corresponding to the uses of the rocky hills and pastures that form a large proportion of the area of the latter section of our country. Valuable uses are constantly being found for land once worthless—as in the Cranberry bogs of Cape Cod and the great Henequen plantations of sun-parched Yucatan. Some time the day may come when it will be said: There is no desert! The encouragement of irrigation will hasten that day for our country.

Trees in Washington.

MR. PETER HENDERSON, in the last number of *Harper's Magazine*, describes the tree-planting which has been accomplished in the City of Washington during the last fifteen years. No less than 120 miles of streets, or 240 miles of trees, have been planted in that time; and in no other American city has street planting ever been attempted on anything like the same scale, or has produced results immediately so satisfactory. An examination, however, of the list of trees which have been planted, shows that the Commission who have controlled these plantations have been governed by the desire for immediate effect rather than for the permanent embellishment of the city. White Maples, for example, line fifty-five miles of streets, or nearly one-half of the distance planted; sixteen miles are planted with the Cottonwood, and ten miles with the Ash-leaved Maple or Box Elder. These are all excellent trees for the prairies of Nebraska or Kansas, where trees are needed that can grow rapidly in a dry soil, and where all other considerations are secondary to immediate results, but they are entirely out of place in a city of the architectural pretensions and of the climate of Washington. They are trees with brittle branches, and neither long-lived nor in any way suited to adorn the capital of a country like the United States, rich in trees unsurpassed in beauty and variety. Indeed, it would be difficult to select three deciduous trees in the forests of this country less fitted for this particular purpose. They are very easily and quickly raised; they are readily transplanted, and they grow with great rapidity. They soon become unshapely and unsatisfactory, however, and any city where the streets are planted with them will have a cheap appearance, whatever may be the character of its buildings. The number of fine trees which could be used to adorn appropriately the streets of Washington is considerable. The Tulip tree is perfectly at home in that climate. It is one of the noblest trees of the American forest. There are few more beautiful trees anywhere. The Commission have planted only 1,712 Tulip trees. Some of the American Oaks are admirable street trees, notably the Pin Oak, the Red Oak, the Willow Oak, the Scarlet Oak and the Shingle Oak. These all thrive in the neighborhood of Washington, and they are all trees which can be easily grown and transplanted. They grow rapidly, too, as does the Tulip tree, although less rapidly in youth than Cottonwoods and Soft Maples, but they go on increasing in beauty for a century, and might be expected to last in Washington for a much longer period even. The Commission have planted 273 Oaks all told, including some worthless European varieties. Only 832 Sugar Maples have been planted, although this is one of the best street trees in the United States, while ten miles of Norway Maples have been planted, in spite of the fact that it is in every way an inferior tree, and often disfigured in this country in summer by thrip. The White Poplar of Europe is one of the ugliest trees ever introduced into this country; 1,863 of these have been set along the Washington streets, or 600 more than the number of Honey Locusts used; yet the Honey Locust is an excellent street tree—in many respects one of the best which has ever been tried in this country for the purpose. The trees to which we have here called attention—and there are many others which might have

been selected in preference to those employed by the Commission—have all been successfully planted in towns in different parts of the country. In the town of Flushing, in this State, for example, where, perhaps, more than in any other in this country which we can now recall, there are lessons in street planting to be learned, both in regard to what trees to plant and what trees not to plant, there are rows of noble Tulip trees, and Pin Oaks, Willow Oaks and Lindens, which speak for themselves, and show how beautiful a well planted street can be made.

The trees planted in Washington have been badly selected, and the permanent results of these plantations cannot fail to be disappointing; the methods, however, of planting, of pruning and of protecting the trees adopted by the Commission, as described by Mr. Henderson, are admirable, and far ahead of anything which has been done in urban planting in this country. It is not surprising, therefore, that the immediate results obtained are so satisfactory.

IT now seems probable that the postage on seeds, cuttings, bulbs and roots will be reduced to at least eight cents a pound, which is half of the present rate, and the Postal Improvement Association, to whose efforts this reduction is largely due, still hope that the rate may be ultimately fixed at four cents, as it was made originally in the Senate Bill. By some oversight the words "plants and trees" were omitted in the bill, and it is to be hoped that it will be amended so as to include both of these, although, perhaps, the word "plants" would cover the entire case. It is a matter which should not fail for lack of definite language, and certainly there is no sound reason why plants should not share the advantages accorded to seeds and bulbs. If the Government can afford to carry one it can equally afford to carry the other. And there are special reasons why plants should have the preference. They are more perishable, and in places remote from express, the mails offer the only chance for speedy delivery. It has been urged by some nurserymen that a lower rate of postage would encourage the dissemination of undersized trees and thus injure the business. But with postage at one-half or one-fourth of the present rate, much larger trees could be sent for the same amount. To the argument that packages of small trees or shrubs are too bulky for convenience in the mails, it may be replied that we have seen mail packages of forest tree seedlings which occupied less space than the same weight of ordinary seeds or bulbs. In short, if cheap postage on seeds, bulbs and cuttings is a measure of public utility, a similar reduction on plants must prove even more beneficial to the people at large, and the Post-office Department can carry the latter with as little trouble and expense as it can carry the former.

We have reason to believe that the forest tree seedlings posted in one dollar packages by Robert Douglas & Sons have had a marked influence on forest planting. These seedlings are now growing in hundreds of places where not a tree would have been planted but for the opportunity thus afforded by the mails. We can think of no agency more effective in stimulating an intelligent and practical interest in forest planting than these cheap mail packages, and the enterprise deserves all possible encouragement.

If the reduction of postage on plants will enlarge this business in forest tree seedlings it will confer a benefit on the whole country, and certainly it would be a public wrong to neglect this interest while favoring others no more deserving, to say the least. If plants were overlooked by a mistake in framing the bill, there ought to be little difficulty in correcting it. If the word was left out advisedly and for the sake of crippling one branch of business in the interest of another, there is still more urgent reason why the people should demand its restoration, in the name of fair dealing, as well as for the general good.

The Gardens of the Alhambra.

IN our studies of landscape architecture we are so inclined by influence and tradition to turn to French, English or Italian examples for inspiration and guidance, that much of the work in other countries is lost sight of or neglected, although affording excellent opportunities for study. Spain, in particular, is almost unknown to the landscape architect of to-day; yet the work which the so-called barbarian Moors left behind them in that wonderful country is, in some respects, hardly excelled anywhere in the world. The Alhambra of Grenada is the best known and one of the most pleasing examples of the manner in which the Moors could treat a site with little natural promise. The city of Grenada is built in a ravine, following the course of the Darro, and spreading out into a plain at the foot of the Sierra Nevada. The last spur of the mountains was utilized by the Moors in the creation of a palace and gardens so beautiful of their kind that even the builders were fain to claim a celestial interposition in their behalf.

The street leading to the Alhambra turns from a broad plaza and winds up to the monumental gateway marking the entrance to the palace grounds. Inside of the portal the busy world and its cares seem to disappear, and one breathes the atmosphere of a fairy land which only Irving could rightly describe. Indeed, when in the midst of the gardens, it is at first difficult to say in just exactly what the charm consists. There is certainly no attempt at regularity. On the contrary, there is a studied irregularity observable on all sides. There is a wealth of green foliage, which is carelessly massed about the roadway so as to half disclose its charms and awaken the imagination, or scattered in a seemingly thoughtless manner along the base of the beetling cliff, or clustered on the brow of the steep, inclined roadway leading to the towers. Even the water, which is such a necessary adjunct to all Moorish work, is introduced in an irregular manner. On each side of the road is a dancing, babbling brook, cooling the air and cheering the senses, while tiny waterfalls shoot out unexpectedly from the side of a cliff, to suddenly disappear into a yawning underground conduit. All this work is entirely artificial, but it is so completely in accord with its surroundings, so thoroughly artistic in thought, that it possesses the unstudied charm of nature's best examples.

Altogether, the outer gardens of the Alhambra are as delightfully planned an entrance to a realm of fairy land as could be imagined. The Moorish landscape work and the picturesque mysteries of the palace are revealed little by little. There is no general vista, no all-embracing view, but the imagination is left to picture what is dimly revealed through the trees and across the fountains and under the wide arches, while, as in all Moorish work, the attention is held by unexpected beauties and half-disclosed attractions. This is the key note of the whole arrangement: to awaken interest by unexpected surprises and half-concealed vistas.

The gate-house at the entrance to the inner portion of the Alhambra is an ingenious bit of Moorish arrangement, grand and imposing in general aspect, but adapted to its semi-military purpose. The passage makes two sharp bends in the thickness of the ponderous mass, so as to effectually mask the way, and emerges beyond the gate-house into a steep roadway flanked by heavy battlements, disposed in such a manner as to block the view on all sides except towards the summit, where the Vermilion Towers close the vista with their picturesque solitude. The roadway ends in a broad, open terrace, with the old Moorish Wine Tower on the right and the ugly Renaissance structure erected by Charles V. blotting out the site of the original entrance to the Moorish palace, while all across the front of the terrace is a magnificent prospect over the ravine and along the banks of the Darro towards the *vega*.

It is impossible to say exactly what was the original plan of the Alhambra gardens. Undoubtedly the terrace

was much larger and there was a more magnificent entrance to the palace; but the large terrace, with quiet, shady avenues leading from it, was probably then, as now, the central feature of the scheme. The Moors had a rare faculty for understanding how to adapt their work to natural possibilities. They never neglected an opportunity to make nature help out art, and with their keen, poetic appreciation of beauty of form and color, it is not surprising that the Alhambra should be so wonderful in its charm.

Boston, Mass.

C. H. Blackall.

Foreign Correspondence.

London Letter.

THE most fashionably attended flower show of London is that of the Royal Botanic Society, Regent's Park, but yesterday's exhibition offered a new proof that while great floral exhibitions are increasing in popularity in provincial towns, their glory in London is fading before the increasing counter-attractions on every hand. The chief features were, first, the Orchids, which have seldom been seen in greater abundance or of better quality; and secondly, the hardy, herbaceous flowers, which made quite as fine a show, and certainly seemed to have a greater attraction for the crowd.

For many years these summer exhibitions at Regent's Park have carried the palm for tasteful arrangement and splendid specimens. But I looked in vain for the fine Clematises of Jackman, the gigantic trained Roses of Turner and the Pauls, the huge specimen New Holland plants from Jackson and others, and many more fine things which used to adorn these summer shows. Exhibitors say it no longer pays to show these things, and, therefore, we must be content with more easily grown plants, such as Pelargoniums, tuberous Begonias, Calceolarias and Petunias. The present all-absorbing interest in Orchids is, no doubt, largely accountable for this state of affairs, and this explains why many persons here would not grieve if the Orchid fever should subside a little.

New and rare plants are generally sent in large numbers to this society's show, because exhibitors believe their plants stand a better chance of receiving certificates than at the Royal Horticultural Society, where the judges are more numerous and more critical. New Orchids were very plentiful, no fewer than nine winning certificates, and out of these I select a few of the best. An extremely pretty new Phalænopsis named *Kimballiana* (after one of your orchidists) was shown by Messrs. Sander, St. Albans. To describe it one must compare it with *P. Sumatrana*. It has flowers about one and one-half inches across, yellow sepals, and petals heavily marked with irregular, transverse bands of coffee brown, while the narrow, woolly-surfaced labellum is stained with purple. This is an exquisite little Orchid and was well worthy of the award.

A variety of *P. speciosa* named Imperatrix won many admirers, as it was so beautifully colored, the whole flowers being uniformly tinted with crimson carmine. The spike was unusually long, and branched, and carried numerous flowers about one and one-half inches across. This is quite a gem in Phalænopsis.

Some superb Cattleys were shown by Low, of Clapton, chiefly varieties of *C. Mossiæ* and *C. Mendelii*. The deepest and most richly colored form of *C. Mossiæ* I ever saw was named Claptoniensis. The flowers were above the average size, petals and sepals intensely deep rose-purple, lip almost a crimson, without veins or spots, and no trace of yellow or white whatever. A form of *C. Mendelii* called Firthii is a decided "break" in this species, as the broad, white petals have a conspicuous blotch of purple crimson (much after the same style as Backhouse's *C. Trianae*), while the lip is very large, broad and superbly colored. Another form of *C. Mossiæ* named Gigantea was certificated, its chief merit being its large size, but a variety of *C. Mendelii* named H. Little struck me by the splendor

of its colors, which are too subtle to describe. The beautiful new *Cypripedium bellatulum* was shown by no fewer than four different nurserymen and all obtained a certificate for it. Sander's *Odontoglossum cordatum splendens* is remarkable for the intensity and richness of its flower colors, and connoisseurs might think a great deal of one he showed called *O. Coradinei hemileucum*.

A large crop of new tuberous Begonias from Messrs. Laing of Forest Hill and Messrs. Cannell of Swanley were certificated, and all were very beautiful, as were the Pyrethrums and Pæonies of the Messrs. Kelway. These Begonias are still popular here, and though one would think that the public had been surfeited long ago with "novelties," among them new sorts are as eagerly sought after now as they were ten years ago. Pyrethrums are also very popular, being such fine border flowers, brilliant and varied in color, and so valuable for cutting, as they last such a long time in water. Moreover, the plants have such a long flowering time and by a little management a rich autumn crop of bloom may be obtained. Messrs. Laing, who make a great specialty of Caladiums, showed several new sorts which the judges thought quite distinct and good enough for certificate. What to me was most interesting at this show was a large gathering of new or uncommon shrubs from Messrs. Veitch. They had a host of specimens, chiefly cut branches of things that had not been shown before. Among them was the cut-leaved form of the scarlet berried Elder (*Sambucus racemosa* var. *serratifolia*), which was as elegant as many stove plants. I have watched its behavior in one or two places, both last year and this, and it seems a very hardy and vigorous shrub. *Elæagnus pungens maculatus* has leaves of a bright yellow, broad margined with green of various shades. *E. macrophyllus*, a new species from Japan, is a handsome shrub with broad, ovate leaves, about four inches long, bright green above and quite silvery beneath. One can imagine its beauty in the shrubbery when every breath of wind turns up its leaves and makes the whole bush look like silver. I shall keep this novelty in view, as it will be invaluable in landscape gardening.

Senecio elæagnifolia is a distinct evergreen from New Zealand, with ovate leaves of leathery texture, deep green, with a whitish tomentum beneath. It is well named, as it looks more like an *Elæagnus* than a Groundsel. It is presumably quite hardy at Coombe Wood, near London. *Aralia Maximowiczii* is a beautiful shrub that has proved quite hardy at Coombe, and I hope it will be so in all parts of England, as it is so distinct from other open-air shrubs, having quite a sub-tropical aspect. It is of tall growth, has deeply palmate leaves (five to seven lobed), dark green, with reddish brown leaf stalks. It is a stately plant, yet more graceful than the common *Aralia Sieboldi* (*Fatsia Japonica*), which is perfectly hardy about London and south of it. *A. Maximowiczii* is, I believe, a native of Japan, and is the *Acanthopanax ricinifolium* of Decaisne. The Japanese Maples, chiefly forms of *A. polymorphum*, with feathery foliage, were shown in large specimens by Veitch, and the rich hues of the coppery-tinged forms had a charming effect. Golden-leaved shrubs, such as *Neillia* (*Spiræa*) *opulifolia aurea*, *Diervilla aurea*, *Jasminum vulgare aureum*, together with cut-leaved sorts like *Alnus incana imperialis*, *Rhus glabra laciniata*, gave the group a bright effect, and showed how attractive a tasteful arrangement of hardy tree and shrub branches can be made. Perhaps the most valuable contribution in the way of new hardy trees at the show was a golden form of *Thuyopsis borealis* (*Chamæcyparis Nutkaensis*), exhibited by Messrs. Slocock, nurserymen at Woking, Surrey. The young shoots were of a rich golden hue, and one can imagine what a graceful tree a large specimen would be on a lawn. The original form of this tree is so valuable in ornamental planting that this golden form is most welcome, although, as a rule, I have no particular leaning towards golden or silver forms of Conifers.

June 21st.

W. Goldring.

New or Little Known Plants.

Phlox Stellaria.*

THE peculiar little Phlox which is figured in the present number is one of the rarest eastern species. It was first discovered by Dr. Short, of Louisville, Ky., in 1829, upon the precipitous limestone cliffs of the Kentucky River, though the exact locality is unknown. It has since been found at Fountain Bluff on the Mississippi, in Jackson County, Illinois, and by Dr. Gattinger, of Nashville, in the Cedar-barrens of Tennessee, in Rutherford and Crawford Counties, growing among sphagnum.

It is a low, slender, spreading perennial, perfectly glabrous, with narrowly linear leaves and rather large scattered flowers. The lobes of the pale blue or nearly white corollas are distinctly bifid. The specific name has reference to this resemblance in flowers and foliage to some species of *Stellaria*. It blooms in May or early in June.

Another very similar species, *P. bifida*, is found on the prairies of Illinois and Missouri. It is distinguished by a minute pubescence, and by the deeper division of the lobes of the corolla into two or three oblong or nearly linear diverging segments.

S. W.

A New Station for *Lilium Grayi*.

CLOSE upon Dr. Watson's recent prophecy in GARDEN AND FOREST, that the habitat of this Lily would prove to be not restricted to Roan Mountain and the Peaks of Otter, has followed its discovery by Mr. H. P. Kelsey in an old field on the banks of Linville River, not far from the little village of that name at the foot of Grandfather Mountain, N. C. The station must be very different from the two subalpine ones previously known. He sends half a dozen plants, collected July 1st, which are readily identified with those that grow under the Alders and Rhododendrons of the Roan Mountain, "Bald," and with Mr. Faxon's excellent figure in GARDEN AND FOREST.

Vineyard Notes from Southern New Jersey.

THE prospect for a Grape crop here is, at this date (July 9th), reasonably hopeful in those localities unvisited by the rosebug when the vines were in bloom. Where the rosebug came in force there is nothing left to be harmed by rot or mildew—the vines are fruitless.

The rosebug first appeared, formidably, on my farm on May 22d, 1887. For fifteen years I had seen little of these insects, but had heard of vineyards infested to the entire destruction of the Grape crop for the past ten years. In 1887 the rosebugs seemed to swarm from these old homes, and invaded the Vineland tract, consisting of about 34,000 acres. Some farms escaped, but it is proper to call the invasion general, and it was literally an invasion. The insects do not appear simultaneously everywhere, but they spread from the nidus where the broods are hatched. Thus, in 1887 they first appeared on the west side of my farm, and there swept over 3,500 vines, not leaving a single blossom to form a Grape. They seemed moving from the west, and did not reach a vineyard of 6,000 vines on the east side of the farm until about the time of the limit of their existence. Hence these vines escaped their devastation. Nevertheless, the farm east of mine was infested with rosebugs, and they seemed to increase in destructive effect; towards the east, on this farm, also. Probably this was another swarm. The general tendency of movement of these insects seems to be towards the east.

Of course I tried to repel this onset; applied all sorts of insecticides, but really made no effective defense. The bugs had their way. For several days four men constantly labored to save the clusters on those 3,500 vines, but not one was left to pick in September!

* P. STELLARIA, Gray, Proc. Am. Acad., viii. 252, and Syn. Flora, ii. 131. Perennial, glabrous; stems slender, tufted, or creeping at base, low and branching; leaves linear, one or two inches long, rather rigid, slightly ciliate at base; flowers scattered on rather long peduncles, pale blue; corolla-lobes narrowly cuneate, bifid at the apex; ovules solitary.

This spring (1888) I arranged beforehand to meet the invasion. Commissioned by the United States Department of Agriculture as "Special Agent in the section of Vegetable Pathology, to make experiments in the treatment of the fungus diseases of the Grapevine," and "to report on the same," I had in the conduct of these experiments made the accidental observation that certain preparations of copper-sulphate seemed distasteful to the rosebug, which abandoned vines to which this poison had been applied. With the hope that I might have discovered a remedy, I compounded, early in May, the various formulas of copper-sulphate designed as preventives of vine diseases; applied them to the Experiment Vineyard, and also May 29th, so far as opportunity permitted, to other of my vines which had been devastated by rosebugs in 1887. June 5th, 1888, the rosebugs came again; where they were worst the previous year, they most abounded this year.

Those vines sprayed with the copper solutions May 29th were the least infested. Whether this protection was due to the presence of the copper-sulphate on the leaves and clusters, or whether the absence of the bugs from these poisoned vines was merely accidental, I cannot say. However, on a patch of Concord (1,500 vines), about 100 yards distant from those which were sprayed with the copper, the rosebugs took the entire crop! I lacked the time to take care of this vineyard. The vines were simply pruned and fastened to the stakes. The ground was not even plowed. When the rosebugs had full possession here (about 500 bugs to the vine), I experimented with insecticides. I sprayed two rows with a solution of London purple, two rows with a solution of Paris green, both strong enough to badly burn the foliage. A row was dusted with a "bug powder," which has been advertised, and another row with another powder. The remaining rows of the vineyard were sprayed with the various copper-sulphate solutions which I had previously employed on other vines. In addition to these treatments I exhausted my knowledge of chemistry and the toxicological pharmacopœia in attempts to combat the insect. No benefit came from anything tried. When the rosebugs were done not a grape was left! Last week I had the vines grubbed out.

The vines which I have saved (and they are several thousand, now loaded with fruit, and which were infested with rosebugs) are trained on a single wire trellis.

Anticipating the advent of the enemy, and for fungus disinfection, I had the ground beneath this trellis scraped smooth with hoes. When the bugs pervaded these vineyards I sent men, armed with broad wooden paddles made of half a barrel stave, along the rows. A sharp tap of the paddle on the underside of the wire would cause the bugs to fall to the smooth surface of the ground beneath; another sharp stroke of the paddle disposed of them finally. In this manner we daily went over some 10,000 vines for two weeks, and killed rosebugs by the bushel, and in this way I consider I have saved the crop I have. This bug-killing can only be effective in the early part of the day, say up to 9 A. M. Disturbed suddenly in these early hours they will fall to earth and lie still; later in the day they will take wing.

From one small Grapevine, badly infested, I took pains to catch in a basin of kerosene (which kills the insect) and to count the number of rosebugs. There were 1,627! Next day I inspected this vine again, and rosebugs were as plenty on it

as at first! I have a white Rose for which these bugs have a fondness. When this bush bloomed the rosebugs deserted the neighboring Grapevines for it. I have counted 100 bugs on a single flower, clustering over it so as to hide it. I made this bush a 'martyr to science,' and drenched and sprayed it with all known insecticides, including the bichloride of mercury. I powdered it with all the powders, from white hellebore to carbolated lime. Riley's Kerosene Emulsion caused the bugs to fly away promptly, but they were back again in an hour, and in spite of all my applications they devoured every rose on the bush.

I conclude that the only practical way of getting rid of them (and this at times will be impracticable) is to crush them.

There is a comfort, however, to be drawn from a visit of rosebugs to the vineyard—its proprietor is relieved of all anxiety concerning the black rot.

As for me, I have got past Scylla, and am now worried about Charybdis. I have forty or fifty tons of Grapes yet, and the black rot has appeared! Concerning this, what we have done to prevent it, and what we purpose to accomplish, I will leave for another letter. We have modified practice in prevention of rot and mildew this season, but it is yet too soon to speak otherwise than hopefully of the patient.

Vineland, N. J. *Alex. W. Pearson.*

The Fruit Garden.

THE setting of new Strawberry beds is now in order. With good plants from one's own grounds, a favorable season, and proper care henceforward a good crop may be reasonably counted on next year. Sink two or three-inch flower pots in the ground till the rims are even with the surface, upon each one place a "joint" from a runner and hold it down with a stone. When well rooted sever it from the parent plant and turn it out of the pot into the place intended for it.

Potted plants from one's own ground are worth double those purchased from a distance, many of which are not allowed to get sufficiently rooted before they are sent out. In such cases good "layer plants"—as plants rooted naturally are termed—are far better.

Beds of three rows, fifteen to eighteen inches apart and the plants the same distance in row, make a very convenient bed for a small garden where the culture is by hand entirely. It is not a bad practice to mow off the tops of old beds, especially if they have

been troubled with the rust or blight of any kind, and when dry burn them where they fall. If evenly spread over the bed the fire will not injure the crowns of the plants, and will destroy the fungus and perhaps some insects at the same time. In a few weeks the new growth will present a vigorous, healthy appearance, and the plants obtain a rest that seems beneficial.

Raspberry and Blackberry canes should have been beheaded when two or three feet high so as to make them stocky and branch low. The ends of the branches themselves should be pinched off once when they are four to six inches long. This doubles the bearing capacity of the plant near the trunk, enabling it to bear its burden with greater ease than if left to grow unchecked.

It is not always safe to pinch these branches more than once, for fear the after growth will not mature sufficiently to pass the winter without injury. It should all be done this month, and is unsafe if delayed later.

Grape vines should be watched for insect depredators and

Fig. 42.—Phlox Stellaria.—See page 256.

black rot, and all affected berries should be picked off and buried or burned. If dropped on the ground the spores of the *Phoma* mature and are on hand to renew the attack next season. Bagging Grapes is growing in favor among amateurs, but it should have been done last month to insure safety. It would not now save berries from rotting if the infecting germs are already present, but it will protect against the depredations of birds.

E. Williams.

Montclair, N. J.

The Vegetable Garden.

IN marking off the rows for Cauliflower, Brussels Sprouts, and the like, draw drills as if for sowing Peas and plant in these. The drills are useful in holding water and after a hoeing or two are leveled up. In setting out these plants, Lettuces or other crops, do so in dull weather or in the afternoon in sunny weather, and after planting give a good soaking of water. In planting Leeks, dibble them in moderately deep and also in furrows. By planting them in furrows and drawing the earth up to them as they advance in growth, the long white necks so desirable in this vegetable are secured. Tomatoes are now in vigorous growth. Thin their branches and shorten their laterals a little to give the fruit the benefit of a free circulation of fresh air, and thus, in considerable measure, prevent rotting, but do not expose the fruit to sunshine, else they may get scalded. Perfection, Acme, and selected Trophy for summer, and Winter's Early Essex for forcing in winter, are capital sorts, but there seems to be a good deal of confusion in the names of Tomatoes, and, indeed, the Tomatoes intermix so much as often to lose their varietal identity. As soon as early Potatoes become ripe, which is indicated by the stems dying off, lift them and use the ground for some other crop, as Celery, Cauliflower, Carrots or Strawberries. Should early Potatoes remain in the ground after they are ripe, a soaking rain succeeding dry weather will start a second growth, and thus render the tubers of inferior quality; on the other hand, in storing these early Potatoes, great care must be used; a cool, airy, moderately dark place is necessary, and the tubers should be stored only in small bulk. It is not advisable to raise any more of a very early Potato crop than can be disposed of before September.

In order to maintain vegetable crops in their most vigorous condition, the ground must be kept clean and well stirred about them, whether it be dry or moist, only do not stir the ground in wet weather. In many large gardens the plow is used; in most private gardens the hoe is used. In summer cultivation, plow shallow or hoe deep is good advice, for it takes very deep hoeing to be as deep as shallow plowing; and in summer weather, when the ground is dry and hard, deep hoeing, although hard work, is very necessary. In clean ground, raking is as good as hoeing and much quicker work. The long, steel-toothed, bow-rakes are most excellent tools for this work; they tear through the surface soil in fine style and leave it loose and mellow; they also root out and expose to the killing influence of warm sunshine all young weeds that may be germinating. Where the rows are narrow and the ground hard, and it is necessary to break it deep, the Hexamer or prong-hoe is an excellent implement.

Glen Cove.

The Fritillaria.

WHEN taking a few notes amongst the bulb gardens in Haarlem and its vicinity, I visited, amongst others, the celebrated hardy plant nursery of Messrs. Krelage & Sons, in Haarlem. At that time—end of April—the leading feature in the nursery, besides the ordinary Hyacinths, Tulips, etc., were the Narcissus and Fritillarias. The last-named have been cultivated here for many years, and a very large space of ground is set apart for the varieties of *F. meleagris*. It is an old English garden plant, and one that was much esteemed when exotic plants were scarcely heard of. There is some variety of coloring found amongst them, from pure white, or white with a greenish tinge, to the usually maroon-purple checkered varieties. Probably the numerous forms in the possession of Messrs. Krelage have been produced by crossing other species with it. The deep yellow ground on some might claim the parentage of *F. Moggridgei*, and others that of *F. Pyrenaica*, but it may not be beyond the art of the hybridist to produce the whole of them from the common species—*F. meleagris*. Some varieties are very tall and vigorous, others are dwarf and not at all free in growth; but, like delicate children in some families, they may be even more valued on that account.

There might be good stocks of some half hundred varieties,

and I went carefully over them, noting the most distinct in growth and flowers. The colors range from pale yellow with scarcely any markings upon them to rich chocolate heavily checkered. Theresa Schwartze is a pale form, marked with brown on yellow ground; Paul Kruger is glossy chocolate, heavily checkered; Arentine Ardensen, greenish-yellow, checkered reddish-brown; Mr. Dullert, crimson-brown, heavily checkered; Siege of Haarlem, greenish-yellow, slightly checkered a reddish-brown color; David Blès, yellow, faintly checkered red—a dwarf-growing variety; Stieltjes, heavily checkered maroon and yellow—a vigorous plant; Van Lerijs, medium, blood-red checker, vigorous in growth; Alma Tadema, pale greenish-yellow, with rosy-red and medium-sized checker; Rembrandt, maroon-crimson heavily checkered; E. H. Krelage, heavily checkered chocolate-red on yellow—an excellent plant; W. J. Holdwijk, rich maroon-crimson, heavily checkered. The above are a dozen of the best varieties which I noted in the collection. Some two years ago this firm sent a selection of them to be inspected by the Floral Committee of the Royal Horticultural Society, and these were greatly admired at the time by some members of the committee, and selections from them were awarded certificates, but cut flowers that had made a long journey, and were crumpled and faded, gave a poor idea of the beauty of the flower, and the effect produced when seen in masses of varied colors.

Fritillarias are grown without much trouble, their place being in the herbaceous border, where they should be planted in groups, and allowed to remain undisturbed for several years. A deep, sandy loam, moderately moist, is better for them than a light, shallow, or gravelly soil.

I have grown several distinct species in pots, also the white and ordinary forms of *F. meleagris*, with success, the flowers being greatly admired, coming as they do before any are in flower outside. Repotting should be done annually, but the bulbs themselves should not be disturbed until in the course of time they become too numerous, and therefore crowded.

—J. Douglas in *Gardeners' Chronicle*.

Cut Flowers in Midsummer.

ALTHOUGH out-door gardens may in midsummer be bright and gay and pretty enough, cut flowers for indoor decoration are also needed in abundance. We cannot gather blossoms from Coleus or Alternanthera and House-Leek beds, for these plants in pattern beds are not allowed to bloom; and we should not gather the flowers from the Geranium or Heliotrope beds, because the more blossoms these plants carry in the beds, the better do they serve the purpose for which they have been planted. But in mixed borders or reserve gardens should be grown an ample quantity of such plants as yield a generous supply of flowers that are desirable and well adapted for cutting. While at all times during the summer we may have many sorts of flowers, there are always a few sorts in their season that are in more demand than others, hence should be grown in larger quantity. This is often a matter of taste; different persons have different preferences. Just now the main crop of cut flowers consists of Sweet Peas, Mignonette, Heliotrope, double white Feverfew, Hollyhocks, small-flowered Sunflowers, Drummond Phlox, scarlet Pelargoniums, Rose Geraniums, annual and perennial Coreopsis, Nasturtiums, Candytuft, Ehemans' Canna, and the narrow-leaved, yellow Day Lily (*Hemerocallis graminifolia*). These may be supplemented by a great variety of other flowers—for instance, Zinnias, French and African Marigolds, Ten-week Stocks, Indian Pinks, Garden Pentstemons, Verbenas, Poppies, Larkspur, Bellflowers, Veronicas, Cosmos, Butterfly Weed (*Asclepias tuberosa*) and many Lilies, as *L. auratum*, *L. longiflorum* and *L. Humboldtii*. *Euphorbia corollata* and *Gypsophila paniculata* are now in their prime and very useful for adding a light and airy effect to other cut flowers. Although Dahlias are regarded more as autumn than summer flowers, they may now be had in tolerable abundance. The earliest planted Gladioluses are in bloom. *Montbrietia crocosmiflora* has beautiful, orange-colored flowers and should be grown in quantity for summer flowers. It is tender, but wintered in a warm frame or cool green-house, and divided and planted out-of-doors in summer, it grows and blossoms very freely. Unlike most other bulbous plants used for summer gardening, it should be kept growing all winter. In the same way the finer Cannas should be kept growing somewhat in winter, if we want a large increase of stock.

In order to maintain the crop of flowers in their best condi-

tion, keep the ground scrupulously clean from weeds and the earth well loosened about the plants. Remove decaying leaves and flowers, support very neatly, with string and stakes, all plants requiring the same, prevent overcrowding, and as soon as perennials have done blooming cut them over, so as to give the other occupants of the borders more room. As soon as Drummond Phlox, Mignonette, Stocks, or other annuals are past their best and begin to appear seedy, remove them, fork over the ground, and at once replant with Marigolds, scarlet Salvia, Zinnias, Drummond Phlox, or China Asters previously prepared for this purpose; or sow some Mignonette, Sweet Alyssum, or other annuals that will have plenty of time yet to grow and bear a good crop of flowers before frost may destroy them.

Many people have a passion for saving seed. This is well enough and our own saved seeds are just as good as those we buy, but the question is, Is it worth while? Plants bearing seed occupy room that might be used by plants coming into

Phlox Stellaria, of which a figure is published on another page of this issue, is an excellent rock-garden plant, making handsome carpets of pleasant green, which, in the latitude of Boston, where this plant is perfectly hardy, are covered late in May with flowers quite unlike in color those of any other Phlox in cultivation. It spreads much less rapidly than the Moss Pink (*Phlox subulata*), but its habit is very similar, and it is propagated in the same way by cuttings or by division. C.

Plant Notes.

Japanese Iris.

ONE of the most attractive features in Mr. John L. Gardner's beautiful garden in Brookline, Massachusetts, is the bed of Japanese Iris (*Iris laevigata* or *Kempferi*), which forms the subject of our illustration.

A Bed of Japanese Iris.

flower, and seeds of common flowers cost very little. Of course, it is well to save seed in the case of extra choice or rare varieties, or of sorts not easily obtained, or of expensive kinds that we can save with little trouble. Another point in seed-saving is this: In private gardens the choice blossoms are used as cut flowers, and whatever are left to go to seed are the lateral, second-rate, or poor flowers, which give inferior seed; seed-growers, on the other hand, assiduously preserve the best flowers for seed, cut off and throw away the poor flowers, and root out and destroy all plants bearing poor varieties of flowers.

Watering plants in dry weather requires attention. It may be impracticable to water all the plants in the garden, but we should give, and that liberally, to Dahlias, Asters, and such others as suffer much from drought. Never water plants while the surface of the ground is hot or the sun is shining brightly on them; and in giving water, give enough to penetrate deep into the earth.

William Falconer.

The plants, which were selected in Japan with great care by Mrs. Gardner, represent the best named Japanese varieties. They are arranged according to color, in the Japanese fashion; each row across the bed consisting of one variety, those with white flowers at one end, and then all the intermediate shades to the dark blues and purples at the other end. The bed is sunk eight or ten inches below the surface of the surrounding lawn, and is furnished on one side with a perforated water-pipe so that the plants can be irrigated during the growing season. It is eighteen inches deep and consists of a rich compost of loam and thoroughly rotten cow-manure, and every year it gets a good top dressing of manure. Every pleasant morning after the middle of May the water is turned on at nine o'clock and allowed to run till three or four o'clock in the afternoon; by that time the

bed is thoroughly saturated and covered to a depth of two or three inches with water; the supply is then shut off until the next morning. Some of the varieties, under this generous treatment, grow to a height of five or six feet, and have produced flowers fully ten inches across, and surprising in their profusion and beauty. While irrigation is doubtless necessary to develop the greatest perfection of the Japanese Iris, it can be successfully grown in this country in ordinary seasons in any good garden soil and without artificial watering. Very fine flowers have been produced without special treatment by Mr. Parkman and other American growers, who have raised good seedling varieties of this plant without giving to it more care than is required by other Irises. The Japanese Iris is one of the handsomest of the whole genus, and, when in flower, one of the handsomest of hardy perennial plants. It is beloved by the Japanese, who make holidays to visit the Iris beds when the plants are blooming, and who have devoted infinite pains to its improvement. The flowers are hardly surpassed in delicacy of texture or in beauty of color, but they do not appear here until July, and the hot sun soon fades them. The blooming season may be prolonged by the use of an awning placed over the beds during the day, but it cannot be denied that this plant flowers too late here, and that its period of beauty is too short in this climate ever to make it a great popular favorite. It is hard to imagine, however, anything more beautiful than a mass of these many tinted flowers like that which our illustration represents, and which certainly has no equal in the United States, either in the varieties which it contains or in the perfection with which they are cultivated.

Notes from the Arnold Arboretum.

THE European Privet (*Ligustrum vulgare*) is in bloom. This is such an old-fashioned shrub, and such a common one, having long remained the favorite hedge plant in the Northern States before Conifers were as much planted for hedges as they are now, that few people realize, perhaps, what a valuable plant it is or how numerous are its claims upon the attention of the planter. There is not a shrub more hardy, or one less fastidious in regard to soil; it blooms profusely at a season of the year when comparatively few shrubs are in flower; it is little affected by drought, and therefore invaluable for planting under or near large trees, which quickly exhaust the moisture in the soil, and so make it difficult for other plants to thrive near them; and in autumn it is covered profusely with handsome black berries, which remain bright and unwithered upon the branches until the new leaves appear the following spring. The Privet, like the Barberry, has gradually become naturalized in some parts of the Eastern States, through the agency of birds, no doubt, and seems to adapt itself now to its surroundings as completely as any American plant; and, like the Barberry, it can be planted in connection with our native shrubs without raising any question of want of fitness or naturalness of grouping or composition. Several varieties are cultivated. There is one with yellow fruit, which has now become naturalized in the neighborhood of Boston. There is one with pendulous branches, which, when grafted standard high, makes an excellent small weeping tree; and there are forms with erect growing branches, giving to the plant a fastigate habit, and with golden, blotched leaves.

Ligustrum Ibota is a Japanese and north China Privet, and a valuable, hardy shrub, of graceful habit, just now covered with flowers. It has erect, softly pubescent branches, ovate-elliptical, obtuse leaves, and a slender thyrsus of small white flowers, with a long and slender corolla tube. It is a variable species; at least there are two forms here of what is evidently the same species, one with leaves two inches long on short petioles, and a slender, erect inflorescence three inches or more long. In some collections this is known as *Ligustrum Amurense*, under which name it is very well figured and described by Carrière in the *Revue Horticole* for 1861, p. 352. The other variety has leaves rarely an inch and a half long, more oval in outline and with shorter petioles, while the inflorescence is less than an inch long, few-flowered, and often one-sided and nodding by the curving downwards of the peduncle.

Ligustrum ovalifolium is another Japanese species belonging with the last to the section of the genus with long-tubed flowers. It has been of late years very widely distributed in American gardens under the name of *L. Californicum*, or the California Privet, a name which it perhaps owes to the possible fact that it reached eastern nurseries first from California, where it has been very generally cultivated for several years. It is a hardy and free-growing shrub, with erect branches, five or six feet high, covered with handsome oval or ovate-elliptical, bright green, shining leaves, which do not fall until late in the winter. The small white flowers are produced in abundance. Like all the Privets, it is easily propagated from cuttings—so easily that it has become a great favorite with nurserymen; and certainly no other shrub of such comparatively recent introduction has been so widely and generally cultivated in this country.

Not the least attractive adornment of many old-fashioned New England door-yards is *Spiraea sorbifolia*. Unfortunately, it is rarely seen nowadays anywhere else in this country, for it is a noble plant, forming, with generous treatment, a great mass of dark green foliage, six or eight feet high by as much through, and now covered with immense panicles, fully two feet long, of small white flowers. The leaves are pinnate, with reddish stems, fifteen to eighteen inches long, and composed of about ten pairs of acuminate, sharply serrate leaflets, with prominent veins. The flower clusters are produced on the ends of vigorous branches of the year, which often attain a length of three feet before the flowers appear, and are quite red. It is a common and widely distributed Siberian species, reaching Japan, and the earliest to flower here of the plants of the small section *Sorbaria*, which some botanists now separate from *Spiraea* as a genus. They all have pinnate leaves and large terminal panicles of white flowers. They are Asiatic, generally Siberian, with one species confined to the Himalaya and one in Mongolia or northern China. *S. Lindleyana*, the Himalayan species, a handsome plant in English gardens, where it sometimes attains almost the size, and the habit of a tree, is not hardy here, being cut down to the ground every winter, and never flowering.

Spiraea Japonica, as defined by Maximowicz and made to include *S. callosa* and *S. Fortunei*, is an exceedingly variable species, widely distributed from Japan (where it was first made known) to northern China and the Himalayas. It contains forms (especially those referred to *S. Fortunei*) of very considerable garden value, and among those in the collection here some are in flower from the end of June until frost. One now in flower and the earliest is of Japanese origin and seems identical with the plant figured by Hooker in the *Botanical Magazine* (t. 5164) as *S. Fortunei*. It is a spreading, flat-topped shrub, four or five feet high, with reddish glabrous branches, the young shoots puberulous, dark green leaves, paler on the under side, five or six inches long, elliptical-lanceolate, with a long acumen, and glandular serratures. The flowers are rosy purple, arranged in a lax, flat cyme with slender spreading branches and more than a foot across. The disk, as is the case with the flowers of all the forms of this species, is provided with a row of small, sub-erect red glands. It is a hardy, free growing plant not particular about soil; and one of the best of the forms of *S. Japonica*.

The opinion is frequently expressed that the European Heaths are not hardy in this country, or that they are difficult to manage. There is a large collection of these plants in the Arboretum, where they grow well and flower freely every year. They are planted in an exposed, sunny position, and in soil with which a considerable amount of peat has been mixed, and they receive in winter a covering of Pine branches. Young plants—and this is true of many garden shrubs—flower better than old ones, and it is found advisable to renew the collection occasionally with new plants. The earliest of the summer-blooming species in flower is *Erica Tetralix*. It is a dwarf plant of grayish hue, six or eight inches high, with minute, ciliated leaves arranged in fours and pale red flowers in terminal heads. It remains in bloom nearly all summer. The hardy heaths are all capital rock-garden plants and they make good edgings for beds of larger evergreens.

The Silky Cornel (*Cornus sericea*) is one of the latest of the North American Dogwoods in the collection to flower. The remarks which have been made in earlier issues of these notes regarding the value of our larger growing native shrubs for planting in public grounds, are as applicable to this plant as to the other Dogwoods and to the Viburnums. Like *C. stolonifera*, it is handsome in winter with its purple branches. It has ovate pointed leaves, silky downy on the under side, close, flat, rather small cymes of yellow-white flowers and pale blue fruit. It is very common at the north along the borders of

swamps and in other low, wet places, where it forms a wide spreading bush eight or ten feet high.

Rubus odoratus, the Flowering Raspberry, is another useful native shrub. It has upright stems four to five feet high, covered with bristly, glandular hairs, three to five lobed leaves, and handsome, dark rose-purple, clustered flowers, more than an inch across when expanded. It is a common northern plant, spreading rapidly here in cultivation by underground shoots, and soon forming almost impenetrable masses of dense stems and foliage, now gay with bright colored flowers. It thrives, too, under trees, and is one of the best plants to cover shaded ground rapidly in situations where such a tall growing plant can be properly used.

Rubus Nutkanus, which resembles the common Flowering Raspberry in foliage and in general habit, but with white flowers is not hardy here, and is killed down to the ground every year, and therefore does not flower. It is found from the shores of Lake Superior and westward to Puget Sound and British Columbia.

Itea Virginica is now in flower. It is a dwarf shrub, rarely more than a couple of feet in height. The simple, upright, terminal racemes are not very showy, but it is an interesting plant as the representative of a peculiar tribe of the Saxifrage Family, and it flowers when shrub flowers are less abundant than they were a month ago. It grows in low, wet places from New Jersey southward near the coast.

The three species of *Ilex* belonging to the section *Prinos* which are found in the Northern States are now all in flower. Their chief ornamental value no doubt consists in their showy fruit, but they are not without attraction in flower, especially *I. laevigata*, which is much the rarest species, and which may be distinguished from the common Black Alder (*I. verticillata*) by the long stalked sterile flowers, and by its larger fruit, which ripens somewhat earlier in the autumn. They are both easily cultivated, and worth much more attention at the hands of gardeners than they have ever received for the brilliant and abundant fruit which covers their branches in winter. The Ink Berry, *Ilex glabra*, is a handsome evergreen shrub, with black berries. It occupies considerable tracts of sandy soil near the coast from Massachusetts southward, notably on Cape Cod and on Long Island, and it is often found along the borders of ponds and streams in the Pine woods, where it grows much taller (four or five feet sometimes) than on the exposed sea coast. This is one of the few broad-leaved evergreens of the Northern States; it assumes a compact habit in cultivation; its foliage and its fruit are both handsome; yet although it was introduced into England one hundred and thirty years ago, and has always been grown in foreign nurseries, it is practically unknown in American gardens, and its value seems to have been never appreciated by planters in this country.

Andromeda ligustrina is not a showy flowered species, but it can be used, perhaps, with advantage, to give variety to a plantation of native shrubs, and it will thrive in low, wet ground, where it reaches a height of eight or ten feet and produces at this season of the year an abundance of racemose-panicled, rather small, pure white flowers. The ovate-oblong deciduous leaves turn brilliantly in autumn.

One of the most beautiful of our native Roses now in bloom is *Rosa nitida*. It is rather a rare plant, found from Newfoundland to eastern Massachusetts, and although distinguished and described long ago and even introduced into Europe early in the century, it has been but little known in this country, and has, until quite recently, been confounded with other species. It is one of the most distinct, nevertheless, of the American Roses, and may be known always by the red shoots, thickly beset with slender red spines, barely stouter than the red prickles. The leaves are bright green and shining, and make a charming contrast with the bright, rose-colored or red flowers, one and a half to two and a half inches across. *Rosa nitida* inhabits damp swamps and other low, wet places, but transferred to the garden, like most of our native Roses, it grows freely, soon making a broad mass of foliage and flowering with the greatest profusion. There are few shrubs better worth a place in the garden.

Alyssum gemonense is a dwarf under-shrub, a native of southern Europe, and quite hardy here. It grows a few inches high, and the base of the stems only are woody. They are covered with small, lanceolate, entire leaves, clothed with grayish, stellate down, which gives them a velvety appearance. The yellow flowers are produced in close, terminal cymes, which quite cover the plants giving to a mass of them a showy appearance, which they retain during several weeks. This is an excellent dwarf rock-garden plant.

The Forest.

The Long-leaved Pine.

THIS widely distributed tree (*Pinus palustris*) forms almost exclusively the immense forests of the lower Southern Pine Belt, which with scarcely any interruption cover tens of thousands of square miles. It furnishes not only enormous supplies of valuable timber, but is also the chief source of the resinous products of North American forests. It is therefore first in importance amongst all the trees of the southern division of the Atlantic forest region.

From the northern confines of North Carolina, the forests of Long-leaved Pine extend in a belt, varying from 90 to 120 miles wide along the coast of the Atlantic States, to Florida, crossing the Peninsula to the Everglades, and from western Georgia following the shores of the Gulf of Mexico to the bluffs of the Mississippi River. One vast forest of Long-leaved Pine covers the belt of gravelly and sandy drift soils from 5 to 25 miles in width, which traverses Alabama from its eastern to near its western borders. On detached patches of the same formation such forests reach in that state the 38th degree of north latitude at an elevation of about eight hundred feet above the sea. West of the Mississippi River this belt appears beyond the alluvium of the delta on the drift covered uplands. The magnificent forests of Long-leaved Pine of the western Gulf region stretching from the Pachita river to the valley of the Trinity in Texas and from the thirty-second degree of north latitude to the savannas and marshes of the coast are unsurpassed in the luxuriance of their growth and their timber wealth.

Provided with a powerful taproot, the finely shaped trunk of this tree rises in the fullness of its growth to a height of 100 to 115 feet, with a diameter of 24 to 32 inches near its base, and free from limbs to one-half or two-thirds of its length. The massive, horizontally spreading limbs, rarely exceeding 20 feet in length, divide into short gnarled branches, forming an unsymmetrically shaped head which affords but a scanty shade to the ground beneath. The leaves to the number of three in a sheath of a rich glossy green and from 8 to 12 inches in length, are shed during their second year, and therefore with the increasing shortness of the axis of annual growth are crowded at the extremities of the otherwise naked branches in dense tassels or tufts. The edges of the bracts being fringed with fine, long, silky hairs, provide the densely crowded leaf buds terminating the branches with a soft covering of silvery white, by which this species is readily distinguished at first sight from its nearest allies.

The flowers, situated near the apex of the young shoots of the season, make their appearance early in the spring. The staminate flowers in great abundance and chiefly on the lower branches, discharge their copious pollen here about the middle of March. The pistillate flowers being chiefly confined to the upper part of the tree, are fully exposed to fertilization by the pollen of other individuals. They are in some years much more abundant than in others, and at times almost entirely wanting for a series of years, to the complete failure of the crop. The long, slender, slightly bent cones ripen during the second year, and shed their seeds late in October. These afford a rich mast eagerly devoured by many denizens of the forests. If at this season the weather continues wet and warm, the seeds sprout in the cone and the crop is lost.

After fruitful seasons, which are observed to happen at intervals of 3 to 4 years, seedlings spring up in the openings of the forest wherever the rays of the sun can reach the ground, the seeds sprouting soon after having fallen. In the following season the plantlet produces dense tufts of its secondary or foliage leaves, the stem scarcely rising above the ground. During the succeeding three or four years its growth is very slow, being rather directed to the early development of a powerful root system. At the end of that period the tufts of the leaves of the young Pines scarcely reach above the surrounding herbage. The simple stem having by this time attained a certain thickness, now increases suddenly in height. In the course of the following years irregular branches are thrown out which, somewhat before the tenth year, begin to form regular whorls. Trees ten years old average twelve feet in height. During the next fifteen years growth proceeds at the most rapid rate. At the age of twenty-five years the trees average from forty to forty-five feet in height, with a diameter rarely exceeding ten inches. At a hundred years of age they measure from seventy to eighty feet in height, which during the next half century increases to over ninety feet, with a diameter of sixteen to eighteen inches three feet above their base. From this age to the second century of its life, the Long-

leaved Pine furnishes merchantable timber of the required standard, that is, logs twenty-four feet long and fifteen inches across the smaller end. Trees furnishing square timber in lengths from thirty-five to fifty feet, with a uniform diameter exceeding fifteen inches, show from 250 to 300 rings of annual growth.

Under such conditions of growth and under the continually increasing strain to which they are subjected to meet the demands for their products, the reproduction of these Pine forests is not keeping pace with their depletion. Considering the ever-increasing drafts upon them under wasteful and destructive methods of management, considering devastation caused by the tapping of the trees for their resin, and the damage inflicted by recurring forest fires and by live stock involving the total destruction of the young growth, the prospect of their maintenance seems hopeless and their destruction cannot be long delayed.

Other causes are contributing to the same result and weaken the chances of the Pine for survival in its struggle with competing species during the earlier stages of its life. If the removal of the original growth of Long-leaved Pine happens to be succeeded by a series of barren years, the soil is overgrown by a stunted growth of deciduous trees which completely shade the ground and exclude forever the offspring of the Long-leaved Pine. Towards the northern limits of the Pine belt where the Long-leaved Pine is associated with various deciduous trees, with the Short-leaved and the Loblolly Pine, it invariably succumbs in the struggle to gain a hold on the soil. In the damp flat woods of the coast plain from Georgia to the Mississippi River it is replaced by the Cuban Pine, the Loblolly Pine taking possession of the lands thrown out of cultivation.

According to the returns obtained for the few years at the points of export the products of the Long-leaved Pine in lumber, square timber, and naval stores shipped annually by water and by rail to foreign ports and distant domestic markets, represent fully twenty million dollars. And this sum would be vastly increased if the value of the same products consumed near the centres of production in charcoal, railroad ties and lumber of inferior quality were estimated.

Mobile, June 1st, 1888.

Karl Mohr.

Correspondence.

Prospect Park.

To the Editor of GARDEN AND FOREST :

Sir.—I was delighted to see your recent editorial calling attention to the beauties of Prospect Park and the dangers which threaten them. Too few people in Brooklyn, not to speak of New York, realize what a paradise of beauty lies at their doors. The distance which must be traversed, largely over bad pavements and through rather disagreeable precincts, before a New Yorker is able to reach Prospect Park, is sufficient to explain, perhaps, why a far more beautiful park than the Central Park is so seldom visited by those who throng the drives and walks of the latter. But even the accessibility of such sea-side resorts as Coney Island seems insufficient to account for the indifference of the residents of Brooklyn. I have never visited Prospect Park on Sunday, but I am told that even then it presents a very different appearance from the crowded condition of Central Park, and on a week day its wide roads almost empty of vehicles, its immense lawns trodden but by a few scattered children, and its shady outdoor restaurant occupied by scarcely half a dozen persons, are in strong contrast to the populous gaiety which one sees not only in the park of New York, but in those of Chicago, Philadelphia, and, I fancy, all other great towns but Brooklyn. One cannot help grudging Brooklyn the possession of the finest park in the country, and cannot help fearing that it will suffer at the hands of Commissioners who are so little restrained in their acts by any strong sentiment or interest on the part of the public.

It seems, however, as though the injury thus far worked had been more in the way of acts of omission than of acts of commission. In every part of the park one sees plantations which loudly cry for thinning—which have already suffered much and in the next few years will suffer very much more, from overcrowding. In some places, moreover, the presence of dead or dying Conifers—chiefly Spruces and Pines—conspicuously mars the effect of lovely landscapes. But not nearly so many such trees were planted here as in the Central Park, and, consequently, the total injury to their effect which they work is by no means so grave.

The present Park Commission, however, as your editorial states, has resolved upon a more vigorous course of action than that pursued by its predecessors, and it is time to keep one's eyes open for faults of commission. It has, indeed, been asserted from more than one quarter that they are already conspicuously apparent—that, for example, the bordering plantations of the park have already been so badly treated in some places that a view of the shabby encircling streets is admitted. I doubt whether these charges are just. There are certainly a number of places to be found where the bordering plantations are so thin that they may be said hardly to exist; but in all those I found during two visits made to the park for the especial purpose of examining into this point, their thinness seems to be due not to the cutting out of vigorous trees, but to the gradual decay of the plantations. The Conifers largely chosen for this particular purpose stand to-day as miserable perishing little trees, hideous in themselves and pensive to the eye in every direction. Perhaps much cutting has in truth been done in places such as these, but if so, it is probable that it has been merely in the way of removing even worse specimens than those which remain. No soul alive would be so foolish as to cut down flourishing trees and leave such little forlornities as these. The remedy for the nudity of such spots is not to be found in the careful preservation of their existing growths, so much as in sweeping them away and planting *de novo* with trees better fitted to survive and grow into effectual screens. Of course there may be other spots along the borders of the park where flourishing plantations have been massacred, but I failed to find them.

As regards the abandonment of the original scheme for putting a music-stand on the little island near the terrace, I think your words will be re-echoed by all who know Prospect Park. The effect of music heard upon or across the water is proverbially beautiful, and the promenades and concourses on and near the terrace lie in such a way that I cannot conceive there would be any bad acoustic results. It should be remembered that the music rendered in such a place as this is not, as a rule, need not be, and, in truth, ought not to be, of that serious and subtle sort which demands for its right understanding the acoustic properties of a well-built, enclosed auditorium. It is heard, generally speaking, by a different class of music-lovers from those who pay for admittance to such auditoriums; and, whatever the class, it is listened to in a different spirit. Persons who are eating and drinking or walking, driving or rowing out-of-doors, demand music which is merely a pleasant gay accompaniment to their actions and their conversation—music of a light character, and of a sort which does not demand perfect acoustic conditions any more than it demands close and exclusive attention. Of course even under these circumstances music distresses instead of pleases the ear if it is heard as intermittent puffs of sound broken by lapses of silence or if only its strongest notes are perceived. But except in a strong wind there seems no reason why this effect would be produced by a band playing on the island; in a strong wind it will be produced in any out-door situation where large masses of foliage exist; and that such masses should exist is essential for the comfort and pleasure of those who are to listen. The best place, acoustically, for a music-stand, would be in the centre of the largest open lawn that could be found; but who would care to stand or sit in the sun to enjoy good acoustic properties thus supplied?

New York City.

George Cumming.

To the Editor of GARDEN AND FOREST :

Sir.—I have three Sycamore Maples transplanted three years ago, apparently in a thriving condition except that the bark is falling off—beginning at the ground, the disease creeps up the trunk. Is there any treatment that will save the trees?

Nahant, Mass.

A. P. C.

[The spread of the disease may perhaps be checked by carefully cutting away any decayed matter which may be found where the wood has been exposed by the falling away of the bark and then covering the whole of the exposed portion with a coating of coal-tar which can be obtained from any gas works. A covering of straw wrapped loosely round the trunks to protect them from the hot summer sun will be helpful to these trees. Vigorous growth should be stimulated by cultivating at once the ground about the trees, which should then receive a good, thick top-dressing of old, well-rotted manure, which will not only enrich the ground, but will serve as a mulch and check evaporation; and next winter or in the early spring

the branches should be shortened in one or two feet all over the trees; or if they are already large more of the branches even can be cut away with advantage.—Ed.]

Nymphaea tuberosa in Eastern Waters.

To the Editor of GARDEN AND FOREST:

Sir.—Recently Mr. E. D. Sturtevant, of Bordentown, N. J., the well-known Water Lily expert, called my attention to the fact that the Water Lilies growing near my home were not the familiar *Nymphaea odorata*, but the western form, *N. tuberosa*. I have gathered a number of rhizomes and many flowers, and find that the former all have the rootstocks with compound and single, spontaneously detaching tubers, as given by Gray as characteristic of *N. tuberosa*. The flowers are much less strongly scented; some nearly inodorous and have no pinkish tinge.

Leaves, flowers and rootstock are all, as a rule, if not invariably, smaller than the dimensions given by Gray, and suggest that the plant found here bears the same relation to the true *N. tuberosa* that *N. odorata*, var. *minor*, does to the true *N. odorata*; so it might be called *N. tuberosa*, var. *parva*.

The nearest recorded locality for *N. tuberosa* is Meadville, Penn., fully 300 miles as the crow flies.

The *Nymphaea odorata* grows most luxuriantly about Morrisville, Pa., opposite Trenton, N. J., and in various localities in the neighborhood of the city mentioned. It is a curious fact, therefore, in plant distribution, that this western form should be found here in central New Jersey, and only, I believe, over a very limited area.

Charles C. Abbott.

Trenton, N. J., July 7th, 1888.

To the Editor of GARDEN AND FOREST:

Sir.—In your article on *Prunus pendula*, in No. 17 of GARDEN AND FOREST, you state that the meaning of the Japanese name *Ito sakura* is pendulous. Permit me to say that that is hardly a literal translation of it. The first syllable, *Ito*, means thread, twine, raw silk, and the like, and the word *sakura* is the name of the Cherry tree; hence *Ito sakura* would more accurately be rendered the Thread Cherry Tree—having reference to its long thin branches.

Referring to Dr. Hepburn's Dictionary of the Japanese Language I find the ordinary word for pendulous, having reference to a tree with pendulous branches, is *Shidari*, and is illustrated by the word *Shidari-yanagi*, the name of the Weeping Willow. I may also state that I sent *Prunus pendula* to Messrs. Parsons & Sons as early as 1874 or 1875, with whom it has been flowering for several years' past.

New York, July 7th.

Thos. Hogg.

Periodical Literature.

In the *Fortnightly Review* for June Mr. Oswald Crawford writes in a very charming way of "Summer Time in Rural Portugal." The picture he paints of country life in this beautiful but little known corner of Europe is an attractive one all through, but the most attractive parts of it are those which reveal the peculiarities of its gardening art. "The three summer months," writes Mr. Crawford, "are so hot, and mostly so dry, that gardening in the north of Europe fashion, with turf, and flower-beds put out therein, is possible but not easy. Perhaps it is for this reason that Portuguese gardeners are about the very worst and most ignorant in the civilized world,—knowing almost nothing of potting, and soils, and cuttings, and grafts, and forcing, and the management of 'glass,' . . . yet the gardening traditions of the Portuguese, in spite of their ignorance, are good, and much of their gardening doctrine sound. No Portuguese, either in practice or in theory, would admit, for instance, that monstrous proposition which every English gardener insists upon as a postulate too obvious for argument, namely, that a garden is a place for flowers as a turnip-field is a place for turnips. The Portuguese gardener, to judge by his results here, considers, and I think justly, that flowers are indeed very pretty adjuncts and ornaments in a garden, but of infinitely less importance than the walks, the shade of branching trees, the greenery of leaf and spray, the cooling breezes in summer, the warmth of the sun in winter, and at all seasons the golden fretwork that the sunlight makes upon the ground through overhanging boughs." As almost everything in this part of the world is a survival, Mr. Crawford explains, so are Peninsular gardens survivals of the Moorish ideal of what a garden should be, modified by the requirements of the country and climate. The ideal of the Moor in

the hot and arid lands of his nativity means as much "shade and coolness and moisture" as can be obtained,—thick bowers and vistas of foliage, plashing fountains, trickling rills, and "creeping Roses and Jasmine bushes to beget the perfume that his soul loves." In Portugal "so much shade is not wanted and the garden is more open," yet in the matter of predominant foliage as well as in many matters of arrangement and decoration, Moorish ideas are still clearly perceptible. "The Oriental delights in the intricate interlacing of flowing lines and arranges his Box edgings in elaborate arabesque patterns. Those who know Spain know the Escorial and must remember the exquisite tracery of the great Box garden there, like the gold wire rims in rich *cloisonné* enamel. Another survival of Moorish times is the wall running by the garden paths, hand high, faced with painted tiles (*azulejos*), along whose top is scooped a deep furrow filled with garden earth and planted mostly with Carnations, Pinks and Gilliflowers, or the dwarf scented purple Iris of Portugal. All these plants love the drought; and so set their flowers can be plucked or smelled to without bending the back—an ingenious device of the ease-loving Oriental."

"In such pleasaunces as these," the author continues, "as Lord Bacon says of his own ideal garden, is to be found 'the greatest refreshment to the spirits of men,' and indeed I know no other commodity of a garden whatever than to reach this end." Then he proceeds to contrast such pleasaunces at length, and with strong expressions of reprobation for the northern ideal, with "the unlovely receptacles for flowers cut out in the turf, bare earth, dreary, like new-made graves for nine months of the year, swept by the east wind in winter, burned up by the sun in summer, and in late spring the contents of green-houses turned into them to make a tawdry unharmonized display of color" which almost invariably do duty for gardens in England. "I freely confess," he adds, "that it humiliates my national pride to contemplate the pleasure gardens of my English friends; even to pass by train in summer-time through the land and see no garden that is any 'refreshment to the spirits' save those of the cottagers." It is impossible here, however, to follow Mr. Crawford through his analysis of the appearance of such gardens as rule in England (and, of course, in America as well), or of the causes which bring it about. We can only say that his words are full of instruction and pass to his concluding paragraphs, which contrast the summer-time effect of the open country in Portugal and in England. In an English June, he says, while the garden is "poor and bare and overtrim," the wood is rich and beautiful in its luxuriance. In Portugal at the same season the garden is shady and luxuriant, but the country is burned bare of all flowers save the Cistus, and almost the only trees which appear are the forests of great Stone Pines. The love for such forests, which seem at first to an Englishman dry and dreary and solemn things, grows with time; but it is always a different love from that inspired by a northern greenwood. "If the Pine forest has its charm it must be as the higher kinds of music and the subtler sorts of literature have theirs, only to him whose taste is instructed to the point of receiving the higher and subtler impressions. An English woodland . . . is charming in its way, a very 'pretty and purling stream' kind of thing; but it is as one of Strauss's waltzes to a symphony of Beethoven compared with the austere beauty of the great Pine forests of Portugal."

Recent Plant Portraits.

LISSOCHILUS GIGANTEUS, *Gardener's Chronicle*, May 19th.—A terrestrial Orchid, discovered in the Congo country by Welwitch. The peduncle of this wonderful plant is said to reach in its native country a height of sixteen feet. It bears a lax raceme of large yellow and green flowers twice the size of those of *Warrea tricolor*. In his work on "The Congo," Mr. Johnston gives some interesting particulars relating to this extraordinary plant. He says:

"In the marshy spots, down near the river shore, are masses of that splendid Orchid, *Lissochilus giganteus*, a terrestrial species that shoots up often to the height of six feet from the ground, bearing such a head of red mauve, golden, scented blossoms as scarcely any flower in the world can equal for beauty and delicacy of form. These Orchids, with their light green, spear-like leaves, and their tall swaying flower-stalks, grow in groups of forty and fifty together, often reflected in the shallow pools of stagnant water round their bases, and filling up the foreground of the high purple-green forest with a blaze of tender peach-like color."

PINUS HALEPENSIS (Catkins and Stamen), *Gardener's Chronicle*, May 19th.

ERYTHRONIUM HENDERSONII, *Gardener's Chronicle*, May 26th.—A very beautiful species recently discovered in Oregon, with pale purple flowers.

SENECIO CRUENTA, *Gardener's Chronicle*, May 26th.—An interesting figure showing the original Cineraria, with examples of its modern development at the hands of florists.

HETEROSPORUM ORNITHOGALLI, *Gardener's Chronicle*, May 26th.—One of the so-called brown moulds, closely allied to the fungus which causes cracks in Apples and Pears, which has attacked and destroyed the *Ornithogalum* in some places in England.

Notes.

An international Horticultural Exhibition will be held at Cologne from August 4th to September 19th.

Professor Count Solms-Laubach, who succeeds Du Bary in the chair of Botany at Strasburg, will in future conduct the *Botanische Zeitung*.

It is proposed to hold an International Exhibition of Botanical Geography, next year, in the city of Antwerp, similar in general scope to the exhibition of a like nature given several years ago in Copenhagen.

The American Forestry Congress and the Southern Forestry Congress will both meet in the State Capitol at Atlanta, Georgia, on the 12th of November, the former in the Hall of Representatives and the latter in the Senate Chamber.

Dr. Maxwell T. Masters, the editor of the *Gardeners' Chronicle*, and Vice-President of the Jury of Awards at the International Exhibition of Horticulture, held in Ghent in April last, has been created a Chevalier of the Order of Leopold by the King of the Belgians.

Mr. W. Y. Klee, State Inspector of Fruit Pests for California, has received a consignment of the parasites which destroy the cottony cushion scale in Australia. Experiments are in progress to ascertain whether the parasite will prove equally destructive of the scale in California, and if so, this natural foe of the scale will be cultivated with a view to hold in check the ravages of this pest of Orange groves.

Saturday, July 14th, was "Iris Day" at Horticultural Hall, Boston. The display of *Iris Kämpferi* was very fine, those shown by C. M. Atkinson, gardener to J. L. Gardner, Esq., being especially remarkable for size and variety. Edwin Fewkes & Son exhibited four seedlings in this section, which were equal to the finest imported varieties. President Wolcott showed cut blooms of hardy Larkspurs which were simply grand.

Mr. E. S. Carman has succeeded in producing several hybrids of *Rosa rugosa*, fertilized by various Hybrid Remontants and Tea Roses, and one, of which the male parent is Harrison's Yellow, was the first rose to bloom on his grounds at River Edge, New Jersey, this year, and has been in flower ever since. The flower has from thirty to thirty-five petals, which resemble in color those of General Jacqueminot. The odor is most delicate.

In the largest nurseries in France not a harrow, cultivator, plow, tree-digger or horse is to be found. The digging is all done with a spade, and the stock is delivered to the packing-yard in wheelbarrows. The ground is manured heavily, the fertilizers being carried on the backs of women, who are paid 40 cents a day of twelve hours. These facts are from an address by Mr. Irving Rouse, of Rochester, read at the late Nurserymen's Convention.

The Association of American Cemetery Superintendents will hold its next meeting in Brooklyn, N. Y., on Sept. 5th. The object of this organization is to exchange ideas on the improvement and beautifying of cemetery grounds. The officers are: President, Charles Nichols, "Fairmount," Newark, New Jersey; Vice-President, F. W. Higgins, "Woodmere," Detroit, Mich.; Treasurer, L. J. Wells, "Greenwood," Brooklyn, New York; Secretary, A. H. Sargent, "Glendale," Akron, Ohio.

One of the most attractive features of the weekly free exhibitions of the Massachusetts Horticultural Society is the display of wild flowers. Several ladies make a specialty of collecting and exhibiting these throughout the season, and as they are correctly named, the botanical name as well as common name being given, the instructive value of the exhibition is considerable. They attract as much attention from visitors as do the more showy garden flowers and exotics.

The white variety of *Platycodon grandiflorum* is now in considerable demand as a cut flower on account of its adaptability to use in formal designs. Some florists object to it because it

looks like a paper flower when on a short stem. There is a purple variety, and occasionally the flowers come part-colored. It is most effective when the spikes of both colors are set in vases, with the white kind predominating, and with a dash of scarlet to give life to the arrangement.

The Daisy-like flower of *Chrysanthemum segetum* is occasionally seen in the windows of Philadelphia florists, but not so often as it once was. It is a common wild flower in Europe, where it is sometimes called the Yellow Cornflower, the same name that is applied to *Centaurea suaveolens*. This Chrysanthemum is quite pretty when it first opens, but when left on the plant a few days the centre grows out of proportion to the outer or ray flowers. It is an annual, and when once established comes up every year, becoming in time a weed, but not a difficult one to exterminate.

At the late meeting of the California State Board of Horticulture, Mr. B. M. Lelong, the Secretary, made an interesting report on Olive culture, which has become one of the regular industries of that State, and is destined to grow largely, since the production of Olive oil can hardly be overdone. There is always a demand for pure oil; but Mr. Lelong procured in San Francisco five brands of oil, labeled Pure California Olive Oil, which were far from being pure. One contained no trace of Olive oil, and consisted of lard and Cotton-seed oil. Two others had but 10 per cent. of Olive oil. Another registered 30 per cent. Olive oil, 35 per cent. seed oils, and 35 per cent. lard, while the best sample contained more than 50 per cent. of adulterants.

In a private letter, Colonel Pearson, whose experience with the rose bug is given in another column, writes that the Black Rot appeared in Vineland on the 25th of June on varieties of Grape most subject to attack. After considerable damage, the disease seemed to subside, but appeared again July 12th. So far, the Concord has suffered worst, and one-half of them are destroyed. Ives are suffering more than usual, so are Norton's Seedling, while Moore's Early are nearly all destroyed. Of fifty varieties on his grounds, only Noah, Elvira, Conqueror and Iron-clad have entirely escaped. In the "Experiment Vineyard," up to the 16th of July, the copper-sulphate seems to have been an efficient preventive of the Grape Rot as well as the Mildew.

Whether or not plants have the power of taking nitrogen from the air is not only an interesting question, from a scientific point of view, but it is one of immediate practical bearing. If this costliest of the elements of plant food can be obtained from the air it would be of the first importance for farmers and gardeners to know what plants have this power, and under what circumstances they can exercise it. This is one of the problems to which Professor Atwater will give his attention as Director of the newly established Storrs School Experiment Station, Connecticut, as he explains in a preliminary bulletin. Professor Atwater has already paid much attention to this question, and he is inclined to believe that leguminous plants, at least, have the ability to secure a portion of their nitrogen supply from the air.

The Oak-pruner (*Stenocorus putator*) is noticed to be unusually abundant in some parts of the country. The beetle deposits its egg in the axil of a leaf stalk or small twig near the extremity of a branch of either a White or a Black Oak; the grub when hatched eats its way through the pith, up the branch for a considerable distance, and then, in order to reach the ground, cuts off the branch, which is sometimes an inch through. In order to destroy the grubs, which are capable of inflicting serious injury, the branches should be gathered up and carefully burned, or if they are not very abundant they can be cut out of the branch and killed. It is not an uncommon sight this year to see the ground under large Oak trees covered with the ends of branches six inches to three feet long. They should be gathered up daily and the grubs destroyed.

The Royal Tuscan Society of Horticulture, established in 1854, numbers nearly 700 members. It has had a marked influence in encouraging improved methods of cultivation of fruit, flowers and vegetables through its exhibitions. The Tuscan School of Pomology and Horticulture, established in 1882, is under the direction of Professor Valvassori. Its object is to train fruit and vegetable gardeners. The course of study, which is theoretical and practical, extends through three years. Boys between the ages of fourteen and seventeen are admitted, preference being given to the sons of small farmers. There are five professors, with an inspector and two gardeners, and, at the present time, thirty-two pupils. The school possesses, for purposes of practical instruction, an orchard and flower and vegetable gardens. The entrance and tuition fees are exceedingly low,

Hardy Trees for a Trying Climate.

ABRUPT transitions between extremes of heat and cold, and of dryness and humidity, render the climate of the prairies a trying one for many forms of plant life. This is especially true of fruit trees and other plants which have originated under the milder skies of western Europe or in the more equable climate of the Atlantic seaboard. During a few years past the orchards of the Northwest, planted largely with trees derived from foreign stock but which will flourish in the East, have suffered so severely as to convince fruit-growers that hardier races of trees must be planted, or their industry must be abandoned. How to secure these hardy trees is the problem upon which many active minds are now at work. The importation of varieties from climates similar to that of the prairies is being tried on a large scale. Apples, Pears, Cherries and other fruits from the central plain of Europe have been widely distributed, through the efforts of Professor Budd and others. But many close observers and experimenters advocate, as a preferable plan, the breeding up and improvement by selection of the wild fruits already found in the West, just as our most vigorous Raspberries and Grapes have been produced from native species. Perhaps both methods will prove helpful; but long and patient study will be needed before a race of trees is produced with constitutions sturdy enough to resist the severities of the climate and at the same time yielding fruits so delicate in quality as to satisfy an educated taste. The work of improving fruits and producing those adapted to any given locality will devolve largely upon nurserymen, and it must, in the main, be a labor of love, for the profits arising from study and experiment of this sort are remote enough. In the course of his admirable address at the late convention of American Nurserymen, at Detroit, Mr. C. L. Watrous, the President, dwelt upon this theme at length, and our readers will thank us for quoting this instructive extract:

The cycle of unfavorable seasons, seasons of extreme heat in summer and extreme cold in winter, which have proven so destructive to nurseries, orchards, and, in fact, to all species

of fruit-bearing trees and plants in many parts of the West, seems to have run its course, and the lessons taught by it may more than compensate for the losses. It has been observed everywhere that varieties of trees and plants indigenous to that region, or descended from such indigenous forms, have suffered least, if at all. In regions where all fruits descended from foreign ancestors have been crippled, the native forms and their derived varieties have suffered little.

Among fruits, the Apple, most important of all and wholly of foreign ancestry, has suffered most grievously, the Cherry and Plum, also of foreign ancestry, suffering the next heaviest losses. Our Grapes, east of the Rocky Mountains and outside of green-houses, being largely of native ancestry, are still ready for business or pleasure. The Raspberries, Blackberries, Strawberries and Gooseberries, all of native stock, are ready for use. Happily for the country, all these last named fruits have been so thoroughly emancipated from their taint of foreign ancestry as to be thoroughly reliable throughout all the regions indigenous to their wild relatives. It only needs that painstaking and conscientious men shall originate new and better adapted forms in every locality whose conditions render such labor necessary, and shall seek out and propagate such promising chance seedlings as may from time to time appear, in order that each botanical region may have an abundance of varieties well adapted to its needs.

Throughout all of the great empire known as the north-west, native forms of the Plum have now almost or quite supplanted the foreign stock. The Cherry and the Apple still remain to be carried through the same course of evolution, by seedling variation, that has already been passed through by the Grape, the Raspberry, the Blackberry, the Strawberry and the Gooseberry. A glance into the list of the venerable American Pomological Society will show how very few years have been spent in changing the lists of approved sorts from foreign to native names and the different native species into what now supply so large a share of the most pleasure-giving and health-sustaining part of our national diet. The same broad road to improvement is open in case of the Cherry, and especially of the Apple. At the risk of seeming extreme in this regard, I am willing to go on record before you all, as saying that I believe sufficient progress has been made to justify a confident expectation that within the lives of young men who hear my voice to-day, the common and universally propagated varieties of the Apple throughout the great north-west will be the descendants of the native Crab Apples, indigenous to the glades and thickets of the prairies, which have through ages unmeasured and immeasurable by any standard of ours, by variation and natural selection, adapted their race to every vicissitude of their climate and soil, as none of foreign ancestry ever can, except by the same measureless course of adaptation through seedling variation.

This is not all as visionary as it might appear. Already have been exhibited two different varieties of Apples bearing unmistakable proofs of legitimate descent from native thickets, which have excited favorable attention. In many different places careful and zealous experimenters are developing these, by cross fertilization and otherwise, with high hopes for the future. There is no reason why the Cherry should not tread the same king's highway towards perfect adaptation. I hold that a perfectly adapted Grape or Apple should bear its fruit, and, with proper care, be as long-lived as its wild brethren in the thicket. Why should not this be so, as well as that the civilized brain-worker should, by proper living and care, not only live as long in useful activity, but far outlive, the days allotted to the savage roaming the forests and prairies of the same region?

The considerations here urged regarding the superiority of native forms of fruit-bearing trees and plants, apply with no less force to trees and plants for ornament, shade, shelter and timber. The best authorities now agree that American trees are the best for America. The foreign trees with which so many of the older parks and pleasure grounds of the East were planted, from lack of suitable and cheap trees of our own native varieties, are steadily failing, when their days of greatest use and beauty should be just upon them. One of the most eminent authorities in America, in considering these failures, has lately said in bitterness of heart, that if these losses and failures, as lamentable and almost irremediable as they are, will only teach men the folly of proclaiming the worthiness and adaptability of any foreign tree or plant, before it has had a trial of a time extending at least through a period equal to the natural life of a single individual of the species, these losses and their lessons will not have been too dearly bought.

Every nurseryman in the nation should feel his responsibility to himself and to his generation, not only to do what he

can towards originating new and more perfectly adapted varieties of fruits and plants, but also to be on the watch for new and promising forms of chance origin, and to see that each has adequate trial and honest judgment in at least its own botanical region. After due trial and proved worthiness the promising varieties will be propagated by grafts, buds or layers, and disseminated at first in their own botanical regions, and afterwards in other regions, if found able to endure the changes. I fear the most of us have very inadequate ideas of the strain put upon the vitality of trees and plants, by transplanting them to different conditions of climate and soil. In a late most admirable report of the State Geologist of Indiana, is the statement and proofs of the fact, that there exist within the boundaries of that one state no less than seven distinct and well defined botanical regions, each marked by a preponderance of certain native plants, and the absence or scarcity of others, as shown by the lists submitted. This should be a lesson to each of our fraternity, teaching him to test the favorites of distant regions with no more than hopeful distrust, and to prove them well before proclaiming them to his friends, his customers, as worthy of confidence and the investment of money.

By allowing the glamour of a foreign name and the deceptive haze of distance to cloud their judgment, many honest men have had more prophecies to "take back" than have added to their reputations. Careful and intelligent experimentation is the daily duty of the nurseryman. The government experiment stations now provided for in every state, must be aided and largely guided by members of this fraternity in matters horticultural. The task of bringing our promising wild fruits into the realm of civilized usefulness, by change of condition, seedling selection, and cross fertilization with allied forms of native or foreign ancestry, already highly developed, may with especial fitness be vigorously pushed there. It is for our members to furnish the material for experiments and to give freely of their advice and experience as to ways and means most promising of good results. There is no reason to doubt the permanence of these experiment stations nor their generous support by the government, two considerations which entitle them to be used as the head centres of horticultural experimentation in every state, with the full and generous support and aid of every one interested in this work. The road is long, too long for individuals, but with properly directed effort, so that no steps be lost at these permanent stations, we know that the gains must be substantial and certain from year to year and from generation to generation.

The Onteora Club and its Chance for Usefulness.

A NUMBER of capitalists in this city have recently acquired possession of a tract of land more than 1,000 acres in extent occupying the slopes of the mountains near Tannersville, in one of the most picturesque and interesting regions of the Catskill country. Their object is to provide for themselves and their friends retired and pleasant sylvan homes in connection with a small hotel. There is nothing strange or unusual in this; it is what has been done a hundred times before in different parts of the country. The fact, however, that the care and development of the forest which still covers their land should form any part of a general scheme for the improvement of the property, or that the forest should be considered at all under these conditions by business men, is a matter of very considerable interest, as indicating the advance made in this country in the education of the public with regard to the forest and the part which it plays in the economy of nature. Ten years ago, a body of capitalists buying a tract of land for the purpose which has led to the formation of the Onteora Club would hardly have entertained the idea that the care and improvement of the trees which they happened to find on their purchase was a good business investment, or that such property was valuable in proportion as it was permanently covered with vigorous and healthy forests. That they now value the trees, and not only desire to preserve the forest from further encroachment, but to improve it, is a sign that the words which have been spoken in this country of late years for the forest and for forest-preservation have not been spoken quite in vain; and that at last business men can realize that there is more money in taking care of trees than there is in allowing them to be destroyed.

This is only a straw, perhaps, but it is a straw showing that the tide has turned, and that the time will come in America, as it came long ago in every other civilized country, when the value of the forest will be recognized, and the laws upon which the life of the forest depends will be clearly understood and freely obeyed. The leaders in the forest movement must not forget, however, that their task is only just begun. They may have kindled a feeble spark of interest in forest-preservation; but it is in serious danger of being extinguished, unless they can continue their work with unabated vigor and enthusiasm and with broader and more exact knowledge. They must remember, too, that it rests with them not only to teach the people of this country what forests are and what will be lost in their destruction, but that they must furnish definite instruction as to how these forests are to be preserved and developed. These are subjects upon which our people are supremely ignorant. It is easy to say the forests must be preserved; it is much less easy to explain how this is to be accomplished, or what practical measures must be applied in any particular case to produce certain results. General laws of forest management, perhaps, are not difficult to lay down, but special treatment for special cases can only be reached by experience based on experiments, carefully conducted through long periods of time. Such experiments are just what the Onteora Club and other associations are in a position to carry on, and they are what this country needs in order that systems of forest management may be devised and proved by the test of time. Such associations certainly have it in their power to perform an important public service in adding to our slender stock of exact knowledge concerning the best methods of forest management for the United States, and while doing this they can at the same time greatly increase the value of their property.

It is not easy to explain why certain plants look distinctly in place in certain situations and why other plants look as distinctly out of place in the same situations. This is a matter which nature perhaps has settled for us. It is certain at any rate that combinations of plants other than those which nature makes or adopts, inevitably possess inharmonious elements which no amount of familiarity can ever quite reconcile to the educated eye. Examples of what we wish to explain abound in all our public parks, and especially in Prospect Park in Brooklyn, where there is more of nature than in any other great park, and where along the borders of some of the natural woods and in connection with native shrubbery great masses of garden shrubs, *Diervillas*, *Philadelphus*, *Deutzias*, *Forsythias* and *Lilacs*, have been inserted. These are all beautiful plants. They never seem out of place in a garden; but the moment they are placed in contact with our wild plants growing naturally as they do, fortunately, in the Brooklyn park, they look not only out of place, but are a positive injury to the scene. It is not that their flowers are too showy or conspicuous for such positions. The flowers of some native shrubs like the *Elder*, the *Flowering Dogwood* and the *Viburnums*, are as showy as those of any garden shrub. The reason is rather that we have become accustomed to see certain plants adapted by nature to fill certain positions in combination with certain other plants in a given region; and that all attempts to force nature, so to speak, by bringing in alien elements from remote continents and climates, must inevitably produce inharmonious results. Landscape gardeners have rarely paid much attention to this subject, or sufficiently studied nature with reference to the harmonious combination of plants in the construction of scenery, and especially of scenery intended to produce upon the mind the idea of repose. Nature, nevertheless, is the great teacher to which the artist who would hope to imitate her, however crudely, must ever turn for instruction and for inspiration.

The Squares of Paris.

ONE of the best features of the park system of Paris is the number of small squares scattered about in the different quarters of the city. The parks themselves, especially the larger ones, are at such great distances from the crowded centres of population, that the working classes, except on Sundays and holidays, seldom have a chance to visit them, so that these squares admirably serve the purpose of keeping the children out of the streets, and of allowing the poorer people, in the few hours of leisure they have during the week, to get a breath of fresh air and a glimpse of green.

A stranger, on first entering one of them, marvels as he sees how neatly they are kept while so thickly crowded with visitors, reading, working or playing. In plan they are usually quite simple, as the accompanying diagram will show. A broad gravel walk, ten or twelve feet wide, following near but separated from the boundary by occasional shrubbery plantations, encloses a quiet piece of lawn sufficiently open to get a glimpse through to the opposite end, but planted on the sides with trees, shrubs and foliage plants.

Plan of a Paris Square.

There are few attempts at fancy gardening, but much care has been taken to select hardy shrubs and plants with the view of avoiding bare and empty beds during the winter. The condition of the turf is everywhere excellent, for water is freely used, and suitable small playgrounds are provided for the children, which serve the purpose of keeping them off the grass. These playgrounds, which are an admirable feature, are generally formed by simply widening the walks in the corners and planting enough trees there to afford ample shade. There are always one or two flower beds, which are kept bright and attractive during the spring and summer by a constant succession of showy flowering and foliage plants. Permanent seats are provided, but not in sufficient numbers to accommodate every one, but for a very small sum a chair for the whole morning or afternoon can be hired and you can move it about at will.

The only serious fault in all these squares is the stiff and formal appearance of the shrubberies. Almost without exception these plantations are in the form of regular figures—circles, ovals or ellipses—and they are always planted on slight mounds. These two facts detract very much from any effect of naturalness, and it seems a great pity that, when it is so easy to give a varying outline to the groups, it has not been done. It would also be an improvement to plant the borders of these beds with plants or shrubs of low, half trailing habit, and thus, in a measure, hide the sharp, stiff outline between the turf and the dug ground of the bed.

Of course, there are many variations from the typical plan. The Square des Batignolles contains about three acres and is one of the largest in Paris. It is situated on sloping ground, with an open lawn in the centre, through which runs a small winding stream, which broadens out into an almost circular pond at the lower end. The course of this stream, in order to make a little variety, is occasionally interrupted by a group of

rocks, which cause it to widen out into small pools, the margins of which are attractively planted with aquatic plants.

The Square des Arts-et-Métiers is on quite a different plan. Here a broad walk runs down the middle, giving a fine view of the building at the further end. It is surrounded by a handsome stone balustrade, and following this, on the inside is a strip of turf and shrubbery about eight feet wide. All the rest of the surface, with the exception of two fountain-basins, is of gravel, and is thoroughly shaded by eight rows of large Horse-Chestnuts, whose branches touch each other, and thus form a very dense shade over the whole. Seats are provided here in plenty, and as it is one of the most crowded parts of the city, it is always full of people.

The Square du Temple is one of the prettiest of all the Paris squares, or would be if the attempt had not been made to adorn it with statues. There are four of them here, and they detract much from the quiet and repose of the place. At the upper end there is a small cascade falling over artificial rockwork into a rather too formal pond. The trees in this square are exceptionally good.

These are a few of the more important squares, but by no means all, for in Paris there are no less than seventy breathing places, not counting the boulevards and other tree-planted streets. They are usually most attractive spots and teach a lesson which might very well be copied in many of the crowded cities of our country.

Paris.

Henry S. Codman.

Foreign Correspondence.

London Letter.

AMONG the plants certificated at the last meeting of the Royal Horticultural Society, the greatest novelty, in my opinion, was the Japanese shrub, *Cesalpinia Japonica*, shown by Messrs. Veitch, and which has proved quite hardy in Coombe Wood unprotected. It has leaves about a foot long, divided into small pinnæ, like a Mimosa and very elegant. The flower spikes are borne at the tips of the shoots, and are erect, about eight inches high, carrying numerous flowers in a loose way. They are about an inch across and of a brilliant yellow. The whole spike so closely resembles that of one of the Casias (*C. arctura*) that one could scarcely tell the difference without close inspection. The flowers are so showy and the foliage so elegant that the committee were unanimous in awarding a first-class certificate, and every one looks upon it as a valuable addition to hardy shrubs. Another first rate, hardy, Japanese shrub, with evergreen foliage, from Messrs. Veitch, was certificated. This was *Daphniphyllum glaucescens*. It has a dense, bushy growth (about three feet in height in the plant shown), with leaves reminding one of *Rhododendron Catawbiense*, but larger and thicker. They are pale green above, and of a glaucous hue beneath. The specimen shown was not in flower, but there are flowering plants of it at the Coombe Wood nursery. The berries are said to be ornamental, but I have neither seen flowers nor fruit. I have seen the plant for some years past growing in exposed places, and believe it will prove a valuable evergreen shrub here, and probably it may be hardy on the coast and in warm districts of the United States.

A graceful variety of the grass *Eulalia Japonica* likewise came from Messrs. Veitch, and received a certificate. It is named *gracillima*, and most appropriately. The leaves are very long, not more than one-sixth of an inch broad, and elegantly recurve on all sides. The mid-rib is white, as in the variety *univittata*, though, perhaps, not so pronounced. There was but one opinion among the committee, and this was that the new grass was a real acquisition.

Only one Orchid received a certificate (a fact worthy of note), and this was the new *Epidendrum atropurpureum*

Randii, or, as some of your readers may prefer to call it by its synonym, *E. macrochilum Randii*. It is one of the evergreen Epidendrums, with egg-shaped bulbs and stiff, narrow leaves, and a densely-flowered, erect spike. The flower, about 1½ inches across, has olive green sepals and petals, and a broad, wedge-shaped lip, pure white, with carmine blotch in the centre. The perfume is delicious, and another good point in it is that the flowers endure a very long time, several weeks, in fact, if kept cool and in a dryish house. There is not such a great difference between the old *E. macrochilum*, pure and simple, and the new one, but the latter seems much freer in growth and flower. It was shown by Sir Trevor Lawrence, who also showed, besides other choice Orchids, a marvelous specimen of *Dendrobium Bensoniae*. It consisted of about a dozen pseudo-bulbs, each fifteen inches high or more, and every one was densely covered with bloom. But alas! it was an imported plant, and never again will the bulbs put out such a wealth of bloom.

An addition to the numerous race of green-house Rhododendrons has been made by Messrs. Veitch, who have done more in the improvement of this race of shrubs than any one else. They first intercrossed the Malayan *R. multicolor Curtisii*, a small flowered species of dwarf, straggly growth, with another species named *R. Teysmannii*, which has large, bold, pale yellow flowers, the result being a variety called Queen of Yellows. They have again crossed this with *R. Curtisii*, and obtained a splendid novelty called Hippolyta, which is quite a "break" as regards color. The value of *R. Curtisii* lies in its rich carmine crimson colored flowers and this tint has been infused in the cross with Queen of Yellows. The flowers of Hippolyta are of beautiful shape and of a color as rich as those of its parent. We shall have to wait a few years before we can realize what this superb race of Rhododendrons will be; we want to see them on specimens a yard across. I saw some of the older sorts not long since in Fisher's nursery at Handsworth, where these Rhododendrons are grown to perfection.

The display of fancy Pelargoniums was remarkable and the peonies of Messrs. Kelway of Langport still more so. Two thousand blooms were shown, many of them as large as a child's head, of richest color, and a fragrance rivaling that of a Tea Rose. But one new Rose was shown, a beautiful single flowered one, sent by the Rev. H. Dombrain under the name of Striped Briar. The flowers are as large as those of *Rosa canina* (Dog Rose), of a deep and pleasing rose-pink with splashes and flakes (not stripes) of white, while the foliage was scented like that of the Sweet Briar. But the experts said that it was not a variety of the Sweet Briar (*R. rubiginosa*), while others thought it was, so it was decided to send the specimens for identification to Kew. Everybody at the meeting was charmed with it.

London, July 2d.

W. Goldring.

New or Little Known Plants.

Magnolia Thompsoniana ×.

THE interesting and handsome Magnolia figured upon page 269 of the present issue originated, according to Loudon, in the nursery of a Mr. Thompson, at Mile End, in England, eighty years ago. There are colored figures of this plant in the *Botanical Magazine* (t. 2164), in Hilaire's "Flore et Pomone Francaises," v., t. 451, in Reichenbach's *Exotic Flora*, t. 342, and in the "Sertum Botanicum," v., t. 28; but none of these are good or do justice to its beauty. It has been considered a large flowered variety of *M. glauca* (var. *major*, *Botanical Magazine*, l. c.), and by some authors a hybrid between *M. glauca* and *M. Umbrella*. It is probable that the latter supposition is correct, as, although the leaves of *M. Thompsoniana* cannot be distinguished from those produced on a vigorous plant of *M. glauca*, the leaf buds are quite glabrous and destitute of the silky hairs which cover those of that species, while the

broad, strap-shaped, reflexed sepals, and obovate-oblong petals, contracted into a narrow claw, distinctly belong to *M. Umbrella*; the flowers, rather more than six inches across when fully expanded, being intermediate in size between those of the two species. They have, on the other hand, the delicious fragrance peculiar to the flowers of *M. glauca*. So far as I know, *M. Thompsoniana* does not produce fruit; and it is a curious fact that it is much less hardy and much less vigorous than either of its supposed parents, suffering here always, unless carefully protected in winter, and rarely rising above the size of a small bush, although Loudon, in his "Arboretum," published in 1838, speaks of trees at Mile End more than twenty feet high. I shall be glad to see fruit of this plant and to learn if it grows more vigorously in Europe than it does in this country. Our illustration is from a drawing made by Mr. C. E. Faxon of a flower from Mr. Parkman's garden in Jamaica Plain. It shows the three sepals reflexed before the full expansion of the petals.

Herbs for Seasoning.

MINT, Sage, Thyme, Parsley, Chervil, Savory, Tarragon, Basil, Marjoram, Chives and Shallots are the herbs most generally used in the kitchen, but in books and catalogues a number of others, Clary, Samphire and the like, are included, though they are very seldom used. Some of these herbs—Parsley, Mint and Chives, for instance—are indispensable in the smallest cottage gardens, and nearly all are grown and called for in large private gardens. But apart from their utility as herbs used as seasoning, most of them—say Sage, Thyme, Sweet Basil, Marjoram and Winter Savory—are favorite garden plants, and are grown, like the Sage for its pretty flowers in June, and the Thyme for its fragrance at all times.

Spear Mint is a hardy perennial easily grown in any good moist garden soil. If increase is wanted dig up a clump and divide it and replant. The same plantation will last for years. In order to have green Mint early in the year lift some roots in November, plant them in shallow boxes and in January or February bring these into the green-house; or plant a few clumps in a warm frame.

Sage is a hardy perennial easily raised from seed sown in spring. The same plants are good for many years, but in order to have vigorous stock it is well to renew them every few years, and for this may be used some of the many self-sown seedlings that come up every spring about the old plants.

Lemon Thyme is a very sweet herb, a hardy perennial, easily raised from seed sown in spring, and lasts for years; but it is well to renew it every second or third year. The broad-leaved English and sand Thymes are not as good for flavoring as the Lemon Thyme.

Curled-leaved Chervil is a short lived annual very much used by French cooks. It should be sown two or three times a year, and in some part of the garden where it may be allowed to sow itself, as it always grows better in this way than when hand sown. Seeds over a year old will not germinate. That sown in fall survives the winter perfectly.

Sweet Basil is a fragrant annual, easily raised, but only occasionally called for; indeed it is worth more as a sweet-smelling ornamental plant than for use in the kitchen. Sweet Marjoram is a slender growing annual, but easily raised from seed. It is used a good deal, and more esteemed for flavoring than Pot Marjoram, which is a hardy perennial, and a small, neat growing plant, but not very hardy.

Summer Savory is an annual of slender growth, but easily grown in light rich land. Winter Savory is a small plant, a perennial, and not hardy here, but raised from seed sown in spring it soon forms neat little plants. The Summer Savory is the one most esteemed for flavoring. Tarragon is a hardy perennial and much used by English and French cooks. It is a vigorous growing plant, spreading at the root a good deal and loving rich soil. Although the clumps will last for years, it is best to lift, divide and replant them every second or third year, to invigorate and keep them within bounds.

Although the plain leaved Parsley is the best flavored, there is, so little difference between this and the curled-leaved varieties, that most persons prefer the Moss Curled, on account of its pretty appearance in garnishing. Celery is useful all the year round. So long as blanched Celery is on hand

Fig. 43.—*Magnolia Thompsoniana* X.—See page 268.

—from September till first of May—that will do, but during the summer season a supply of young plants must be maintained to furnish green leaves for flavoring.

Chives are very hardy and easily grown and multiply exceedingly. They are the earliest of our garden plants to start to grow. Lift, divide and replant them at least every second year. A few clumps will suffice. For winter use lift a few in the fall, plant them in shallow boxes and bring them indoors. Shallots especially with French cooks, are more esteemed than any other member of the Onion Family; they use the small pear-shaped bulbs—or cloves, as they are usually called—

whole. Planted in spring in rows fifteen inches apart, four or five inches apart in the rows, and three inches deep, in rich ground, they grow and increase very satisfactorily here. They are kept over winter like Onions. While some or most of these herbs should be grown in all well-regulated gardens, a few plants—Parsley, Celery and Shallots excepted—of a kind are enough. And in order to have them for use in winter or at any other time when not growing green in the garden, a part should be gathered and dried. Just as they are coming into flower is the best time to cut them, then tie the plants into small bundles and hang them up to dry. *W. Falconer.*

Strawberry Notes.

THE Strawberry season of 1888 came far short of fulfilling its early promises in this region. The season opened about two weeks later than the average, as our first picking of any account occurred on the 15th of June, though the berries began to color on the 10th, and the last picking was made only a week later than usual. With few exceptions the crop was light. Probably the peculiarity of the season had much to do with this, but the chief cause in my own case was the brown rust, which rendered some varieties absolutely worthless. Some years ago I fancied that certain weather conditions favored the development of this fungus, but it appeared this season under conditions directly opposed to those heretofore considered favorable for its growth.

I am inclined to think now that the young blood of new varieties of vigorous habits is for a time less liable to suffer from this cause than our older sorts. But this is by no means certain, and the subject is one well worthy of study and investigation at the Experiment Stations. If there is any remedy to prevent the ravages of this disease it is one that I have never tried. Aside from the damaging effect this fungus had on the quality of the fruit, it seemed that berries generally of all varieties, even from healthy plants, fell short of reaching their highest quality, and this view was corroborated by the opinion of many others.

Prince, Jersey Queen, Sharpless, Manchester and Crescent are still standard sorts, and the latter, for vigor, health and productiveness, can be depended upon. Manchester seems more and more inclined to rust. Among the newer varieties the Davis is so nearly a reproduced Sharpless, that no one could separate plants or fruit if put together. Jewell, so large and attractive, shows such a tendency to rust on my grounds that I shall have to give it up. May King has proved vigorous, healthy and productive, a bright, attractive berry of good size and fair quality. Belmont, large, showy and of good quality, but like the Sharpless, not an abundant cropper. Henderson and Cornelia are not of much account, either in growth or in productiveness. Cohansey must be abandoned as worthless after two years' trial. Whatever it may do elsewhere, in this part of New Jersey it refused to make a respectable growth.

Among varieties fruiting the first time this season is the Jessie, which is promising, and, so far, healthy. The berries are of fair size under ordinary culture, and the quality is good; perhaps further trial may prove it very good. As I only saved about twenty per cent. of the plants set last season, I had but a limited show of fruit. I think it will do to plant more of it. Another one fruiting here for the first time is the Pearl, which is as promising in all respects as the Jessie. The berries were quite as large and handsome, with a general tendency to a reflexed calyx, a feature I always admire—and in quality it does not suffer in comparison with the more highly extolled and widely known Jessie.

At the exhibition of the American Institute Farmers' Club, on the 21st of June, Mr. H. H. Alley, of Hilton, N. J., made a fine show of a dozen seedlings of prodigious size and bearing qualities, conspicuous among which was one named Hilton, which the judges endorsed as "very large and firm; color, scarlet; good shape; sub-acid; good flavor; said to be a great bearer." Mr. J. J. Davis, of Washington, N. J., also exhibited five of his seedlings, remarkable for size and appearance. Those numbered 10 and 20, very dark crimson, were preferred by the raiser. Both had been ripe for two weeks, but the judges thought his No. 25 the best, of which they report as follows: "A very firm berry; color, very bright scarlet; quality, good; flesh very firm and solid; very promising." E. Williams.

Montclair, N. J.

Some Floral Novelties.

Salvia prunelloides, from the Jorullo Mountain, Mexico, used to be grown in our gardens years ago; then it became lost to cultivation, and has only this year been re-introduced to general cultivation. It is a small-growing, perennial species, tender here, but it can be enjoyed in perfection if treated as an annual. It has small, pale green leaves, and small, bluish-purple flowers. It is not striking or beautiful enough to become a favorite in gardens, and, probably, it will soon drop into oblivion again.

Torenia Fournieri, var. *White Wings*.—*Torenia Fournieri* is now a familiar annual in gardens and well worthy of cultivation. It forms neat bushy plants, eight to ten inches high, which are covered with pretty violet-blue flowers all summer long. In *White Wings* we have the exact counterpart of the

species, except that instead of being violet-blue, the flowers are white. It comes true from seed. While it is a distinct and desirable variety, of the two, judging them as they are growing and flowering here side by side, the blue one seems preferable.

Salvia coccinea is an old and common inmate of gardens, and is, most always, treated as an annual. The typical form grows four feet, often five feet high, and, unless staked, its wand-like branches are apt to break down by their own weight. But the dwarf variety known as var. *pumila*, about half the height of the old form, is a comely plant and the one now usually grown. A new variety, with pure white instead of scarlet flowers, and known as var. *lactea*, has now been sent out. We find it of medium size, and just as free a grower and bloomer as the old scarlet flowered varieties. But, except for variety's sake, neither the scarlet nor the white forms are desirable enough for small gardens; among scarlet *Salvias* *S. splendens* still remains the most useful sort.

Zinnia linariis is a pretty little species from Mexico now in bloom with us. It is of dwarf, bushy habit, has slender, narrow leaves, and bright golden-yellow flowers, and, like nearly all *Zinnias*, seems to be a free flowering plant. Its flowers remind one of those of *Z. Haageana*. But in its present condition it is not likely to become a popular garden plant. Sent out this year.

Glen Cove.

W. F.

Single Pæonies.

THE Pæonies have been exhibited in excellent condition at the metropolitan flower shows this year, the double varieties of *P. albiflora* being numerous and very good, and the colors of the most varied kinds. Some of them are deep purple, purple-crimson, crimson, pink, delicate rose, bluish white, etc. Amongst them the single forms of this species were very attractive to the visitors. They were distinct in character from the double varieties, and are certainly more elegant.

The many species now in cultivation in our gardens form a noble and distinct feature in May. We grow thirty-three species and varieties of species, but this being a rather late season they were not fully in flower until the last week in May. Although not much known at present in English gardens, they were cultivated many years ago, and some of the prettiest of them have been longest known.

P. tenuifolia is a very elegant plant with finely divided leaves, distinct from any other. The large crimson flowers with yellow stamens are very striking. It is figured in the *Botanical Magazine* (tab. 926), where it is stated to grow "naturally in the Ukraine and about the precipices on the borders of the Volga," etc. The first to flower with us was *P. peregrina*, another crimson-flowered Levantine species with large bold leaves, but not so striking as those of some kinds. It was cultivated by Miller, and also by Mr. Salisbury at Brompton. The next to open its flowers was *P. decora*, not the most handsome species, but the flowers were a distinct purplish rose. The downy leaves of *P. mollis* are distinct from those of any other Pæony; the flowers deep purplish red; anthers bright yellow. *P. aretina* and *P. aretina Baxteri* are two good sorts; the first has rosy crimson flowers, and the variety *Baxteri* crimson; they flowered about the same time. The common *P. officinalis* in its single state was very pretty, the flowers being of a rosy tint, the petals rather crumpled. This plant was cultivated in England as long ago as 1548. In Parkinson's time single and double forms were cultivated. The variety *anemonæflora* flowered with us also. In this variety the flowers are purplish crimson, and the yellow stamens are replaced by numerous purplish filaments. Both are figured in the *Botanical Magazine*, the latter at tab. 3175. The plant had been sent from a certain Prince de Salm Dyck about 1830. *P. anomala* came next in order; the flowers crimson, set off by lanceolate leaves. It is not very striking as a garden plant, but interesting as a distinct form. It is figured in the *Botanical Magazine* (tab. 1754), where it is termed the jagged-leaved Siberian Pæony. It is stated to perish in our gardens in winter, not from cold, but from wet. In our garden it stands well enough. *P. Emodi* was next in order; it has large cream-colored flowers with golden anthers. It is also a *Botanical Magazine* plant, figured in 1868 from a plant grown at Glasnevin by Dr. Moore. It is said to be more tender than any other species, being a temperate Himalayan plant from Kumaon to Cashmere. *P. triternata* has flowers of good form, rose-colored. This is distinct both in leaf and flower. *P. peregrina compacta* and *Byzantina* also flowered with this group, and are distinct from the species. All the above flowered the last

week in May and up to the 6th of June, when the following were noted: *P. humilis*, a dwarf species with rosy purple flowers and yellow stamens, the plant dwarf and compact; *P. Wittmanniana*, creamy white, very distinct. This is supposed to have yellow flowers, and was introduced so long ago as 1842. It was discovered by a certain Count Woronzoff in Abeharia, as stated in the *Botanical Magazine*, where it was recently figured. Dr. Lindley also stated that 25 guineas were demanded for a plant of it. *P. Broteri* had rich crimson flowers with yellow anthers, the plant dwarf and distinct. *P. Brownii* is very distinct; it is planted in the rock-garden, and is a neat-habited little plant, but so far we have failed to flower it. *P. Russi* had well formed crimson flowers, with a mass of bright yellow anthers; the leaf and plant distinct. The true *P. albiflora* and varieties *laciniata* and *rubescens* flowered freely, and are the most beautiful amongst the single Pæonies.

They are all very easily grown, and I do not care to coddle them up in pots; even the little *P. Brownii* takes its chance out-of-doors. The border where they are growing has been deeply trenched and well manured. Some decayed manure was also placed on the surface during the winter, but even this is not necessary, as they seem to be all perfectly hardy. They need only to be left alone and will in time grow into large specimens, and the distinct foliage as well as the flowers look well amongst those of other herbaceous plants in a mixed border.
J. Douglas in the London Garden.

Cœlogyne Dayana.—This is a very handsome Orchid, with inflorescence much in the way of *C. Massangeana*, but it differs in the growth in having long, narrow, pyriform bulbs, bearing two oblong, acuminate leaves. The racemes are pendulous, sometimes three feet long and many-flowered; a plant in flower with us now has eighty-four flowers on three racemes; as seen in this condition it forms a particularly attractive object. The flowers, about two inches across, are of a light ochre yellow, while the lip, of the same color, is curiously marked with dark brown. It is a recent introduction from Borneo, and is named in honor of the late Mr. Day, a great lover of this class of plants. This species requires very liberal treatment during the growing season, and to insure good spikes of bloom, it should have a thorough rest, by reducing the water supply to a minimum.

Zygopetalum (Promenæa) citrinum, a charming little Orchid, growing in a compact mass three to four inches high, both leaves and bulbs being of a grayish-green color. The drooping scapes bear a single flower of rich yellow, with a blotch of crimson in the front. This is a species that is not often seen in collections, and yet it will well repay cultivation, being extremely free flowering, and taking up so little room. It grows freely in the Odontoglossum house in equal parts of peat and moss, baskets being preferable to pots. It was introduced about fifty years ago from Brazil.

Cattleya Gaskelliana.—Numerous examples of this fine species are now in flower, and we find it very valuable for filling up the gap between the flowering of *C. Trianae* and *C. Eldorado*, as it is much freer to bloom than *C. Gigas*, which is in season now. It is undoubtedly only a geographical form of *C. Warneri*, which it closely resembles, though there is a great variation in the color of the flowers. They are usually of a pale amethyst, with a deep purple blotch on the front lobe of the lip. The form with white flowers is very rare. This species was introduced from Venezuela about five years since. *Cattleya speciosissima*, also from the same locality, is now in flower, and though not as large and showy as its congener, it is very attractive and exceedingly welcome at this dull season.
F. Goldring.

Kenwood, New York.

The Rock-Garden.—It too often happens that gardeners leave the filling up of vacancies in the rock-garden until after the bedding season is over and then plant in what odds and ends are left. This seems to show a lack of interest in a department of gardening which deserves careful attention, if attempted at all. In summer-time plants in the open air are far more appreciated than those under glass. We see bedding plants all the winter in the green-house and all summer in the flower-garden proper, and, to say the least, the rock-garden should be kept as natural as possible by planting only what is appropriate. The best thing to do in the above case is to grow a few showy, dwarf annuals, and fill them in as vacancies occur. The following are useful for this purpose: *Zinnia Haageana*, *Nierembergia gracilis*, *Statice Suworowi*, *Phacelia campanularia*, *Ionopsidium acaule* and *Limnanthes Douglasii*. The latter plant can be had in bloom very early in spring by sowing in August or September, and is often used for

spring bedding. All the above may be raised in heat, or in the open border after the 1st of May. The list might be supplemented considerably, but these we find sufficient for our purpose.
T. D. Hatfield.

[The introduction of bedding plants like Scarlet Geranium or Coleus into the rock-garden for summer decoration is not more inappropriate than the use of showy flowered border annuals for the same purpose. Plants of either of these classes cannot fail to produce inharmonious and therefore displeasing and unsatisfactory effects in connection with the proper inhabitants of the rock-garden, which by a judicious selection of hardy plants and by the free use of hardy Ferns can be made attractive and interesting throughout the season.—Ed.]

A Good Rose.—Among the comparatively recent additions to the list of useful Roses, "Papa Gontier" seems to be growing in favor on account of its many good qualities. Some fault has been found with it, because of its having lost too much of its lower foliage during the latter part of the winter, so as to render the plants rather unsightly. But though this feature has been noticed in a number of cases, yet it has not been proved to be a characteristic of the variety, because there are many exceptions to the rule. In some instances it is quite possible that the plants may have been overwatered, or perhaps they may have been kept too warm; either of which would be likely to produce such a result. However, the fact remains, that Papa Gontier will be largely planted during the present season, and will also be much used for summer-flowering, both out-of-doors and under glass. The flowers are not only much larger, but have much more substance than the old and popular Bon Silene.

This subject of summer flowering suggests the reminder that one who wishes to cut Roses of fair quality during the summer months, must give his plants attention at the proper time, and not allow the weeds as well as the Roses to take care of themselves after he lets out his fires in the spring. Extremes of temperature should be avoided in summer as in winter, and thorough, though careful ventilation, and plenty of water, should be given in bright weather, if mildew is to be avoided.
W.

Weeds.—At this season of the year the principal and most important operation in the garden is the destruction of weeds. Labor and money will be saved if all surfaces of exposed soil are stirred so frequently that the germinating seeds of weeds are killed before the plants appear above ground. It is hard to realize this always, or to command labor enough in a large garden to make it always practicable, still it is the only economical way in which to deal with weeds. In the case of Purslane, for example, if the plants are allowed to grow large enough to make any appearance above ground, they have to be hoed or pulled up and then raked into piles and carried away and burned or buried deep, or they will root again after the first shower, and the work will have to be done over again. The Purslane, the Shepherd's Purse, the Chickweed, and some other weeds, flower and ripen their seed in a surprisingly short time after they appear, and if the gardener allows them to get any start of him his land will soon get full of their seeds, which will live for a long time under ground and germinate as soon as cultivation brings them near enough to the surface. Theoretically, there never should be a weed of any kind in a garden, but in this climate of hot suns and frequent rains there will always be more or less of them. They should not be fed, however, to pigs, as is often done, as the seeds then get into the manure pile and so increase the work of succeeding years. In large gardens vegetables should, wherever possible, be planted in rows, so that labor may be saved in cultivating them and in destroying the weeds by the use of horse power.

Armeria vulgaris is an old-fashioned garden plant which thrives in almost any soil or situation, but succeeds best on a moist subsoil. It is so common in some parts of England that it is used as an edging for walks in the same way as the lovely *Gentiana acaulis* is used in Scotland. There are several beautiful varieties and all make capital rock plants. The colors vary from white to pale rose and rosy purple. *A. dianthoides*, *A. juncea* and others are classed as specifically distinct, but when grown side by side, raised seedlings of each show every conceivable intermediate form, with regard to habit and color of flower. They must be propagated by division if the types are to be kept constant.
T. D. H.

Plant Notes.

The Double-Flowered Chinese Crab Apple.

OUR illustration represents a flowering branch of this ornamental tree, the *Pyrus spectabilis* of Aiton, a native of northern China and an old inhabitant of gardens, although now less often planted in this country than some of the forms of *Pyrus baccata*, especially those of Japanese-garden origin, of which one of the most useful was figured in an earlier issue of this journal (6), and from which *Pyrus spectabilis* may be distinguished by its persistent calyx lobes, which remain upon the fruit until it decays.

The Chinese Crab Apple, as seen in gardens, is a small shrub-like tree, twenty to twenty-five feet high, with rigid, upright, light gray branches, oval-oblong, finely serrate, leathery leaves, dark green above, paler on the under sur-

Loudon's remark of the Chinese Apple that "no garden, whether large or small, ought to be without this tree," still holds good, notwithstanding all the introductions of the last half century.

C. S. S.

Notes from the Arnold Arboretum.

Genista tinctoria, the Woad Wax, is a dwarf European shrub, one to two feet high, with creeping root-stalks, and upright branches, clothed with dark green, simple leaves, and now terminated with spicate racemes of handsome yellow flowers. It is a plant of no little beauty, very tenacious of life, and capable of spreading rapidly, under favorable conditions, over large areas. In some parts of Essex County, in this State, it has become thoroughly naturalized, and has taken possession of thousands of acres of rocky upland, from which it is practically impossible to exterminate it, and which is thus ruined for pasturage or for tillage. These hills, when the Woad Wax is in flower, seem to have been covered with a

Fig. 44.—The Double-flowered Chinese Crab Apple.

face, which, as well as the petioles and young shoots, is covered, especially along the mid-rib, with a short, fine tomentum. The flowers are semi-double, nearly an inch across when expanded, pale rose colored, fading white, and much lighter colored than the large, showy, bright red flower-buds. They appear here the middle of May, and are produced with the greatest profusion along the entire length of the branches in sessile, many-flowered umbels. The fruit, which rarely sets here, barely exceeds half an inch in diameter; it is round and somewhat angled, or often oblong, and when fully ripe of a dull yellow color, and hardly edible. The Chinese Crab is propagated by grafting on the common Apple tree. There are excellent colored figures of this plant in the *Nouveau Duhamel* (vi., t. 42, f. 2) and in Watson's "*Dendrologia Britannica* (i., t. 50, the flower with the normal number of petals).

golden carpet, and present an appearance quite unlike anything which can be seen in any other part of the United States. There is a tradition that the Woad Wax was introduced into the United States by Governor John Endicott, of Salem, who planted the famous Pear tree which still bears his name, and one of the pioneers of American horticulture, whose garden and farm were well known in the colony before the middle of the seventeenth century. There is, I believe, no other instance in the United States where a foreign shrub has taken such complete possession of so large an area, or has so entirely driven out the natural occupants of the soil. All parts of this plant, especially the leaves and branches, have been used in Europe by dyers to produce a yellow color, although it does not appear to have been cultivated for this purpose, and it was probably the beauty of the flowers which gained for it a place in Governor Endicott's garden, and so led to the ruin of the Essex hills. A variety of this plant, with taller and more slender stems, and

which does not bloom until several days later, is the var. *Sibirica*, once considered a distinct species. This variety, according to Loudon ("Arboretum," ii. 584), attains, in its native country, a height of five or six feet. Here it barely exceeds two feet. Two plants grown in the Arboretum as *G. lata* (*elata*?) and *G. dumatorum* are clearly the same as the Siberian variety. Some attention has been given of late years to the Woad Wax by planters wishing to cover exposed or sterile ground with a low, hardy, fast-spreading under-shrub. It is well suited for this purpose, but care should be taken that it is not planted in situations whence it can overrun and take possession of valuable land, as it will prove a difficult weed to exterminate when once it has fairly established itself.

Cytisus nigricans is one of the most desirable of the dwarf, yellow-flowered, hardy shrubs of the Pea Family, which blooms at this period of the year. It reaches here a height of a couple of feet, with erect, slender, twiggy branches, delicate leaves with three leaflets, pubescent on the under surface, as are the young shoots, calyxes and pods, and elongated, slender, terminal, erect racemes of bright flowers. The whole plant turns black in drying, a fact to which it owes its specific name. It is a native of central Europe, and has been cultivated on account of its beauty for more than a century and a half, although rarely seen in American gardens. *Cytisus capitatus* is in bloom at the same time. A less graceful plant than the last, it is not without its value. Its habit is compact and good, the flowers, in dense, terminal heads, are showy, and it remains in bloom during several weeks. The erect branches, two feet tall, are hispid, like the broad leaflets. It is a native of the mountainous parts of southern Europe and has long been known in gardens.

Free-growing, twining plants, perfectly hardy in this climate, are not very abundant; the introduction, therefore, of a plant of this character of the first class, like *Actinidia polygama*, is a matter of some importance. *Actinidia* (from *aktin*, a ray, the styles radiating like the spokes of a wheel) is a genus of Asiatic plants, many of them twining, of the *Ternstramiaceæ* or *Camellia* Family, of which *Gordonia* and *Stuartia*, two genera of woody plants found in the Southern States, are the North American representatives. They have simple deciduous leaves, axillary clusters of white, fragrant flowers, and a fleshy fruit composed of the coalescing carpels. Five or six species are described. Several Japanese species or varieties are cultivated in the Arboretum, but none of them except *A. polygama* have been sufficiently tested yet to warrant any statement of their merits. *A. polygama* is a strong-growing, vigorous plant, which in good soil will soon reach a height of twenty feet or more, and cover a large space with its vigorous branches, which are densely clothed with handsome, dark green, coriaceous, broadly-acuminate leaves, three or four inches long, with sharp, slender, remote teeth, and contracted into a long, slender point. With the exception of a few hairs on the under side of the mid-rib, they are quite glabrous, and are borne on stout, bright red petioles half their length. The white, fragrant flowers, half an inch across, make but little show, being almost concealed in the abundant foliage. The fruit, which has ripened in several gardens in different parts of Massachusetts, is as large as a pigeon's egg. It is edible and has an agreeable flavor; and is said to be esteemed by the Japanese. The *Actinidia*, however, will be cultivated in this country for its bold habit and handsome foliage rather than for its fruit.

Although they produce far less showy and conspicuous flowers than their Asiatic congeners, the two North American species of *Diervilla* or Bush Honeysuckle, are worth growing, especially in wild parts of the garden. *D. trifida* is a common northern shrub, found from Newfoundland to the Saskatchewan, and extending through the Northern States to Kentucky and the Alleghany Mountains. It often forms dense, low masses of shrubbery on the borders of the forest. It has ovate-oblong, petioled leaves, and axillary peduncles, bearing three small flowers, with narrow, funnelformed, yellow corollas. *D. sessilifolia* (the *D. splendens* of many foreign collections) is a handsomer plant, with sessile leaves, and many-flowered cymes of larger and more showy yellow flowers. It is much more rare and much less widely distributed than the first species, being confined to a few localities on the high mountains of North Carolina and Tennessee, where it inhabits rocky woods and banks.

Few ornaments of the garden are more beautiful or more satisfactory than the old-fashioned twining Dutch Monthly Honeysuckle, once common on every cottage porch, but now, for some reason, greatly neglected and rarely seen in this country. It is a variety of the common European Honeysuckle or

Woodbine of England (*Lonicera Periclymenum*), which some authors call the var. *Belgicum*. It has smooth, purplish branches, oblong-oval leaves, dark green and shining above, and pale on the lower surface. The deliciously fragrant flowers, in terminal heads, are reddish or purple on the outside and yellow within. This plant is perfectly hardy, and remains in flower nearly all summer.

Cornus asperifolia is in bloom. It is a western and southern species, with the habit and general appearance of *C. stonolifera*, but the branches are brown instead of red, and roughly pubescent, as are the leaves on their upper surface. This is a tall, hardy species, but not better in any particular for general planting than our common Eastern Dogwoods of the same class.

A Japanese Bramble (*Rubus trifidus*) is worth a place in the garden on account of the rose colored petals, which make the flower-clusters showy at this season of the year. It is a robust, vigorous plant, with semi-erect stems, clothed with ample, deeply divided leaves. More popular as a garden plant will be, no doubt, the double-flowered variety of the common European Bramble (*Rubus fruticosus*), with its large double or semi-double white flowers, tinged with pink, in which a large part of the stamens have developed into petals. In common with nearly all the innumerable varieties of the European Bramble, it is a very hardy and vigorous plant, growing and spreading rapidly. The variety upon which the leaflets are deeply cut and divided (*Rubus laciniatus*) is a handsome plant, useful for covering rocky banks and other waste places in the garden; it might be seen more often to advantage in this country.

Among the late flowering *Spiræas* now in bloom, the most showy is *S. Douglasii*. It is a native of the North-west Coast, from Puget Sound to northern California, and with two eastern American species (*S. salicifolia* and *S. tomentosa*) forms Koch's small section *Spiraria*, distinguished by its paniced flowers. *S. Douglasii* has simple erect stems, three feet or less high, covered with oval or oblong, coarsely serrated, simple leaves, densely coated on the under surface with white tomentum, and terminated with a dense, elongated panicle of very handsome, bright rose-colored flowers, which remain a long time in perfection. This is one of the showiest of the late blooming shrubs in the collection. *Spiræa salicifolia*, the Meadow Sweet of the Eastern States, is a variable and widely distributed plant, being found in eastern North America, where it bears white flowers sometimes shaded with pink, and from western Europe through Siberia to Mongolia, Manchuria and Japan. In the old world variety the flowers are pink or rose colored. A great deal of attention seems to have been paid to the cultivation and improvement of this plant in some parts of Europe, more especially in Russia, and many varieties (under innumerable names) have been sent to the Arboretum from the St. Petersburg and other Continental gardens. Some of these show traces of the blood of *S. Douglasii*, and many of them are distinct in the color of the flowers, and in their time of blooming, several weeks elapsing between the time the first and the last of the series expand their flowers. The strongest growing and perhaps the showiest of these varieties is that known in many European gardens as *S. Bethlehensis*, a vigorous plant, probably a hybrid, with large, showy panicles of flowers. *S. Billardi*, raised many years ago by the French horticulturist whose name it bears, is worth cultivating also for its showy flowers.

The last of the Spindle-trees (*Euonymus*) to flower here is the North American Burning-Bush or Wahoo (*E. atropurpureus*), a tall shrub or shrub-like tree, found from western New York to Wisconsin and in the Southern States. The flowers are small, very dark purple, and not showy. In the autumn, however, when it is covered with its abundant bright crimson fruit, drooping on long peduncles, this little tree is a beautiful object, although less showy, perhaps, than some of the varieties of the European Spindle-tree, in which long cultivation and careful selection have developed large and showy forms of fruit. The Wahoo (which must not be confounded with the Elm (*Ulmus alata*), which is popularly known in the Southern States as "The Wahoo") is a not infrequent inhabitant of old-fashioned American gardens.

Northern swamps are now white with the flowers of the Swamp Honeysuckle, *Rhododendron (Azalea) viscosum*, the last of the whole family to flower here, and well worth a place in the garden, on account of its late and deliciously fragrant clammy flowers. It is found from Maine to Kentucky, but generally near the coast, and sometimes grows to a height of eight or ten feet. It requires the same treatment and can be grown as easily as the other plants of its class.

July 11th.

7.

The Forest

The Forests of Europe as Seen by an American Lumberman.

WHILE in Europe in 1885 I noticed in Germany, particularly on the lower Elbe, the Spree and generally over the old worn out lands, that much was being done to preserve the old and replant new forest trees in regions from which 200 or 300 years since the forests had been destroyed. At the schools of forestry intelligent men asked, "Why do not you Americans learn by our errors and do something to save your forests now?" The only reply I could make was that I hoped we might begin to save before we were driven to it by necessity as other nations have been.

The new forests over Prussia from Hamburg by way of Berlin through to Breslau and in the circle with the distance from Berlin to Dresden as a radius are doing well. It is common to see plantations largely of pine of from forty to six hundred acres ten, fifteen, thirty-five and fifty years old, all within a few miles of each other, the different heights of trees on the land-lines sharply showing their different ages. Some of the older trees are sixty feet high and eighteen to twenty-five inches in diameter, all growing very even and thick. These plantations are kept clean, with the lower dead branches broken off for use by poor people as fuel, and all this on land that looked light and as if it had been run out like the "old fields" of the Carolinas and Virginia. Many of those new forests in Germany were being cut clear for the timber, lumber and wood, others were being preserved with the best trees cut out and sold under care of foresters. The land itself was being revived and was approaching a virgin condition again. These new forests now furnish the timber of the country.

In the forests of Saxony and Bohemia, up the Elbe and Spree, more particularly of Saxon Switzerland and up the river Elbe into Bohemia, I visited some twenty or thirty mills that were sawing timber grown upon the streams tributary to these waters. Some good trees were worked up here thirty and thirty-six inches at the butt end, and cut the whole length, say sixty to seventy feet long. In the larger mills the whole log is run through gang saws, and then the product is tied up as one log by itself and so sent to market slab and all. The saws used were thinner than ours. Very small logs, too, often no more than five inches in diameter, are cut. The price of this lumber was no more than it is in the Middle or New England States, but of course the Europeans use less lumber than we do. From an extensive examination of Germany, Austria, Belgium and north-eastern France, northern Switzerland and the Duchy of Baden, I should say that under the wonderful care and intelligence of the present system the forests were quite keeping up with the demand for the common lumber-wants of the country, and some even being shipped to Portugal, Spain and the Mediterranean. I visited the saw mills on the Necker and the Rhine, climbed the Feldberg and the Taunus, and saw foresters carefully cutting and sawing the windfall trees and planting a new one for every tree taken out. The Government is doing so much for the forests everywhere. In the little province of Baden, smaller than some of our New England or New York counties, over 100 men are employed and paid by the Government to care for the woodlands. In Saxony and Bohemia I went to the homes of the foresters and found some of them experts in various branches of natural history. The heads of departments were graduates of some school of forestry, and they were advanced as they deserved and held their offices for life or good behavior. The Germans have waited until their timber was cut off before they began to replace it, but they are now prosecuting the work with rare patience and skill.

In the summer of 1887 I visited again the British Isles, and examined the lumber industry of the eastern coast,

of Edinburgh particularly. I saw much of the lumber of Norway and eastern Russia as it was brought into England. There is little large or wide timber left in those countries. Much the same process of stripping forest areas has gone on there as in the countries before named. There is much less timber in Norway, Sweden and Russia available than is generally supposed and its quality is poorer—sound enough, but hard and full of knots, very much like the lumber of lower Europe. Evidently the virgin forests of the north temperate zone are in North America. The impression created by the European forest examination made by me in 1885 and 1887 is this: Trees will grow if properly planted and cared for, but it is like the first attempts in raising the tame grasses from the old farms of the east in the virgin prairies of the west. The soil seems rich enough to grow Timothy, but the cultivated grass will not flourish until the wild "nature" of the soil is subdued by many plowings and trappings of the tame cattle; even so, when land has been stripped of woods and worn by farm crops, it is hard to re-cover it with forest. Just here the aid of science is needed. Here is work for the schools of forestry that have done so much for France and Germany. The forest restoration of Europe is due to science, and is accomplished by men trained for the purpose.

Again the more regularly distributed rainfall of western Europe, especially in the north and Baltic countries, is more favorable to the restoration of forests than in America generally, though in some parts of Europe the soil is so much worn out it is almost impossible to make trees grow. Indeed, all over Europe, and especially east and south of the Mediterranean, and over most of the older settled portions of the Eastern Hemisphere, it seems to have been the especial mission of the Aryan race to destroy and remove the forests from the face of the earth.

In the lumber yards of England, Scotland, Hamburg, Bremen, Antwerp and France I saw much of the timber from America. Our forests are drawn upon to supply the waste of centuries in the old world. It is time we began to think of husbanding our own resources. *H. C. Putnam.*

Eau Claire, Wisconsin.

Correspondence

To the Editor of GARDEN AND FOREST:

Sir.—The writer was much interested in the editorial, "Hardy Fruit Trees," in your issue of June 27th, especially as the conclusions reached coincided closely with those reached in my thesis on "The Crossing and Hybridizing of Fruits," prepared for graduation last year at the Iowa Agricultural College. In American fruit-breeding recourse has been had as yet to native species only in the case of Grapes, Raspberries, Plums and Strawberries. The results have been very encouraging, but a vast field of work still lies fallow. Even with the fruits mentioned, much work remains to be done with the local forms found in the extreme north-western Prairie States. The *Prunus Americana* of the eastern and southern States differs greatly in hardiness from the same species as found in Dakota. This illustrates the fact that the coming orchard and small fruits of the extreme north-western section of the Mississippi valley must originate from the local form of the native species and from varieties imported from similar extreme climates, such as Russia, where many centuries of natural selection have weeded out the tender plants.

Our native species of Cherry, Apple, Gooseberry, etc., all lie untouched, awaiting the hand of the horticultural experimenter. Of the work done in preceding centuries we can take advantage by crossing and hybridizing, which, in fact, are only methods of abridging the process of evolution, by introducing potent causes of variation. In all cases cultivated species from as extreme climates as possible should be used to infuse the desired quality and size.

Besides those mentioned, a considerable number of other native species, such as the Papaw and Persimmon, may be improved by cultivation, selection, and, wherever possible, by hybridization.

This is a proper field of work for the new Agricultural Experiment Stations, and is attractive alike from a scientific as

well as a practical standpoint. It would contribute greatly to our knowledge of the limits of species.

The writer last year sent circulars of inquiry to a large number of experimenters in the United States and Canada, and thus collected a considerable amount of valuable information bearing upon this subject. The general opinion greatly favored crossing and hybridizing as a means of improving our fruit trees and plants.

The work with Russian and American Apples, Cherries and Plums has been begun by Professor J. L. Budd at the Iowa Agricultural College, and gives promise of valuable results.

Atlantic, Iowa.

N. E. Hansen.

To the Editor of GARDEN AND FOREST :

Sir.—I have been interested in the discussions relating to terraces and verandas and other additions to dwelling houses, and have been waiting for some one to suggest a better arrangement than any yet mentioned. This is a terrace with a tiled floor and a frame over it, upon which, during the summer, an awning can be let down in the day-time and rolled back in the evening, while the whole upper structure can be entirely taken away in winter. In summer a terrace of this sort will be cooler by day than one that is not shaded, and in the evening it will be cooler than a veranda, because there will be nothing overhead when the awning is rolled back. In the winter a veranda shades the windows, and the removal of the frame and awning from the terrace freely admits the sunshine, when every ray is needed.

With such an arrangement the terrace can be turned into a summer conservatory for many of the tender evergreens and other plants that would perish under the broiling sun, and for any fine green-house plants, like specimen Palms or plants in flower.

B.

Newport, R. I.

To the Editor of GARDEN AND FOREST :

Sir.—The Itasca Basin, mother of the Mississippi, proves as full blooded as her offspring has indicated. A timbered surface, with porous soil seldom frozen and deeply underlying clay beds, collects the drainage of many square miles and pours this sheet of spring water into the lake and its feeders. Every drop in this ideal reservoir is needed for navigation, manufactures and city water supply.

Clearing the land will cause deep freezing and quick melting of the snow, running the snow water off on the surface with a freshet.

Clearing has commenced, and this land will be stripped, unless we learn to feel, with the Swiss, that the trees which hold the avalanche bleed when they are cut.

H. B. A.

Recent Publications.

Homestead Highways. By Herbert Milton Sylvester. Boston: Ticknor & Co.

Mr. Sylvester, who dates his book from Quincy, Mass., but whose memory dwells amid the hills and woodlands of New Hampshire, found many pleased readers, a few years ago, for a little book called "Prose Pastorals." The same title might just as well have been used for his present volume, which, through its seven chapters dealing now with nature chiefly and again chiefly with rural mankind, preserves as the keynote a spirit of calm, open-eyed, sensitive and not unpoetic meditation. "An Old-Fashioned Festival" treats in a fresh and charming way of the oft-described scenes of Thanksgiving Day and "A Winter Resort" pictures the country school. But the chapters on out-door life are perhaps still more attractive, notably the two on "Running Water" and on "A Snug Corner" of the woods in winter.

In "*Society in Rome Under the Casars*," recently published, Mr. W. R. Inge, M.A., speaks of the parks and gardens of the Romans in the first century as follows: "Partly from want of appreciation of open park land, partly from paucity of shrubs and flowers, neither park nor garden was in keeping with the splendor within [the house]. The flowers were of simple kinds and lacked variety, but they were grown in large quantities, for the graceful custom of wearing garlands, and even the rites of religion, made a constant and plentiful supply necessary. Roses, Lilies and Violets were the only flowers cultivated on a large scale. Green-houses and hot-houses for flowers and fruits were first introduced in our period, and, of course, were soon very common. Winter Grapes and Melons were grown under glass, and we hear of forced* Roses

and Lilies. Fruit trees were planted, sometimes among other trees, sometimes in orchards. The Romans were well supplied with fruit. They had several kinds of Apples, no less than thirty sorts of Pears, Plums, Peaches, Pomegranates, Cherries, Figs, Quinces, Nuts, Chestnuts, Medlars, Mulberries, Almonds and Strawberries. Their ornamental trees were few in number, and this doubtless led to the artificial shaping, before alluded to, which was carried to absurd lengths at the close of the first century. The garden was always intersected by a path, which could be used for riding, walking, or taking the air in a litter. Porticoes for lounging in the open air, and elaborate baths, were comforts not likely to be forgotten in Italy."

Periodical Literature.

Dr. C. C. Parry, the distinguished botanical explorer, contributes to the June number of the *Overland Monthly* (also issued separately) an interesting account of Rancho Chico, General John Bidwell's California Ranch, on the lower Sacramento, near the site of the historical Sutter's Fort. It has long been known as one of the best and most productive farms of the Pacific Slope, abounding in features of natural beauty and famous for the hospitality of its enlightened proprietor. Dr. Parry describes pleasantly the history and the situation of Rancho Chico, the native plants which adorn it and the crops it is made to bring forth. The Ranch is situated in one of the best fruit producing regions in the state. "The Fig and the Olive, the native Walnut and its Asiatic relative, flourish in unrestrained luxuriance. There is no other section in which the Cherry bears more plentifully or with greater certainty of return." One tree in the orchard produced last year nearly a ton of fruit, which sold for an average of ten cents a pound, making nearly two hundred dollars as the return for a single tree in one season. "In May the Apricot begins to yield its golden fruit, and before its day is passed, Apples, Pears, Peaches, Plums, Almonds, Nectarines, Prunes, Quinces and the endless variety of Grapes come one after another to fill their places in an endless round. Aside from table Grapes, all the vineyard product of the ranch is made up into raisins. There is something in the quality of climate and soil that is peculiarly favorable to the culture of the Malaga, and the finished product is sweeter than the average and far excels the more famous Fresno brands in the thinness and tenderness of skin."

There are 25,000 acres in General Bidwell's farm, and some idea of its fertility and of the extent to which it is cultivated, will be gained from the following enumeration of the average crops which it produces: 100,000 bushels of wheat and 50,000 bushels of barley; 1,000 tons of hay; the meat product requires the slaughter of 300 cattle and 1,200 sheep; a dairy of 150 cows produces a gross income of \$1,000 a month. The cannery turns out 370,000 two-pound cans of fruit, not including great quantities of dried orchard fruits. During the height of the fruit season more than 500 persons find employment on the ranch. The most interesting of the numerous illustrations joined to this article is that of a noble specimen of the deciduous White Oak of California (*Quercus lobata*), known as the "Sir Joseph Hooker Oak," in honor of the English botanist who visited General Bidwell during his journey in this country in 1877. The photograph from which the illustration is made was taken in winter, and exhibits the graceful pendulous ramification of this tree much more satisfactorily than we remember to have seen it depicted before.

Recent Plant Portraits.

Botanical Magazine, June.—*CATASETUM BUNGEROTHI*, *f.* 6998; a very striking, free-blooming Venezuela Orchid, with flowers varying from white, the hollow of the spur ochreous, though pale yellow-green to golden.

KOEMPFERIA SECUNDA, *f.* 6999; a common plant in the Khasia Mountains, south of the Assam valley; it has loosely tufted, leafy stems, six to ten inches high, with terminal, few-flowered spikes of showy rose-colored flowers.

HUERNIA ASPERA, *f.* 7000; *Huernia* is an African genus, distinguished from *Stapelia*, which it closely resembles in habit, by its campanulate corolla. The plants of this genus are all south African, with the exception of the species here figured, which is from Zanzibar. Its interest is botanical rather than horticultural.

PALICOUREA NICOTIANÆFOLIA, *f.* 7001.

CASSIA COQUIMBENSIS, *f.* 7002; a glabrous shrub, very common in the neighborhood of Coquimbo, in Chili, with axillary

* "*Festinate*" Mart., 13, 127. See also on the subject Mart., 8, 145 4, 21, 5.

cymes of conspicuous yellow flowers an inch and a half in diameter. It belongs to that section of this enormous genus in which the seeds are parallel to the septum in the two-valved, flattened pod.

ARAUCARIA CUNNINGHAMI GLAUCA (cones of), *Gardener's Chronicle*, June 2d.—From the fine specimen of the glaucous-leaved variety of the "Morton Bay Pine," grown in the Temperate House at Kew. It is an important Australian timber tree, forming vast forests in the valley of the Brisbane River.

SABAL PALMETTO, *Gardener's Chronicle*, June 2d.—A view of a fine group of this well known Florida tree, growing at Jupiter Inlet, on the east coast, from a photograph by Mr. James M. Codman, in the Kew Museum, although credit is not given for it to that establishment.

PINUS CANARIENSIS; *Gardener's Chronicle*, June 7th.

YUCCA FILIFERA, *Gardener's Chronicle*, June 16th, f. 97 and 100; from photographs by Mr. James M. Codman in the Kew Museum (also without credit) and already published in *GARDEN AND FOREST* (April 11th, 1888).

Notes.

The Second Annual Meeting of the Illinois State Forestry Association will open at Springfield, in the State House, on the morning of the 8th of August.

Seven and a half tons of grapes to the acre is a good average yield for a California vineyard, although ten tons an acre is not an unusual crop, and, in a well authenticated instance, fifteen tons an acre have been produced.

Professor L. H. Baily, Jr., of Cornell University, sails for Europe the last of August to visit experiment stations and study the horticulture of the countries he visits. A leading object of his trip is to collect data for the completion of textbooks of horticulture, which he now has partly written.

The annual excursion of the Gardeners' and Florists' Club, of Boston, was a great success, and the gardeners, who have now well earned a little leisure after the labors of spring planting, thoroughly enjoyed their sail on Massachusetts Bay and their visit to the various islands and other points of interest.

At the weekly meeting of the Massachusetts Horticultural Society on July 21st, a new white Pansy was shown, which is quite a novelty, from the fact that it is semi-double, the stamens having been changed into petals. It is of good substance, free flowering and entirely white. It will prove an acquisition for the commercial florists.

Sweet Peas have been greatly improved during the past few years. New colors of remarkable clearness and brilliancy are being constantly introduced. These flowers are great favorites at Newport, Bar Harbor, and other eastern summer resorts, and in no part of the country are they grown so successfully as in the vicinity of Boston, where they are used by the florists in great quantities.

Dutch bulb-growers having found that the sale of cut blooms of Hyacinths and Tulips, which at one time were sent to the London markets in immense quantities from the bulb-fields of Holland, interfered with the sale of bulbs, they have formed an association, the members of which agree not to sell the flowers of these plants. A boycott is established against members of the association who infringe its rules. More than 2,000 bulb-growers have already joined this association.

The railroads have manifested an unwillingness to grant to delegates to the meeting of the Society of American Florists at New York City the reduction in fares usually given to such gatherings. But, nevertheless, all indications point to an immense gathering, and the coming convention will certainly be the largest meeting of florists and gardeners ever convened in this country. Programmes and all information may be obtained by addressing Secretary Wm. J. Stewart, 67 Bromfield Street, Boston.

The Fruit Growers' Association of Ontario held their summer meeting on July 11th and 12th at Picton, Prince Edward County. Rev. Geo. Bell, LL.D., of Queen's College, Kingston, read an instructive paper on Canadian Forests, and the subject of improving fruits by hybridizing and selection was treated by Mr. P. C. Dempsey, of Albany. The meeting was largely attended, and leading specialists in various departments of fruit and flower culture and in forestry participated in the discussions.

Hon. Sidney Root, President of the Atlanta, Georgia, Park Commission, sends us the photograph of a fine Willow-Oak tree now standing in the grounds of E. W. March, Esq., of that city. It was carried from south-western Georgia in 1858, when its trunk was not as large as a musket-barrel. It now measures seven feet six inches in circumference three feet from the ground, and its branches extend over a circle seventy feet in diameter—a remarkable development for a tree thirty-three years from the acorn.

The New York Forestry Commission has revoked all the custodianships under which the islands of Lake George have passed into the control of a few private individuals. Many of the men who were made custodians of the islands have built fine houses, and made extensive improvements upon them, under authority granted by the Land Commissioners. The action of the Forest Commission will cause some hardship to the persons who have had the use of the state's property, but it will be approved by public sentiment.

A recent bulletin of the Ohio Experiment Station gives the most effective methods used in the Prairie States to check the migrations of the chinch bug. But after all the trapping in furrows, burning over stubble, pouring a line of coal tar about fields liable to invasion and other precautions, the devastation by this insect can hardly be held within bounds while the weather is dry. Professor Forbes estimates that in southern Illinois the losses from the depredations of the chinch bug, during five years past, have reached \$25,000,000.

The fondness of the Germans for planting memorial trees is well known. Lindens are most often chosen for the purpose, this tree having gradually usurped that place in the affections of the Germanic people which was once held by the Oak and being now considered the national tree. On the occasion of a recent visit paid by General Moltke to the Spath nurseries near Berlin, he planted an American Linden, of the variety which is known in German nurseries as *Tilia Americana Moltkei*. Near the spot it occupies Prince Bismarck planted a few years ago a specimen of *Tilia argentea*—the beautiful Hungarian Linden to which reference was made in the article on the trees in Central Park recently published in this journal.

Some excitement has been caused among Orchid growers in London by the breaking up of several large collections. No fewer than five of these have been or will be dispersed within a few weeks. The first was that of the late Mr. John Day, a genuine Orchid lover, an assiduous collector of all classes of Orchids, popular or merely "botanical." It was a collection rich in species one seldom sees except in botanical collections. Then followed the small, but very choice and exceedingly well grown, collection of Dr. Duke, a devoted amateur and a true lover of his plants, and the fine collection of Mr. Southgate, at Streatham. Immediately after was sold the celebrated collection of Mr. Philbrick, an eminent lawyer, likewise a great lover of his plants, of which he had a wide and intimate knowledge, and the fifth, by far the most extensive and most important, is that formed by Mr. Lee, at Downside Leatherhead, in Surrey. This Downside collection is immense and wonderfully rich in all that is choice among Orchids, and for the most part admirably cultivated. The first portion has been disposed of at public auction and it will take eight days to sell the entire collection.

The death of the Rev. E. P. Roe, at his home at Cornwall-Hudson, on the 19th of July, deprives us of a collaborator who, we hoped, would do much during many years to come to interest and instruct our readers. Although Mr. Roe's reputation rested most largely upon his labors as a novelist, his horticultural works would have sufficed to win him solid popularity had they been his only productions. The best known of them is, perhaps, "Success With Small Fruits," originally published in the *Century* (then *Scribner's Magazine*), and afterwards issued in book form with the same beautiful illustrations; but others of almost equal merit are "The Culture of Small Fruits" and "Play and Profit in the Garden." It was not as a *dilettante* that Mr. Roe wrote on horticultural subjects. From the year 1874 until his death he was in business as a nurseryman and fruit-grower at Cornwall, and his books were the outcome of practical experience, and chronicled actual, long continued successes. His flourishing gardens and orchards were one of the sights of Cornwall, and the generous hospitality with which he met all who were interested in like pursuits with himself will long be remembered by hundreds of his visitors. Mr. Roe was but just fifty years of age when he died, quite suddenly, of an attack of angina pectoris.

Irrigation Problems in the Arid West.

IN a recent issue we considered the potentialities of the arid regions of the far west under irrigation. How best to develop these, how best to make fertile and populous this vast extent of country, is a question of national importance. It deserves the attention of both national and state or territorial governments. Much has already been done by individual and corporate effort in the making fertile of large tracts. Large as is the amount of land that has been thus brought under cultivation, it is but a sample of what may be done with comprehensive, systematic undertakings. There must eventually be carried out works of such magnitude that private means can hardly be looked for to take them in hand until their assured practicability has been demonstrated and the attention of great capitalistic enterprises is turned towards the field, as it has towards the construction of railways on a continental scale. The utilization of the waters of important streams that come under the jurisdictions of more than one state or territory involves considerations of equity, and often the harmonizing of conflicting interests, in a way to call for the participation of the national government, as well as does the fact that the greater portion of the land to be improved belongs to the national domain. The splendid work accomplished in India by the British government in the construction of thousands of miles of great irrigating-canals, with the result of making India a strong, and possibly dangerous, rival of the United States in the wheat-markets of the world, gives an idea of the field open to our government. Not until the precipitation from the mountains of the arid region is spread over every possible acre of the plains, can the subject be regarded as settled. It has been urged that the national government appropriate large sums for the construction of irrigating works on an extensive scale in connection with the principal streams; but this policy seems undesirable, for under our present system it would almost surely lead to wasteful expenditure, if not ill-devised schemes. The best means seems to be some method of encouragement to private capital. This might be done either by special acts adapted to particular cases, or by a general law applying

to all irrigation projects beyond a certain magnitude. This method has been certainly most beneficent in its application to railways, for without the encouragement thus given, chiefly in the shape of land-grants, the railways would not have been built and the country would have remained undeveloped and unsettled; the national lands consequently worthless. The railways now need no such encouragement and they build readily through that portion of the country without it; therefore it would be gratuitous to give them a bounty for doing what they are eager to do, and the land-grant policy has very properly been abandoned. It would probably, however, be a good policy for the government to encourage, for the present, the construction of extensive irrigating works, by granting to the parties undertaking them alternate sections of the land thus improved. Otherwise it might be many years before such needed works were undertaken. Government land now absolutely worthless would thus be made very valuable, with rich and prosperous populations created in the wilderness. To guard against possible abuse, it might be provided that the improved land thus obtained by the companies should be sold to settlers at certain fixed and reasonable prices. In this way, for instance, the enormous flow of the Colorado River—the diversion of which for irrigation involves peculiarly difficult and costly engineering—might be utilized, and millions of acres in the Mohave and Yuma deserts and on the Sonora mesa, in California and Arizona, made fertile.

The state and territorial governments have a concern in the matter no less than that of the federal government, their function being administrative, as well as incentive like the latter. It is of such immense importance that the irrigating works should be constructed and operated to the best possible advantage of the public, that, in the states and territories of the arid regions, boards of irrigation-commissioners are more essential than even the railway commissions that have almost universally become the rule. The whole subject of irrigation should be entrusted to these commissions, whose office should be advisory as well as regulative. Colorado ranks probably foremost in having adopted an enlightened system of this kind, and is reaping the benefits in the shape of a remarkable growth of her agricultural interests, which are placing the state on a more secure foundation of prosperity than mining, which has been her chief industry, could ever do. The state is divided into twenty-six water-districts, with a water-commissioner at the head of each, in charge of all matters concerning irrigation. The state engineer has supervision of matters relating to his department. The laws of the state provide methods for regulating outflow and distribution, for organizing enterprises either on a joint stock or co-operative basis, the supervision of water-rates, and the adjudication of disputes.

California also has a well-devised irrigation code. The irrigation laws of Arizona are modeled on those prevailing in California before revision, with some modifications, and need improvement. The irrigation laws of New Mexico are substantially the same as when the territory was a Mexican province. For the development of its great resources a thorough remodeling is needed.

In each state and territory there should be, under the supervision of the irrigation commissioners, a thorough topographical survey of the water-supply, actual and potential, indicating the best lines for canals, the amount of flow in the various streams and the amount that would go to waste without storage, the spots in the valleys and among the mountains where the water of either permanent streams or of torrents may be husbanded by impounding, and where water may be obtained either by artesian or ordinary wells. The knowledge thus given would be of enormous value in promoting the development of irrigation, for settlers could proceed with confidence to utilize the resources pointed out, saving them much uncertainty and possible loss. Therefore such a survey, however costly, would pay for itself manifold.

The study of irrigation methods should be a leading and particular feature of those agricultural experiment-stations established by the aid of the national government in the arid states and territories. For the most part the prevailing systems are characterized by great extravagance in the use of water, so that with proper economy the present supplies could be made to irrigate a much greater area; in some instances probably even twice as much. The best means for the prevention of waste can be studied and pointed out at these stations, and, when ascertained, their adoption should, in the interest of the public, be made compulsory. The products most suitable to irrigation can also be determined at these stations. Irrigation is particularly adapted to horticultural operations. Fruit trees, for instance, require a very much less quantity of water than either grain or grass crops, and while yielding a greater return of profit to the acre, a much greater area may be cultivated from a given supply of water. It is probable that some method of sub-irrigation can be effectively adapted to fruit-culture, since the economy of water would repay the increased cost, while the large returns from fruit-culture in those regions would warrant the considerable expense of preparing the land. Sub-irrigation would almost entirely prevent the loss by evaporation, which is enormous in those regions, and, moreover, it would probably offer a remedy for the malarious conditions so apt to accompany irrigation, for the water would be absorbed beneath the surface, instead of generating malarial germs or gases through the decay of vegetable matter in surface-evaporation under a hot sun. The best means for preventing evaporation in the storage-basins and in the flow of distributing canals, should also be studied thoroughly at these experiment-stations.

With the entire subject considered, and the results carried into practice in the way we have indicated, we shall see an agricultural development in the arid portions of our country that will give them rank in fertility, wealth and high civilization with the famous old cultures once developed under similar conditions in the valleys of the Euphrates and the Nile.

Occasionally some uninstructed person speaks of inexhaustible forests, but by this time it should be pretty generally understood that a forest can be made to yield indefinitely only by restricting its average annual production to its annual increase. The forest products of Maine, for example, diminished alarmingly after the White Pine and Spruce in that State had been recklessly destroyed for many years, and the entire extinction of its most important industry was threatened. But the people of Maine have learned a dearly bought lesson, and realize now that forests can be destroyed, even though they may have appeared inexhaustible, during the lives of one or two generations of men. The Maine forests are not managed in accordance with the rules of scientific forestry as these are understood in European countries, and beyond question the practice could be improved upon. Nevertheless, this practice is based upon the laws of nature and the necessities which arise from existing conditions, and it is upon these that any system of forest management, however elaborately its details may be worked out, must rest primarily. The Maine lumberman has learned that excessive and unrestrained cutting, supplemented by fire, will destroy any forest, and that a forest from which only the ripe trees are cut at stated periods, while the remainder are carefully protected and allowed in their turn to reach maturity, will continue to produce indefinitely, and to pay handsomer returns in the long run than it would under the usual American custom of indiscriminate cutting without regard to future production. The changes which have been gradually taking place for a number of years in the management of the Maine forests have already borne fruit in their improved condition and increased output. They restore to the Pine Tree State its position as one of the most important of the

lumber producing states, not in the actual product of the mills to-day, but in the promise offered by more intelligent forest management of a steady and constant supply of logs in the future. If the present ruinous practice continues to prevail in Michigan, in Wisconsin and Minnesota, it will not be many years before the annual timber crop of those three great states will fall below that of Maine, and perhaps of some of the other New England States. It is not easy to overstate the importance of the system of forest management which is now being worked out in the Maine woods, and which is all the more likely to succeed because it is based upon experience. Its eventual success means prosperity for the State; its failure practical ruin for a large part of it. Other States can learn much from Maine; and especially that by the patient application of a few sensible rules—rules which nature herself teaches—and by the use of a little forethought and a little common sense, a forest can be made more surely and permanently productive than property of any other description.

As we said some weeks ago, there is a growing love among the people of our cities for cut flowers of every description and every grade of costliness. For every variety of flower sold in the shops ten years ago, a dozen varieties may now be counted, and for every street vender who could then be seen, a whole troop may be seen to-day. At first it seemed as though the street vender merely sold at a lower price the stale or refuse stock of the florist—little button-hole bouquets or half-withered bunches of Roses. But he has enlarged his field of enterprise with the growth of patronage, and numberless hands must now be at work for him in suburban gardens and meadows. The Lilacs shown on the street this year were remarkable for quality as well as for quantity, and an especially welcome fact has been the advent of wild flowers in unprecedented quantities. The first to appear were "Pussy Willows," and then Marsh-Marigolds, which abounded at every step and were sold in large bunches for five cents. Since then we have had Buttercups, Field Daisies and Laurel in quantities, and, a greater novelty, the False Spikenard (*Smilacina racemosa*). Pitcher Plants and Magnolias have been offered, and every wild flower which may easily be procured will follow in due season until big bunches of Black Alder berries take the place of flowers. In addition to wild flowers, common garden flowers—Pinks, Pæonies, Roses, Sweet Peas, Corn Flowers and a host besides—began to appear in profusion as soon as the Lilacs were past, so that the New Yorker, even of slenderest purse, has been able to enjoy, almost as well as his country brother, nature's pleasant tokens of the passage of the months.

The Exhibition of Wild Flowers.

I HAVE frequently exhibited a small collection of wild flowers at fairs. They always excited an unexpected interest, however rude the collection may have been. At first I used herbarium specimens, placed in bundles according to their orders or genera, with cards attached containing the botanical as well as common names. But in this way they required constant watching to prevent displacement and destruction by careless visitors.

Recently, however, I have resorted to the woods and other places for wild flowers, and have exhibited them, generally with much satisfaction, in their fresh state.

My conclusion is that the following method is not only neat, showy and simple, but calculated to stimulate a desire in many persons to study the names and botanical arrangement of our native flora:

Take an ordinary table two or three feet wide, and as long as you please—say six to twenty feet. Tack a green or red colored muslin strip around the table to form a curtain, reaching to the floor. Cover the top with white paper. Then at a crockery store you can usually borrow

as many goblets as you need. Fill these nearly full of clean sand and enough water to fill the interstices nearly to the upper surface of the sand. Then put in your best selected plants, as shown in the illustration. The labels are written on cards about $1\frac{1}{2} \times 2\frac{1}{2}$ inches, inserted in a split at the top of the holder, which is about eleven inches long and less than one-quarter of an inch square. These holders can be made of any wood that will split straight. Our redwood answers well.

Thus we have one species in each goblet with a number of specimens convenient for examination. (See illustration.) Do not crowd the plants, and keep the goblets clear of each other. Many a fine display is spoiled by trying to show too many things in a small space. Some taste is necessary in arranging the goblets on the table as to height, color, etc.

Here in California we at all seasons have enough wild plants in flower for a nice show.

In the wet sand in these goblets the flowers will keep several days—some for two weeks—such as the *Calochortus*, *Oenothera*, *Godetia*, *Chlorogalum*, *Trifolium*, *Aquilegia*, etc. Some of the grasses are beautiful, and placed in goblets as above, will throw out their flowers in little tassels, which remain for several days unchanged.

These wild flowers in a flower-show contrast beautifully with the cultivated ones, and furnish an excellent illustration of the difference between the wild and the cultivated.

C. L. Anderson.

Santa Cruz, Cal., July, 1888.

[Collections of wild flowers have been an interesting feature for a number of years at the exhibitions of the Massachusetts Horticultural Society. The flowers are generally crowded together in bunches and placed in narrow vases of water. They soon wilt when treated in this way; and the collections lose much of the beauty and attractiveness they would possess if more taste could be displayed in their arrangement and in grouping the different varieties. Dr. Anderson's suggestion is one which might be tried with advantage at Eastern flower shows.—Ed.]

Wild Flowers for Exhibition.

The Flora of the Florida Keys.

A BOTANICAL survey of that unique portion of our country known as the Florida Keys confirms an opinion that would naturally be formed after studying a map—namely, that the flora of these islands is nearly, if not quite, identical with that of the coast region of the neighboring Antilles. Among the very few species which botanists do not know to grow elsewhere—though it is probable that they may be found in more southern regions—is the newly discovered *Pseudophanix Sargentii*. This interesting Palm is confined to two of the keys, namely, Elliott's and Long, which are over fifty miles distant from each other. On account of the small number of these trees and the precarious conditions under which they grow, they might have disappeared wholly from the world but for their timely discovery by Professor Sargent and the enterprise of Messrs. Reasoner Brothers, of Manatee, in obtaining plants and seeds for cultivation.

The renewed interest which this discovery has awakened in a region which has long been famous among naturalists and lovers of nautical adventure, seems to warrant a brief account of some botanical observations on these islands made by me

during several cruises since the year 1886. A botanical survey of the Reef Keys reveals several marked characteristics, of which the three following are most important:

1st. The number of species is small as compared with similar areas elsewhere, the total number being about 230, which is scarcely one-fourth of the number that is usually to be found in a region of similar extent.

2d. The proportion of woody plants (trees and shrubs) is large, being one-third of the whole number, while in the State of Florida as a whole the proportion of woody to herbaceous species is as one to seven.

3d. The species, as a rule, belong to tropical or sub-tropical orders, or to orders which are most largely represented in more southern latitudes. Thus we find five species of the Myrtle family, which is not represented in other States, and there are fourteen shrubs and trees of the *Cinchona* family, while but one is found in other States. On the other hand, there are no representatives whatever of those large and important orders, *Ranunculaceæ*, *Caryophyllaceæ*, *Saxifragaceæ*, *Onagraceæ*, *Umbelliferae*, *Polemoniaceæ* and *Liliaceæ*, and but one each of the *Cruciferae*, *Rosaceæ* and *Amentaceæ*, each of which orders has from 140 to 270 representatives in the United States.

These peculiarities are easily accounted for. In the first place, these keys present no material differences of altitude and latitude, and very little as regards soil, and differences in those three respects are the leading factors in determining the richness or poverty of the flora of any section. On these islands there are no hills or mountains, no brooks or rivers, no valleys or fresh water swamps, no clay, loam or siliceous sand. The soil consists throughout of coralline and sedimentary lime-rock, calcareous sand and a little mould resulting from the decay of vegetation. The rocky soil is permeated by veins of brackish water, and neither salt nor lime is favorable to great diversity of vegetation.

There is lack of silica for grasses and sedges, and the conditions do not favor that luxuriant growth of Ferns and Orchids which might be expected in this latitude. On the mainland, around the Everglades, there are forests more tropical in appearance than any on the keys. As regards natural vegetation, the keys improve all the way from Key West to the upper end of Key Largo, and there is a corresponding improvement in their adaptation to farming or gardening purposes.

As the best lands for cultivation are those that support the best forests, the latter have been destroyed, in great measure, by the clearing of land, the favorite Pineapple crop being one that is continually calling for new land. Fine old forests of Mastic, Mahogany, Crab-wood and scores of other interesting trees have been cut and burned to make room for plantations, and of some of the rare trees it is doubtful if any specimens are now to be found on the keys.

The botanical characteristics of all the Florida Keys, with the exception of one group, are essentially the same, the variety of species and difference in development being governed by varying elevation and fertility. The inner shores of the keys, and portions of their outer shores, are covered with almost impenetrable thickets of Red Mangrove (*Rhizophora*), among which are interspersed the Black Mangrove (*Avicennia*) and the Red and White Buttonwoods (*Conocarpus* and *Laguncularia*). Inside of these and on more exposed shores are species of *Coccoloba*, *Mimusops*, *Bumelia*, *Eugenia*, *Pithecolobium*, *Genipa*, *Casalpinia*, *Jacquinia*, *Erithalis*, and a few herbaceous plants.

On shores composed of the sand which results from the wear of corals and shells are found banks of the ashy-hued Sea Lavender (*Tournefortia gnaphalodes*), the greener Bay Cedar (*Suriana maritima*), *Borrchia*, *Cakile*, *Euphorbia glabella* and *trichotoma*, and certain coarse grasses. Inside of the littoral thickets, where there is more or less protection from sea winds, we come to rugged fields, cultivated or neglected. If cultivated, they afford a sufficiency of weeds and grasses to satisfy the botanist, but when allowed to lie waste for a year they become impassable by reason of the astonishingly rank vegetation which takes possession of them, everything being entangled and bound together by vines.

The chief natural impediment to locomotion in this almost tropical region consists in the abundance of tough and woody vines, and of trees which grow mainly in a lateral direction, sending out long, slender and often thorny branches near the ground. Several species vary in habit of growth, being shrubs in open ground and high-climbing vines when growing among trees. Such examples go to prove that the climbing habit is attributable to an attempt to reach direct sunshine, without which few plants can perform the important function of seed-bearing or reproduction.

There is no cause to fear the extermination of any herbaceous or shrubby plant, or of many trees, for the planters are constrained to leave skirts of forest around their clearings to protect their crops against the much dreaded hurricanes which sometimes visit these shores. For this reason none of the keys appear to be denuded of their forest covering, though we often perceive that the forests have receded a considerable distance from the outer shores. On the inner shores, and in many other places where the ground is too low for cultivation, the trees are secure against destruction.

There is a group of keys, to which allusion has been made, which presents a singular contrast to the range as a whole, in physical as well as botanical features. Throughout their whole extent of nearly one hundred and fifty miles in length the keys lie nearly parallel with the coast, but on the western side of the open waters called Bahia Honda, in a direction south-west from Cape Sable, there are several long keys whose trend is almost at a right angle with that of the other keys—namely, from north-west to south-east. The vegetation of these is strikingly different from that of the other keys, and most resembles the vegetation found on the mainland south-east of the Everglades.

This group of keys is covered with low and thin forests composed of *Pinus Cubensis*, *Thrinax argentia* and *T. parviflora*. The Pine is wholly lacking on the main range of keys. This and the Palmetto, which is represented by a few trees on Key Largo, are the only trees common to the southern and northern extremities of Florida. The Scrub Palmetto (*Sabal serrolata*) also occurs on these piney keys, and slender specimens of the Wax Myrtle (*Myrica cerifera*), which on the peninsula attains tree-like proportions. These four species, with two or three herbaceous plants, are the only ones common to the keys and the northern portion of the state.

A person who is acquainted only with the vegetation of more northern states, or with that of northern Florida, in traversing these keys will find scarcely a tree or herb identical with or even resembling those with which he has been acquainted. He may hear familiar names in use by the inhabitants, such as Cherry, Mulberry and Cedar, but on examination he will find the species thus designated to be entirely different from those which he has known by such names before. The curiosity is piqued at every step by some unfamiliar and interesting form of vegetation, and if the tourist be accompanied by one of the inhabitants he will learn much of the popular lore regarding names and uses, for these people are remarkably intelligent in regard to the vegetable and animal life of the region they inhabit. It will be found that almost all the adult inhabitants come from the Bahamas, that nearly all the trees and other plants are common to those islands, and, in short, that these islands have much more in common with the Lesser Antilles than with the Florida mainland.

A tour of the Florida keys reveals nature and society under such peculiar conditions that any one who has never visited this insular region may rest assured that there remains in store for him at least one source of novel and enjoyable experience, though he may have traversed the mainland of the United States from Maine to California. As regards conformation and soil, the inhabitants and their pursuits, the surrounding waters and the marine life they support, these coral islands differ essentially from all other portions of our vast country; but in no particular do they present so striking a dissimilarity as in the vegetation which covers them.

Foreign Correspondence.

London Letter.

THE Rose Show season began in London with a great exhibition at the Alexandra Palace in the last week of June, and rather early for exhibition blooms. On nearly every stand were fine flowers of Lady Mary Fitzwilliam, not a new Rose, and yet not common in cultivation, one of Mr. Bennett's great successes. Everybody is charmed with the Rose, its large size, superb form, and delicate, soft pink color. Then, again, its vigorous growth and free habit of flowering make it a first-rate garden Rose. It will certainly in time divide honors with the beautiful old La France, with which an uneducated eye always compares it. A sport from Lady Mary is called Lady Alice, which, I believe, originated in the Cheshunt nurseries. It differs from its sister Rose in color only, or rather in the absence of color, as the bloom is almost a pure white.

The best white hybrid perpetual at the show was Violette Bowyer, but this, as well as other white Roses, like Merveille de Lyon, will be better later in the season. A very rich-colored Rose is Ulrich Brunner, which still may be called a new Rose, and one that is likely to become a favorite, as the "build" of the flower is admirable.

Among the newer Tea Roses were Madame Cuisin and Madame de Watteville, both of which differ from most other Teas in color. Their flowers, instead of being entirely of one tint, have the petals exquisitely washed or flushed with a clear pink, while the form in both is perfect, especially in the half-expanded stage. Ladies fix upon these two Roses at once, and that is not a bad test of their merits. Grace Darling, another of Bennett's seedlings, was very fine, the richness of the color, a clear pink, being most pleasing. This is a Rose of the highest merit, not only for exhibition, but as a garden Rose. I saw to-day a bed of it, and every bush (there were a score or more) was literally covered with bloom—good, well-formed flowers, fit for exhibition. The habit of growth and foliage also being so vigorous, leaves nothing to be desired. It has been in flower in the open since the first week in June. A new Tea, shown by Mr. Prince, of Oxford, named S. A. Prince, has flowers of fine form, pure white, and scented strongly. It is, of course, premature to speak of its merits from exhibition blooms alone.

The new hybrid (also one of Bennett's) named Mrs. John Laing, was marvelously fine, as may be gathered from the fact that it took the first prize in the class for any kind of Rose. This Rose is a triumph of English Rose raising, and will tend to refute the prevalent idea that good new Roses can only be expected from the Continent. I have this week had a private view of a very beautiful new Rose, which Mr. Bennett has named Cleopatra. It is a true Tea, and if I were asked to compare it with an old sort I should say it was most like Catherine Mermet. But it is different, because finer in size, in form, in color and in perfume. It is one of the deepest "built" Teas I have seen, and the petals are large, of wonderful substance, as if chiseled out of some hard material. The color is a soft rose pink, with a suspicion of buff in the tint, and therein lies its peculiarity. The flowers, three parts open, are matchless in form, and the perfume is exquisite. Cleopatra has been seen by a few people only, but all agree that she is a veritable queen among Roses. I also saw at the same nursery the lovely Princess Beatrice, which has always seemed to me one of the very best of Tea Roses, and yet I was told the other day by an American nurseryman that it was considered of no value with you. But surely the flowers cannot have been seen in perfection. It could scarcely have had a fair trial, seeing that it was only sent out last June. The flower is large, the form perfect, the scent unsurpassable, and the color delights everybody. In fine blooms the outer petals are yellowish white, washed with rose, the inner all closely packed, an apricot yellow deeper towards the centre. The leaves have ruddy-tinted stalks, and are broad and of a very deep green color. If I were confined to a select dozen Tea Roses, Princess Beatrice would certainly be one of them. Another new Tea that has been talked about a good deal this season is Sappho, which Messrs. Paul, of Waltham Cross, have exhibited. I should compare it with Madame Berard, the near relative of Gloire de Dijon, as the blooms are alike in color, though different in form. Sappho has prettily-shaped flowers, very full and deep, and of a warm apricot yellow, and perfumed with the delicious scent characteristic of the old Gloire de Dijon. As a pot bush it is uncommonly vigorous, and the large number of flowers and buds show it to be a free flowerer.

This year has brought an exceptionally large crop of new varieties of the Polyantha Roses. Bennett has sent out two named Golden Fairy and Little Dot, which look uncommonly like twins. Both have tiny, very double flowers of a deep apricot tint, flushed with pink, but Golden Fairy is the lighter of the two, and the half-open

flowers look like the buds of W. A. Richardson, as the color fades at the edges of the petals, and gives that soft gradation of tint which all admire in the Richardson Rose. These fairy Roses are favorites with the florists already, as they work up so nicely as button-hole bouquets. The Cheshunt Pauls have shown a pretty new miniature Rose, called Red Pet, which is really a pigmy China Rose. The color is bright crimson, and though the blooms are not up to the florist's ideal, they are very telling on account of their color and profusion.

London, June 30th. W. Goldring.

New or Little Known Plants.

Cypripedium Californicum.*

THIS species of Lady's-Slipper, from the Pacific coast, is notable for its large leafy bracts and for the number of its flowers. The stem is sometimes two feet high, with numerous leaves, which continue to the top, with little reduction in size, the upper bearing in their axils a single, nearly sessile flower. The sepals and petals are greenish yellow, short, and nearly equal in length, the two lower sepals united into one, and about half an inch long. The saccate lip is but little longer, and is white or tinged and spotted with pink. The species is common in the mountains of northern California, growing in the open woods in damp soil or swamps.

S. W.

Plant Notes.

Two Rare Orchids.

ORCHID lovers have been interested of late in the simultaneous blooming of two rare plants in the possession of Messrs. Siebrecht & Wadley, at New Rochelle. The one, *Zygopetalum Sedeni*, formerly belonged to the Morgan collection; the other, a white variety of *Cattleya Gigas*, is certainly unique, since it is the only specimen known to exist. It came with a lot from Siebrecht & Wadley's collector in Colombia, who reported that there was a new species among them, but the mark for identification was lost in transit, and the plant was not known until it flowered last season. This year it is much increased in strength and size, and now bears four spikes of bloom.

The flowers are held boldly erect; the petals and sepals stand out, and are pearly white. The lip is large, crinkled into a little frill around the edge; it has a slight mauve tinge, like a delicate reflection. The throat is pale yellow, while on each side is the yellow eye-like spot which characterizes *C. Gigas*. There are four or five

**C. CALIFORNICUM*, Gray, Proc. Am. Acad., vii. 389; Bot. Calif., ii. 138. Pubescent, leafy; leaves ovate-lanceolate, acute, the upper narrower and acuminate; flowers three to six, on short pedicels in the upper axils; sepals greenish white, broad, acute, one-half inch long, the lower united to the apex, about equaling the narrower petals; lips slightly longer, oblong-ovate, white or pinkish, pubescent within at base; capsule reflexed.

Fig. 45.—*Cypripedium Californicum*.

flowers on each peduncle, large and showy. *C. Gigas* is generally regarded as the finest *Cattleya* known, and this new variety certainly deserves high rank among those with pale-colored flowers. It is probably the most striking novelty in Orchids now in the country.

The rare *Zygopetalum Sedeni* is an interesting garden hybrid, the result of a cross between *Z. Maxillare* and *Z. Mackayi*. It has narrow lanceolate leaves, and strong spikes of singularly

dark flowers. The sepals and petals are dark purplish brown, having a regular border of pale green; there are no bars, as in the case of the parents. The broad, round lip is of a brilliant purple, veined at the margin; the ruff a bright bluish purple. It is very distinct from any other *Zygopetalum*, though approaching *Z. Mackayi* in habit.

This plant was originally imported by Mrs. Morgan, but it never flowered until in the hands of its present owners.

Cultural Department.

Strawberries.

WE have tried most of the leading kinds of Strawberries here and have now twenty-eight varieties in our trial bed, but never have had a better Strawberry for our ground than Sharpless. It is a vigorous grower and retains its foliage in good condition throughout the summer; it is a heavy cropper, and its berries are exceptionally large, handsome and well colored, and with us it always ripens to the tips. But, except under high cultivation and in deep, rich, moderately moist land, it is not as desirable as some others. Our first berries this year were pronounced by connoisseurs as "most delicious," but this quality in Sharpless is unusual. In May abundant rain fell with no very high temperature—just such weather as is most suitable for Strawberries; June opened dry and warm, the best weather for ripening fruit, and to these causes are attributed the fine quality of the early berries. But the 16th of June brought hail and rain, and soon after the Sharpless berries assumed their characteristic sourness. Henderson, Hovey, Belmont and Wilder are of much better quality, but each one of them with us has some fault—lack of vigor, uneven ripening, small fruit, or other drawback—and even Louise and Mineola, both delicious berries and raised not far from here, do not, after a two years' trial, warrant us in using them for a main crop. As a heavy cropper and for use as preserves, the Crescent has been our favorite; but in its fresh state it is much more acid than Sharpless, and not nearly so large or handsome. For fine quality and aroma, our American varieties are not as good as the European Strawberries, but, unfortunately, these are of no use here. All the finest English varieties have been imported and grown on this place, and every one of them has been a failure.

Farmers and market gardeners, as a rule, grow their Strawberries in the open field, in rows two and one-half to three feet apart, and after the first year allow the runners to grow and remain, so as to form matted beds. But we have no room for horse cultivation. Farmers generally plant their Strawberries in spring; we always plant in August. And from this planting we not only get an excellent crop of fruit the next June, but we always get our very finest and largest berries from these young plants. And we so manage it as to renew half of our plantations every year; the young or one-year-old plants yield the finest berries, the two-year-old plants the heaviest crop.

Strawberries for home use should have the very best ground in the garden. Plan in spring where the next Strawberry bed is to be made, and then plant the ground with Peas, Snap Beans, Cauliflower, Beets, Onion-sets, or any other early crop that has time to mature and be off the ground before the end of July. It is not advisable that Strawberries should succeed Strawberries, still we have a piece of deep, moist land, so well adapted for Strawberries, that we have cropped it with them continuously for several years, but, notwithstanding the most liberal treatment and annual renewing, the plants are showing signs of enervation, and are not now as luxuriant as they used to be two or three years ago. After clearing off the summer crop apply a coating, two to three inches deep, of well-rotted farm manure, then double dig the ground with forks, being careful to break it up very fine and loose and keep the manure not deeper than four or five inches under the surface of the ground. Now measure and mark off the patch in rows twenty inches apart by drawing drills an inch or two deep. You may plant at once or delay till your plants are ready or convenience will permit.

Set out the plants eighteen inches apart in the rows, or, if an extra heavy crop is desired the first year, instead of setting them out singly set them out two together. Water well after planting, and in the event of dry weather, continue to water the plants two or three times a week while the drought lasts. The stronger the plants become before winter sets in, the larger the crop of berries they will bear next summer. Throughout the fall keep the young plants free from runners

and the ground perfectly clean and well hoed. About the middle of November break up some barn-yard manure fine and scatter it broadcast over the Strawberry ground, say an inch or more deep. Then again, about the middle of December, or after a firm frost sets in, and before lasting snow may be looked for, scatter some sea thatch, sedge or salt hay two inches deep over the plants, and so as to cover the whole patch. This mulching and covering prevents the plants from being thrown out of the ground by frost, and also saves the crowns and leaves from being injured by hard frost, searing frosty winds, or warm sunshine.

In field cultivation this straw covering is allowed to remain permanently, and the Strawberry leaves and flowers come up through it in spring, and it also serves as a summer mulching to keep the fruit clean. This is not our plan. The covering is removed early in April, the ground is cleaned and cultivated two or three times, and then about the 1st of May mulched again with straw material. In cultivating the ground use a prong-hoe; this loosens and breaks up fine the ground between the plants and allows a ready ingress for rain and air. Its effect upon the plants is shown in their vigorous condition. Of course, any time before the fruit begins to ripen is soon enough to apply the summer mulching, but by doing so early in May there is not the danger of injuring foliage or flowers, which there would be were it delayed till the end of the month.

Strawberries usually begin to ripen here about the 10th of June and last till the end of the month; this year we did not pick our first dish till the 14th of June, but they lasted till the 4th of July. Some days before they begin to ripen the cat-birds and robins are particularly voracious and peck every softening fruit. In private gardens, where these birds find shelter among fruit and shade trees, shrubs, bushes and vines, they are more numerous and destructive than in the open fields. We circumvent their attacks by erecting a temporary frame around and over the beds, and spread over it some netting, as described on page 176. As soon as the strawberries are gone the frame is removed. The netting is folded up and laid indoors till the first of September, when it is brought out to cover the grape-vines; the stakes are needed at once for Dahlias, Hollyhocks and Sun-flowers.

After the busy season is over the one-year-old plantations are thoroughly cleaned; weeds and straw mulch are removed, and the surface is loosened with a prong-hoe, care being taken not to injure the runners. This allows them to root readily. The two-year-old plantations are dug out and removed at once.

Before the end of July many of the runners are large and sufficiently rooted for setting out, and, the ground being ready, had better be transplanted at once. By using potted runners we can plant at any time, in dry or moist weather, and if the ground is not yet ready for the new plantation, we can lift and store the pot plants close together somewhere by themselves, and, in this way, are enabled to strip and clean the plantation from which they were taken. We use three and one-half and four inch pots; a double row of these is plunged in every second alley to the depth of half an inch below their brims; half fill them with sandy soil, then place a runner crown in each pot, bending the thread of the runner in, too, and then fill up with the same sort of soil. It is very easily and quickly done. The runners root readily in the fresh soil and in fourteen to twenty days have filled the pots with roots, and may then be severed from the parent plants, and the pots lifted out and removed from the beds. From this time till fruiting time next summer not a runner or a weed should be allowed to grow in the plantation.

Glen Cove, N. Y.

Wm. Falconer.

The Currant and its Cultivation.

THE currant crop has been a good one and the demand has been equal to the supply. It is not strange that so excellent a dessert fruit when fully ripe and so fine a canned fruit either alone or with raspberries for winter use should be in heavy demand. And yet in too many instances the quality and size of the fruit is allowed to suffer from the attacks of the Currant worm when a little hellebore and its timely application will prevent the loss. It is no uncommon spectacle even in gardens ordinarily well kept to see Currant bushes entirely stripped of their foliage, and the fruit ripening prematurely exposed to the full rays of the sun, inferior in size, and deficient in flavor. Such fruit is not fit for table use in a fresh state, neither can it be as good for canning. A tablespoonful of white hellebore to a two-gallon pail of water sprinkled on the bushes, will rid them of the pest and the fruit will ripen in perfection.

Of course there is no danger from the use of this drug even to those who hold that the flavor of fruit is impaired by washing. It is surprising, by the way, that water in the form of rain and dew does not rob a currant of its flavor, while dipping the cluster into cool clean water is said to have such a deleterious effect upon its quality.

Satisfactory crops of currants are only possible with good culture and a soil enriched with plenty of manure. The old Red and White Dutch varieties will produce fruit that will compare favorably in size with more modern introductions. The large fruit of the Cherry and Versailles Currants will depreciate in size by neglect and the productive qualities will be seriously impaired. As a rule I have found the latter to be the more productive of the two, while the White Grape is the best of all in quality. For the last decade these three varieties have been the most popular ones before the public. Some four years ago when Fay's Prolific was announced the claims for it were regarded as extravagant, but now after it has been duly tried it has been found to be one of the few new fruits which justified the rosy promises of the advertiser. Those who had the courage to try the new fruit in a small way regret now that they did not venture to buy more. Such a fruit is a fitting monument to any man's memory. A White Currant of as fine flavor as the White Grape with the other merits of Fay's would be a welcome addition to the list.

In Black Currants we have not found any great improvements. The most recent addition we have tried is Lec's Prolific, but the improvement over the old Black Naples is very slight, if any. While young there is a semblance of increased size and productiveness, but it does not seem so apparent after the bushes reach maturity. The demand for this fruit seems on the decline. Its peculiar pungent flavor and aroma are disagreeable to most native Americans, but when made into jellies or preserves it is distinctly good, and its various preparations are supposed to possess valuable medicinal properties.

Some years ago the late Shelby Reed, of western New York, sent me several samples of wild Currants and Gooseberries, natives of the great western plains of Colorado. These varied in color from black and red to yellow. They were of good size and very productive. Whether he attempted to improve or acclimate them at his home I do not know, but I consider the field a fine one for experiment, and well worthy the attention of those who have the time and inclination to enter it.

The Vegetable Garden.

CONTINUE to sow Snap Beans once a week in rows two to two and one-half feet apart. About the middle of the month sow French Etampes in rows eighteen inches apart and in a warm, sheltered spot; should these not be likely to ripen before frost comes, frames and sashes may be placed over them about the middle of September. Sow Bliss' Abundance and McLean's Advancer Peas in rows two feet apart; they will not need brush. Plant out Savoys, Cabbage and Cauliflower as ground becomes vacant. In localities where this planting will be too late Burpee's Extra Early Express Cabbage will yet form good hearts; it is a very quick-heading kind. Give Celery, either in the seed-bed or planted out, abundance of water; this is a plant which, from sowing till harvesting, should never know what drought means. Use rich land and mark it off into rows three to four and one-half feet apart, according as the Celery is needed for early or late use; if for early use it must be earthed up full in the rows, hence needs more room than if for late, when handling only is necessary. Sow a little Chervil in some odd corner for use in fall and to live over winter. Thin out Chicory plants to an inch or two apart in the rows. Cory was our best early Corn; sown late in May, it was ready for use by the middle of July. Marblehead was a few days later, but of better quality. It is too late for fresh plantings of Corn now. Egg plants are now swelling fruit. Do not let them suffer from drought and keep the potato beetles hand picked. A succession of Cucumbers may still be raised in frames. In the case of the vines out-of-doors, pick off all mature fruit, even if they are not wanted; by this means the old vines will continue longer in bearing. Scatter fresh tobacco stems under and about the vines to dispel aphides. Prevention is better than cure. Melons are now setting and swelling their fruit. Take pieces of boards, say four by six inches, and place one under each melon to keep it off the damp ground. Staves of old cement barrels are good for this purpose. Keep open pathways between the rows of hills for convenience in gathering; if the vines are allowed to grow together, we are apt

to tread upon and destroy them in gathering fruit, pulling out weeds, or in doing other work among them.

Sow Lettuces for succession and plant out a little every week. Some Endive may also now be sown for plants to be used in November. Endive is not in demand, if good Lettuces can be had, but full-grown plants of it can be easier kept in cold-frames in winter than mature Lettuces.

Keep seed Onions growing as long as possible. The ground after them will be in good time for Strawberries or Spinach. Potato and Top Onions and those raised from sets, also Garlic and Shallots, are now harvested. Tie them into bunches and hang them up, or crop them close and spread them out on the floor or shelves in some dry, airy building.

Get in a main crop of winter Beets. Sow in rows eighteen inches apart. Treat Turnips in the same way, only they may be sown a week or fortnight later than Beets. Some people like winter Radishes—that is, such sorts as Scarlet Chinese, which are grown into good sized roots, and gathered and stored in moistish sand in winter like Carrots or Turnips. Large roots are not desirable; those of about one and one-half to two inches in diameter are large enough. Sown about the 25th of August, we get capital roots for storing; in less favorable localities they should be sown ten days earlier. But they are not as desirable as the succulent French Breakfast and Wood's Frame, which can be kept growing in frames or green-houses during winter. Finish sowing winter Carrots; if sown later than the first week of August they are not likely to be large enough before frosty weather sets in. The Half-Long Red Stump-rooted is an excellent sort. Among Tomatoes, Farquhar's Faultless was our earliest to ripen this year, but it is a very uneven, deep-ribbed sort. Early King Humbert and Volunteer were about two days later than Faultless; the Humbert, although extremely prolific, has not the large size or round form of the beautiful Volunteer. Early Advance came next in point of earliness; then Acme, and then the other varieties all about the same time. G. C.

Long Island.

Some Floral Novelties.

Larkspur, Stock-Flowered Rosy Scarlet, is a new variety, with single, but often double, flowers, of a rose, rose-red or rose-pink shade. It is as free-growing and tree-blooming as any other annual Larkspur, and it comes true from seed, but while there is in this variety a new shade of color among these Larkspurs, we do not get in it anything very striking or of much importance.

Statice *superba* is an annual species from Turkestan, sent out this year. In habit and general appearance it somewhat resembles *S. Suworowii*, which appeared a few years ago. Its foliage is sinuately cut and lobed and produced in flat rosettes, while from the middle of these tufts arise much branched or plumose spikes of small, pale, rose-purple flowers. But, so far, it is neither as pretty nor as vigorous as *S. Suworowii*; at least, so it appears here, and the two species are growing together.

Drummond Phloxes have, of recent years, been considerably improved, especially in the increased size and brightness and variety in color of the flowers; this large-flowered race is now known as grandiflora. Florists have succeeded in doubling the flowers of a white, and also of a red, variety, but the doubling is only semi-double, and, as regards the beauty of the flowers, it is more of an injury than a benefit. The double white comes fairly true from seed, but of the double red only a small percentage come double. Under the name of grandiflora fimbriata, there is a purple-flowered variety, with fimbriated or notched edges and a narrow edging of white, but, except as a novelty, it is of little value; the color is too poor. Evolved from this fimbriated flower and now distributed under the name of cuspidata, comes an extraordinary flower; each lobe of the corolla is furnished with one long, narrow, pointed segment and two lesser ones, and all bordered with a narrow, white band. But here again the color is only dark violet-purple. It is also distributed under the name of Star of Quecledenburg. Its singular appearance makes it a striking novelty, but, so far as beauty, showiness or general usefulness is concerned, it is not as good as the common, plain-flowered varieties. A large proportion of the plants come true from seed. There is also a dwarf race of Drummond Phloxes that are indispensable in their way; they are used in beds and borders with much neatness, but their greatest usefulness is as pot plants, for which purpose they are admirably adapted and largely grown by some florists. H. F.

Olive Tree in the Garden of Gethsemane.

Orchids in Bloom.—*Lalia callistoglossa*.—This Orchid is so named from its gorgeous lip, which rivals even that of its near relative, *L. bella*. In shape it is much like that of *L. purpurata*, with a fine undulated margin. The color is a rich purple shaded to maroon, the pale yellow throat being streaked with purple. It is the result of intercrossing *Lalia purpurata* with *Cattleya Gigas*. In growth it much resembles its seed parent. The flower, appearing when the growth is only half matured, is large, of a delicate rose color and delightfully fragrant. This hybrid is as yet very rare, but like the majority of hybrids, is so free growing that it cannot fail to be moderately plentiful in a few years. A warm house, with plenty of water while in active growth, should be given it, with only sufficient water to keep the bulbs from shriveling during the winter, and like all other members of this genus the roots should be allowed to ramble at will.

Calogyne pandurata.—This curious Orchid is now in flower with us; the remarkable combination of black and green in the flowers being so rare render it a very interesting species.

The racemes bear eight to twelve pale green flowers about three inches across, the pandurate lip being irregularly streaked with black. It is an extremely free growing kind, often flowering twice in one year, and should be kept in a warm house all the time and liberally supplied with water. Baskets are best suited for it, filled with charcoal, and very little peat and moss, as it dislikes much material around its roots. It is a native of Borneo.

Kenwood, N. Y.

F. Goldring.

The Olive Tree.

THE Olive tree has in all ages been celebrated as a special gift of Heaven and as the emblem of peace and plenty. The wild and the cultivated Olive were mentioned in the earliest books written in the Hebrew language; it was one of the trees of the promised land of Canaan; and it was a branch of this tree which the dove sent out by Noah brought back into

the ark. The Olive was cultivated by the ancient Egyptians, and by the Greeks during several centuries before the Christian era. They brought it probably from the southern part of Asia Minor, where extensive forests of the wild Olive still exist; at least this is the opinion of M. Alphonse De Candolle, who, in his "*Origine des Plantes Cultivées*," has collected what is known of the early history of the Olive tree. Whatever region may claim the honor of being the first home of the Olive, it has now become widely distributed, primarily by man, and secondarily, and very considerably, no doubt, by the action of birds, being found in a more or less wild state from the drier regions of India through the Levant and the whole of the Mediterranean Basin to Portugal, Morocco, Madeira and the Canary Islands, where De Candolle doubtfully suggests it might have been carried by the Phœnicians.

The Olive (*Olea Europæa*) is a tree with a short, stout trunk, three to six feet, or even more, in diameter, divided a few feet from the ground into a number of large branches. It reaches, under favorable conditions, a height of forty or fifty feet. The bark, which is gray, is quite smooth on the branches and on the trunks of young trees, becoming rough and deeply cleft on old trees. The leaves are opposite, persistent, coriaceous, lanceolate-acuminate, less than an inch long on the wild plants, an inch and a half to two inches and a half long on some of the cultivated varieties. They are entire, dark green on the upper, and covered with a pale tomentum on the lower surface.

The small white flowers appear in axillary racemes equaling the leaves in length. The ovoid fruit of the wild plant hardly exceeds a red currant in size, while in some of the cultivated varieties it is considerably more than an inch long. Not more than one or two fruits develop then from each raceme, although in the case of the wild plant there are often six, or even more. The fruit, which in most of the best varieties is black when ripe, is covered with a smooth and shining skin, covering a soft green pulp filled with oil, and adhering to the hard, oval, oblong stone, pointed at both ends, and consisting usually of a single cell by abortion, and containing a single oily seed. As might have been expected in the case of a plant carefully cultivated for centuries in different countries, and by different races of men, many varieties of the Olive have been developed. No less than thirty-two such varieties are described systematically in the *Nouveau Duhamel* (v., p. 70, t. 25 to 32), where by far the best account of this tree, its economic uses and the methods employed for the preparation of its products, may be found.

The Olive flourishes in regions of small rainfall and in the most arid and barren soil, preferring that which is strongly impregnated with lime; but it will not support more than a few degrees of frost. Henry Laurens, a merchant of Charleston, in South Carolina, introduced the Olive into America about the year 1755. It is recorded that his trees bore fruit, "which was prepared and pickled to equal those imported." There are fine Olive trees on the southern end of Cumberland Island, off the Georgia coast, which bear fruit every year, and which must be nearly a century old. The climate, however, of the southern Gulf States, is not well suited to this tree, but on the Pacific coast in southern California, where it has grown for more than a century about some of the old Catholic missions, it is perfectly at home, and the cultivation of the Olive and the manufacture of Olive oil is one of the most promising of the younger California industries. The ancient Olive tree, which is illustrated upon page 284 of this issue, is of peculiar interest. It is a venerable and characteristic specimen of a tree which has few rivals in its usefulness to the human race, while individually it is one of the best known and most interesting trees in the world. It stands in the Garden of Gethsemane, at the base of the Mount of Olives, near Jerusalem, and is known as "The Tree of Agony," being popularly supposed to have witnessed the vigil of the Saviour.

Notes From the Arnold Arboretum.

"SHRUB," or Strawberry Bush, as *Calycanthus floridus* is commonly called, was once considered an essential feature of every old-fashioned garden; and its fragrant, dark brown flowers are perhaps known to as many people as those of any American shrub. There are, however, two other species of this genus with the same brown and fragrant flowers, which are not often cultivated, although they are harder than *C. fragrans*, which in severe winters is often killed down to the ground; and which flowers here early in June, or some time earlier than *C. laevigatus* and *C. glaucus*, which are now in bloom here. The former has large oval leaves, gradually acuminate at the apex, green on both sides, and only slightly rugose on the upper surface. In *C. glaucus* the leaves are narrower, and considerably larger than in the other species, pale below, with a few hairs along the mid-rib, and rugose on the upper surface. It has large flowers, and rigid, upright branches, which are sometimes six or eight feet high. The three species are natives of the Alleghany region from Virginia to Tennessee and Georgia, *C. laevigatus* extending as far north as southern Pennsylvania. Gardeners have too long neglected this last species, which is one of the most desirable of all hardy summer-flowering shrubs.

The shrubby Cinque-foil (*Potentilla fruticosa*) is one of the most widely distributed plants of the north temperate zone, being found through the northern portions of North America, in many parts of central and northern Europe, and through central and Russian Asia to Japan. It is a dwarf and branching shrub, two to three feet high, an inhabitant of low ground, and just now a conspicuous object, with its large, terminal, pale yellow flowers. The leaves are pinnate, with five to seven pairs of crowded, pale, silky leaflets. The short, flowering branches die down annually, but the base of the stems is truly woody. This has been found a useful plant in the Arboretum for forming masses of low shrubbery among trees, as it spreads rapidly from underground shoots, soon taking complete possession of the ground. It may, however, become, like *Genista tinctoria*, a dangerous weed if allowed to spread indiscriminately. It has indeed already overrun and utterly ruined considerable areas of mowing land in some parts of Berkshire County, in this State, and in Connecticut, where farmers find it almost impossible to eradicate this plant, and where it is known as "Hardhack." *Potentilla tridentata* is another woody species now in flower. It is found sparingly on the New England coast north of Cape Cod, on the coast of the Great Lakes and upon the summits of some of the high mountains of eastern North America. It is a low, spreading plant, only a few inches high, with handsome dark green and shining, palmate leaves, with three wedge-oblong divisions, coarsely three-toothed at the apex, and loose cymes of white flowers, half an inch across. This is an excellent plant for the margins of the rock-garden, as it remains a long time in flower, while its foliage is ornamental throughout the season.

Among the Leguminous plants now in flower, *Amorpha canescens*, the Lead Plant of the western prairies, is by far the handsomest and best worth notice. It is a spreading bush, two or three feet high, softly canescent and hoary throughout, with pinnate leaves, composed of fifteen to twenty-four pairs of minute leaflets and spikes of handsome bright blue flowers aggregated in a terminal sessile panicle. It is found on dry and sandy prairies from the Red River of the North to Texas, and its presence is popularly supposed to indicate the presence of lead-ore. It is an admirable and very hardy plant in cultivation, remaining in bloom during several weeks. The Lead Plant is rarely seen in gardens, however, although one of the first of our western plants known to botanists; and, although it was introduced into England as early as 1812, no figure of it was published until 1882, when it appeared in the *Botanical Magazine* (t. 6618). In the same volume of this Magazine appears the figure of another plant of the Pea Family, *Lespedeza bicolor*, now in flower. It is a native of north-eastern Asia from Manchuria and northern China and Japan, and is considered one of the most beautiful of the hardy shrubs introduced of late years into cultivation. *Lespedeza bicolor* is a slender, leafy shrub, four or five feet high, with slender, elongated and very graceful branches, three-foliolate leaves on long, slender petioles, with oblong, obovate leaflets, and axillary or rarely terminal drooping or sub-erect racemes of showy rose-colored flowers, an inch long, which are described as sometimes white or violet. This is a perfectly hardy plant and remains a long time in flower.

A Heath-like plant, *Dabaccia polifolia*, is in flower. It is a dwarf shrub with slender ascending branches one or two feet high, covered with small, narrow leaves, which are dark

green on the upper surface, and snowy white below, and large white, purple or rose-colored nodding flowers arranged in loose terminal racemes. "St. Dabeoc's Heath" is a native of south-western Europe, where it sometimes covers barren and gravelly wastes; and it is found in one or two stations in Ireland. Here it is a delicate and not very hardy plant requiring careful protection in winter and frequent renewal; and in spite of its beauty it can hardly be recommended for general cultivation in the climate of the eastern United States.

Rhamnus Frangula is a widely distributed European and North Asian plant, closely related to the Carolina Buckthorn of our Middle and Southern States. It is a tall, erect, unarmed shrub, growing to a height of eight or ten feet, with slender branches, handsome, glossy, pale green foliage, and small, axillary, yellow flowers, which are followed by rather conspicuous fruit, which is at first green, then bright red, and finally, when fully ripe, quite black. This plant continues to produce flowers in great profusion all summer long, and is covered during several months with flowers and with fruit in all stages of development, a peculiarity which, as well as its handsome foliage and entire hardiness, should give this Buckthorn a place in collections of deciduous shrubs. The wood is known in England as black dogwood, and in common with that of other species of the genus, has a considerable employment in the manufacture of gunpowder. Another plant which flowers here from the middle of July until the coming of frost, and which produces flowers and ripe fruit simultaneously, is the Chinese Lycium (*L. Chinense*), near relative of the well known and familiar Matrimony Vine of all old-fashioned gardens (*L. Europaum*). It has long, pendulous, or prostrate, armed branches, ten or twelve feet long, ovate-acute, dark green leaves, rather large pale purple flowers, and abundant, showy, bright scarlet, oval or oblong fruit, which is nearly an inch in length. This is a free growing and very hardy plant, admirably suited to train upon pillars or over trellises, and in every way more showy than the European Matrimony Vine.

Attention has been directed in an earlier issue of these notes to the great value of *Spiraea sorbifolia* as an ornamental plant; mention must now be made of a variety of that plant cultivated here under the name of *S. Tobolskia*, a name not referred to by Maximowicz in his monograph of *Spiraea*, and here applied to a plant probably of garden origin, and which only differs from *S. sorbifolia* in its much smaller panicles of flowers, and in the fact that it blooms from two to three weeks later. It is an equally hardy and desirable plant.

Aralia hispida, the Wild Elder of northern woods, may perhaps be considered a shrub, as the base of the stems are truly woody. It is a useful plant, largely grown in the Arboretum for covering the ground under trees and larger shrubs, for which purpose its habit of spreading rapidly by means of underground shoots well adapts it. It deserves notice, too, as a purely ornamental plant; the foliage is bold, the large, compound corymbs, composed of umbels of yellow flowers, make it conspicuous during the early weeks of July, and these are followed in autumn by showy, deep purple fruit.

Rosa setigera, the Michigan or Prairie Rose, is in flower. It is a widely distributed species, being found from Ontario and Wisconsin to Texas, South Carolina and Florida; and the only American Rose with climbing stems. It is the origin of the Queen of the Prairies, Baltimore Belle, and other double flowered climbing Roses, and in its single state is one of the most beautiful of our climbing plants, with broad and handsome foliage, and broad, flat corymbs of large flowers, which are sometimes nearly three inches across, and deep rose color when first expanded, but turning nearly white before fading. The Prairie Rose requires rich, deep soil and generous treatment to develop its greatest beauties, but when well grown it surpasses in beauty any of its progeny. 7.

July 21st.

The Forest.

The White Pine in Great Britain.

Mr. A. D. Webster, in a recent issue of *The Garden*, makes the following interesting statements in regard to the White Pine (*Pinus Strobus*) in England, called forth by Dr. Mayr's article upon this tree in the first number of GARDEN AND FOREST. They are all the more interesting because it is now very generally believed by English planters and nurserymen that this tree does not flourish in that country, where for some reason or other it is certainly much less frequently seen than on the continent of Europe.

"Next to the Corsican Pine (*P. Laricio*), I consider the White,

or Weymouth Pine, whether as an ornamental tree or for economic planting, the most valuable of the many Pines that have yet found their way into this country. The woods at Gwydyr Castle, in North Wales, and of many other places that I could name, amply substantiate Mr. Mayr's remarks as to the great value of the Weymouth Pine as a rapid timber-producer, and likewise as to its yielding under similar conditions to the Scotch Fir (*P. sylvestris*) a far greater amount of wood than that valuable and much-cherished tree. Let us look at these Gwydyr specimens and compare their rate of growth and bulk of timber with that of the Scotch Firs with which they are associated. Unfortunately, we do not know when these trees were planted, but one thing is pretty conclusive, that the whole wood, which crowns a shingly-soiled hill in the romantic and picturesque Conway Vale, was planted at or about the same time. The Weymouth Pines are now what might in truth be termed giant specimens, for I am under the mark in stating that the average height is fully 90 feet, and the girth of the flag-pole-like stems between eight feet and nine feet at a yard from the ground. Straight as ship masts describes well their appearance, they being smooth, nicely tapering, and destitute of branches for about three-fourths of their height. About the biggest Scotch Fir in the same wood is between seventy feet and eighty feet in height and with a bole fully seven feet in girth. Were we to touch on cubical contents, the differences in these two species of Pine would hardly be credited, and should any one feel inclined to doubt the genuineness of these statements, Mr. McIntyre, agent on this historic Old Welsh estate, will gladly vouch for their accuracy. The soil at Gwydyr is of a rocky, shingly nature, largely intermixed with the richest of vegetable refuse, fairly moist at all times, but without stagnant water. Situation not sheltered, yet not fully exposed. On another estate in Cambria I have measured specimens of the Weymouth Pine 57 feet in height, and with stems fully 50 inches in girth at a yard up, the trees being only thirty-one years old.

"At 1,200 feet above the level of the sea, at Strathkyle, in Ross-shire, the Weymouth, in conjunction with the Corsican and several other species, is doing well and making rapid progress. Then look at the Longleaf trees, which are fully ninety feet in height, not long drawn-up poles, but huge stems fully eight feet at breast high. I will say no more about how it succeeds in this country, for that it does well I am quite convinced.

"But some may ask, What about the timber? for plenty of foreign trees do fairly well in this country, and yet are valueless as timber-producers. I also know something of this, and am able to speak of it in terms of the highest praise.

"The timber, judging from the specimens I have had a chance of converting into boards, is of exceptional quality, being clean and very easily worked, of a desirable color, and, from experiments instituted five years ago, of a lasting nature."

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—I should be grateful for some advice as to the best plants and shrubs for the adornment of a small place at Falmouth, on the southern extremity of Cape Cod. Excepting a strip of the original ground, the land has been reclaimed from a salt marsh. The place seems too limited to justify the calling in of a professional landscape gardener, but I am inclined to spare no pains to make the planting effective. F.

Falmouth, Mass.

[Our correspondent, in common with nine hundred and ninety-nine persons in every one thousand, who want to treat a small piece of ground to the best advantage, makes the mistake of thinking that "the place seems too limited to call in the aid of the professional landscape gardener." A trained artist is needed to develop the possibilities of beauty, convenience and usefulness in a small as well as in a large piece of ground, and his knowledge and ingenuity may be more seriously taxed to make the most of a plot of ground containing a few hundred square feet than of a park of hundreds of acres. It is, of course, quite outside our editorial duties or aims to give specific instructions or advice about laying out or planting particular places. Such advice to be of any practical value must be based upon exact knowledge not only of local conditions and surroundings, but of the taste and wishes of the proprietor in regard to the character of his place and of the

amount of money he is able or willing to spend on it. It may be said generally, however, that this particular location, in common with many others on the shores of Cape Cod and at other points on the New England coast, is exceedingly exposed to high, cold winds, and that the soil is thin and light, and therefore seriously affected by droughts in all but exceptional seasons. Trees, even if they could be made to grow at all in a position so near the shore, would not be very satisfactory, and a lawn of close-cut turf had better not be attempted, as it would be pretty sure to be burned brown all summer long, and to be anything but an object of beauty. Much of the New England coast-region is unsuited for gardening, as that term is popularly understood, an art which finds expression in trim lawns and in beds of plants with colored foliage. The art of true gardening consists in making the most of natural conditions, and not in attempting the impossible or the unnatural for the sake of imitating the fashions of other countries. A large part of the region in question is covered with broad expanses of shrubbery composed of dwarf Plums and Viburnums, Huckleberries and Blueberries, Sumach and Wild Roses, Bayberry, Sweet Fern, Inkberry, Smilax and other dwarf shrubs, combined together in natural masses unsurpassed in their peculiar way in any other part of the world, and which are bright and fresh from the early days of spring until the autumn frosts make them blaze with new beauty. It is from among these native plants of New England that the material for the embellishment of the grounds of New England sea-shore homes should be selected, and the combinations of these plants which Nature makes are those which must be studied, if the best which these homes can be made to express in beauty is to be attained. Let any one compare a mass of the native shrubbery sweeping down to the shore on Mount Desert, or on the southern shores of Cape Cod, with the ordinary improved grounds which may be seen about the villas in these places, with brown lawns and sandy walks, with here and there a stunted Scotch Pine or a Cut-leaved Birch, and with beds half filled with forlorn Geraniums or dried-up Coleus, and he will see that large expenditures of money, when not directed by adequate knowledge and taste, may, in attempts at gardening, expel from a spot naturally beautiful all its native charms, without supplying anything in their place—either artistic or pleasing.—Ed.]

To the Editor of GARDEN AND FOREST:

Sir.—I notice in your issue of June 27th that our company is credited with the introduction of that beautiful Japanese shrub, *Symplocos paniculatus*. Will you allow me to state that Mr. Thomas Hogg was the introducer, and we only the disseminators. Mr. Hogg brought from Japan so many beautiful things which have produced no profit, either to himself or to us, that all due credit should be accorded to him. I am the more anxious that this should be done here, since I have never been able to get the American introducers of new plants from Japan recognized in English periodicals. I sent a painting of the beautiful *Magnolia parviflora* to an English paper, with a careful description taken from a flower before me, and naming Mr. Hogg as the introducer. This description was ignored, a very meagre note took its place; and while we were recognized as the senders of the painting, Mr. Hogg was entirely ignored as the introducer. This experience was repeated in the case of the Hydrangea named for him, and in the case of the Japan Maples, the whole collection of which was sent to us by Mr. Hogg. I may add Dr. Hall was treated in the same way.

Flushing, L. I.

Sam'l B. Parsons.

To the Editor of GARDEN AND FOREST:

Sir.—Throughout Minnesota and Dakota, along the north side of railway embankments, the south side of railway cuts, and on breakings that have lain a year or more, little trees come up and grow until weeds and grass form fuel enough for a fire to kill them.

On the prairies and plains these seedlings are not abundant, but still they do come up.

I believe that if fires could be kept from running over the land, with occasional tree claims to furnish plenty of seed, trees and shrubs would soon come in and improve this country very much.

Mandan, Dakota, July 13th.

H. B. A.

To the Editor of GARDEN AND FOREST:

Sir.—Reference was made in GARDEN AND FOREST, July 18th, to Locust and Elder flowers being used in Europe as delicacies for the table. Of the Locust I cannot speak from experience, but I can of the Elder. The flowers of the common Elder, stripped from the stems, are excellent ingredients in waffles or "flannel" cakes. These flowers add a delicious flavor to the cakes and are considered healthful. People who are not quite æsthetic enough to live on the perfume of Lilies, may find in Elder blooms a seasonable diet.

H. V. A.

Palmyra, N. J.

Periodical Literature.

In the *Popular Science Monthly* for July is an article by Mr. Grant Allen, even more attractive than the one on "The Bread-fruit of the Desert" to which we recently called our readers' attention. This time his subject is "Gourds and Bottles" while his place of observation is again the north coast of Africa. The great family of Gourds (*Cucurbitaceæ*) is known to us in this country through our cultivated Melons, Pumpkins and Cucumbers, and through a few wild species none of which produces a fruit of any great size. But the fruit of the true Gourds of which Mr. Allen writes, is familiar not only through imported dried specimens made to serve as bottles, but through the innumerable pottery and porcelain imitations of these bottles which are so characteristic of the art of every southern and eastern nation. Part of Mr. Allen's article is taken up with a discussion of the way in which, after having once learned to make vessels of the dried Gourds themselves, men learned, first to strengthen them with a coating of baked clay and then to use the clay by itself while keeping the original shapes; and in showing how all the varieties of Gourd-like shapes we know may have sprung from direct imitation, since the Gourd naturally assumes many diverse forms and may be made to assume a still greater diversity by being constricted during its growth. But much space is also given to a description of the habits and manners of growth of the plants, and of the different ways by which cross-fertilization through insect agency is achieved in different species.

In the same number of the *Popular Science Monthly* Professor Byron D. Halsted writes of "Botany as it May be Taught" in a manner so sensible and suggestive that his article ought to attract the attention of all teachers and students in this branch of knowledge. Its value is vastly increased, of course, by the fact that he explains methods which are not merely theoretical, but which he has successfully put in practice with large classes of young men and women in the State Agricultural College of Iowa. A third article which may be noted in this magazine is Dr. Manly Miles's on "Lines of Progress in Agriculture," while among the minor contributions is an interesting one on "Flower Farming" for the production of essences in the south of France, and another on the manufacture of India-paper from the fibres of Hemp, Mulberry-bark and similar substances.

Notes.

The death is announced of Giuseppe Inzenga, a well known authority on Fungi, who was Professor at the University of Palermo.

Mr. David Allan, gardener to R. M. Pratt, Esq., Watertown, Mass., has a number of fine plants of the showy *Disa grandiflora* in full bloom.

A single plant of *Ampelopsis tricuspidata*, on Camden Street, Boston, covers completely the front of a three-story block of houses for a distance of one hundred and twenty-five feet.

From Newport are now coming Hydrangeas with blue flowers and Sweet Peas of the Butterfly variety with lilac edgings. These are now extensively used by florists of this city in choice designs.

In the absence of White Carnations, Asters are largely used by the Boston florists, during the summer months, in making up designs. One large grower averages, at the present time, three thousand Aster-blooms a day.

Mr. John N. May, the well-known Rose-grower of Summit, New Jersey, is not prepossessed in favor of the Rose, Mrs. John Laing, owing to the muddy color of its blooms after they have been cut twelve hours or so. Nevertheless, he is devoting his largest house to its cultivation, and will give it a fair trial.

A dozen plants of the new *Cypripedium bellatulum*, recently described in this journal, were exhibited by the Messrs. Low at a late London flower show. Every one of them bristled with flowers, tending to prove the floriferous quality claimed for the plant by its introducer.

A statue is to be erected to the memory of the French botanist, Planchon, in the town of Ganges, not far from Montpellier, and in the centre of a Grape growing region, once devastated by the Phylloxera, to whose investigation and to the study of the Vine he largely devoted the last years of his useful life.

The Royal Horticultural Society of London will give no more certificates for new varieties of tuberous Begonias. The committee holds that something like perfection has been reached in this direction, and that hereafter not an individual variety, but the particular strain of varieties, should be commended.

The remarkable specimen of the new variety of *Cattleya Gigas*, described in another column, has been added to the rich collection of F. L. Ames, Esq. Although it had been in bloom quite three weeks when it was sent to North Easton, the flowers were in perfect condition when it arrived at its new home.

Six thousand bushels is the average annual crop of pears yielded by three of the larger orchards in Essex County, New Jersey. This year the crop will hardly reach two hundred bushels. The failure is attributed, by some fruit-growers, to unfavorable weather when the trees were in bloom, which prevented the proper fertilization of the ovule.

Some idea of the dependence of Great Britain upon French gardeners will be gained from the fact, published in the *Journal of Horticulture*, that during the year 1885 there were shipped to England from the little port of Roscoff, in Brittany, 11,107 tons of Potatoes; 4,060 tons of Onions; 4,000 tons of Cauliflowers; 1,800 tons of Artichokes.

Probably the largest specimen of *Todea barbara*, a Fern with a thick, woody stem, peculiar to Cape Colony, Australia and New Zealand, ever sent to Europe, has recently been received at the Jardin des Plantes in Paris. It weighs nearly 600 pounds, and the stem, from which spring sixty clusters of fronds, is four feet high, six feet long, and nearly four feet wide. It is said to be in good condition.

It is claimed that the first exhibition devoted exclusively to the Chrysanthemum was held at Toulouse, and that more than 6,400 flowering specimens of this popular plant were collected at the exhibition which took place in that city three years ago. An exhibition of these plants, under the auspices of the *Société d'Horticulture de la Haute-Garonne*, will be held there this year from the 15th to the 18th of November.

In the Grass and Forage Garden at the Storrs' School Agricultural Experiment Station, Connecticut, are growing seventy-five species and varieties of grasses, legumes and other fodder plants; besides this, a number of sods have been set out. The farmers of the State are invited to send samples of sod from old meadows and pastures, six inches square, with a view to test the different grasses from all parts of the State.

A letter to a daily paper appealing for contributions to the New York Flower Mission, the work of which was recently described in our columns, states that on a single day last month 11,425 bunches of flowers were distributed among the poor and sick. Another centre for the reception and distribution of flowers has been opened at Police Headquarters, 303 Mulberry Street. Wherever gifts may be sent it is desirable that they should be enclosed in old boxes or baskets which need not be returned. It is hardly necessary to add that fruits will be as welcome as flowers.

On the day of the late Emperor Frederick's funeral (June 18th), the hundredth anniversary of the birth of the botanist Karl Sigismund Kunth was celebrated in the Jerusalem Church-yard at Berlin by the Botanical Association of the Province of Brandenburg. Kunth's reputation rests upon his labors in describing the plants collected by Alexander von Humboldt and Aimé Bonpland, upon the examination of the Passalagua collection of vegetable remains from Egyptian tombs, and especially upon his classical "*Enumeratio Plantarum*." Kunth was well known in his life-time as a student of garden plants and for many years was Professor and Vice-Director at the Botanical Garden in Berlin. His death occurred in the year 1850.

The *Revue Horticole* calls attention to the fact that the formal arrangement of plants has been abandoned in the flower-beds seen this year in the city of Paris. Such beds are now usually surrounded with a formal row of plants of one variety; the remainder, except in the case where the bed is divided into compartments by means of lines of color, being entirely filled with various combinations of flowering or foliage plants, grouped naturally and without formal arrangement. Some of the combinations of the plants, made by the Parisian gardeners, are far more attractive than the formal ribbon-border style of arrangement so universal in the United States and in England.

A correspondent of a San Francisco paper in Paarl, in Cape Colony, says, that the Colony annually exports about 50,000 cases of Everlasting Flowers, worth some twenty dollars a case, half of which go direct to New York and Boston. The flowers are gathered by the Kaffirs, chiefly in the Drakenstein Mountains, about fifty miles from Cape Town, and are brought to the country storekeepers, who dry them in long sheds, from the roof of which they are suspended in bunches in order that the warm wind may pass freely among them. The Kaffirs go out in families in the gathering season, and the women and children do most of the work, which is by no means easy, as they must follow unfrequented paths, and their half-naked bodies are sadly bruised by the stones and thorny bushes among which the plants are found. A certain amount of actual danger is also involved in the work, as life is often risked to obtain choice specimens growing on the verge of precipices.

A telegraph wire is the last thing one would expect to support vegetation of any kind; yet a traveler in Brazil writes to a German horticultural journal describing a crop of Mistletoe which he found clothing the wires not far from Rio Janeiro. At a distance, he says, the wires appeared fringed with what he supposed were the leavings of a recent flood. But a perception of their height soon removed this idea, and upon examination the fringe proved to be composed of thousands of little Mistletoes, firmly fixed to the wires from which they depended. Many species of this family flourish in Brazil, and some of them, called "Bird-weeds" by the people, thickly infest fruit-trees and other cultivated plants and bear large berries which are greedily devoured by birds. These seeds are deposited on the telegraph wires in the birds' droppings and quickly take root, and although the plants perish, naturally, before very long, they are succeeded by others, and the curious Mistletoe fringe is perpetuated.

A private letter from the chairman of the California Forestry Commission speaks encouragingly of the work already accomplished by the commission. Important additions to the forest map have been completed during the present season; the nurseries established a few months ago by the commission, under the charge of Mr. Thomas H. Douglas, already contain 300,000 young forest trees for distribution through the State, while lands valued at from \$60,000 to \$80,000 have been presented to the commissioners by private parties to enable them to inaugurate and carry on experiments in forest planting. Satisfactory progress has been made also in stopping the stealing of timber from Government and State lands, and the setting of forest fires, which have long threatened the very existence of the California mountain forests. The efforts of the commission have had, however, the result of forcing lumbermen and speculators to take up Government timber lands, and the sales of such lands during the last year are unprecedented in amount.

At a recent Saturday exhibition (July 28th) of the Massachusetts Horticultural Society, a collection of Achimenes shown by Mr. N. T. Kidder, of Milton, attracted much attention. Better grown, cleaner and better flowered plants have probably never been seen in this country. The collection contained specimens of Mauve Queen, with very large flowers of great substance, and the handsomest variety shown, although not so covered with flowers down to the base of the stems as some others, Carl Schurz, Grandiflora, Longiflora, Bronzoni, Dazzle, Admiration and Eclipse. Achimenes, although they are less commonly seen here than they were a few years ago, are excellent plants for the summer decoration of green-houses and conservatories. To the same exhibition a splendid plant of *Sobralia macrantha*, one of the noblest of terrestrial Orchids, was sent from the garden of Mr. John L. Gardner. It was more than seven feet high, with a dozen and a half of its lovely, great, purple, aromatic flowers expanded. This is one of the few Orchids which combines stately habit, handsome and abundant foliage, and showy flowers.

Work for the Experiment Stations.

PLANT breeding bears the same relation to horticulture that stock breeding does to animal husbandry. The advance of modern horticulture is most marked in the increased number and improved quality of varieties, and in this direction lies the brightest hope of future progress. The study of soils is the task of the agricultural chemist. The study of plant diseases falls naturally to the botanist, and that of insects to the entomologist. But the study of plant development is the legitimate field of the horticulturist, and here he may expect his highest achievement.

And yet the systematic pursuit of plant breeding is scarcely compatible with practical horticulture. Its results are too slow, too costly and too uncertain to offer pecuniary reward, yet the labor itself requires a high degree of scientific knowledge and skill. It is just here that the Experiment Stations should come to our aid. They should develop a new class of specialists, whose entire time should be devoted to the work of plant improvement. This labor can undoubtedly be best advanced by judicious cross-fertilization, and the art of crossing should be regarded as the first requisite in this new profession. The desultory and unsystematic, and even haphazard, efforts that have been made in this field of experiment in the past, have yielded such truly valuable results that we are abundantly justified in hoping for greater results, from the pursuit of cross-fertilization in a thoroughly scientific manner.

Many are now looking to our Experiment Stations for achievements in this very field, and indeed some success has already been attained in it. But the vast amount of time required in the work of cross-breeding, when done systematically, makes it impossible for the regular horticulturist of the station to accomplish much in this direction. Those who have not attempted it have little idea how tedious and trying is the actual work in this direction. A half day's patient labor will often yield but a score or two of pollenized flowers. Many of these may fail. But with those which live the labor has but just begun. The fruits, which contain the coveted seeds, must be carefully

watched throughout the season in order that they may not be lost. The following year the plants must be grown, their characters noted and selections made. It will often happen that, after a generation or two, the progeny of a single cross will have become so extensive and will offer so many promising lines for selection, that it will prove no small undertaking to keep informed of its current history, and the horticulturist who has much other experimental work on hand will be tempted to give up in despair.

A moment's thought will satisfy any one that a specialist at cross-fertilization need never lack for work—at least not after the first season. Different plants are in blossom at various times from early spring until autumn. Then there is the growing of the crossed plants, with the careful study of their characters, that those worthy of further trial may be selected. In order to possess the ability to make such selections wisely, the workman must be thoroughly conversant with existing varieties. This would require much patient observation and study. The winter season could be profitably spent in writing out the results and studying the records of what others have accomplished in the same field. With a green-house at command, much could be done to supplement the summer's work.

It is to be hoped that the directors of some of our Experiment Stations will appreciate this opportunity that lies open in the department of horticulture, and will make provision for a specialist of the kind here pointed out. But the mistake must not be made of supposing that any man who chooses to apply is competent for the position. On the contrary, it is a labor in which few men can be expected to succeed. It demands a considerable knowledge of botany, a thorough knowledge of horticultural varieties, and the ability to read accurately French and German literature. But most important of all, it requires a man who has a genuine love for the work, without which success in experimentation is quite impossible.

Notes from a French Garden.

The following extracts from a personal letter lately received by the editor of this journal from M. Charles Naudin, director of the Gardens of the Villa Thuret in the south of France, are of general interest:

"We have had a very severe winter in Provence; the cold has lasted much later in the spring than usual, and many plants have suffered in consequence; but with the month of May the heat returned, and many young trees, Eucalypti and others, which I feared were entirely dead, now show signs of life again. Such severe tests have their uses, as they establish the hardiness of plants, which otherwise might not have been thought capable of supporting our climate. You will be glad to hear, perhaps, that the gigantic *Yucca filifera** flowered here profusely during the month of May. Its enormous panicle of flowers, more than three feet long, descending in a white cascade from the top of the plant, was the admiration of all who saw it. We have five well-grown specimens of this remarkable *Yucca* in the garden here, and among them there are one or two which flower every year. *Yucca Treculiana* and *Y. Draconis*, which almost rival it in size and beauty, also flower here every year.

"You sent me a few years ago seeds of *Heteromeles arbutifolia*†. They grew well and the young trees are now in flower. It is a valuable addition to our southern gardens. The *Olneya Tesota*, the seed of which was sown a couple of months ago, are doing well, too. I have sent the seeds of this interesting tree to a large number of gardeners in southern France and in Algeria.

"*Nothoscordum fragrans*, an American plant, is now naturalized in the entire Mediterranean Basin; it abounds in this garden, where it propagates itself; and what is still more remarkable, this plant is now completely naturalized in Mauritius and in the Island of Bourbon, whence bulbs have been sent me under the name of *Milla Borbonica*. It is used there as a vegetable.

"I have lately received from Bolivia seeds and tubers of a

* See GARDEN AND FOREST, pages 78 and 79, Figures 13 and 14.

† [A small evergreen tree of the Rose Family peculiar to the California coast, where, in the autumn and winter months, when covered with its handsome red fruit, it makes a conspicuous object.—Ed.]

new species (?) or variety (?) of Potato, under the name of *Solanum Pureka*. The tubers, which are said to possess an excellent flavor, are smaller than those of the ordinary cultivated Potato and their shape is peculiar. The plant barely differs, however, in habit and in its flowers from *Solanum tuberosum*. Is it a variety or a species? And, after all, what is a species for the botanist of to-day? The conception of specific limitation becomes confused in proportion as the knowledge of natural science increases. And this remark is applicable certainly to the different plants of the genus *Bahmeria* (China Grass, Ramie). We cultivate here, and both are now in flower, *B. tenacissima* and *B. nivea*; while there is another species (?) here quite unlike either of them. And I learn, by a letter just received from the botanist Balanga, now in Tonquin, that there are in that country several species of *Bahmeria*, some cultivated and others wild, from which the fibre is extracted. I believe that there are still important discoveries to make in this genus of *Urticaceae*.

"While there are some North American trees which adapt themselves perfectly to our Mediterranean climate, there are others which cannot be made to grow here. This, for example, is the case with *Carya myristicaformis*, of which you sent me nuts four or five years ago. The plants, which are not three feet high yet, are alive, but they grow with a slowness which is discouraging, and the leaves are more yellow than green. This perhaps is the effect of the soil rather than of the climate. Some of the other Hickories do a little better here.

"Our success with a Bolivian plant, *Mutisia viciaefolia*, which is considered a specific against pulmonary complaints, is certainly astonishing. This curious Composite—which might, judged by its foliage, be mistaken for one of the Pea Family—has proved perfectly hardy here, passing the winter without protection and flowering freely, and, apart from its supposed economic properties, it is an interesting ornamental plant. It will certainly succeed in your Southern States—Virginia, Carolina, Florida, etc.—and if really a remedy for consumption, its introduction there will be a matter of great importance.

"I am trying now, for the third time, to cultivate *Lepedeza striata*, which heretofore has not succeeded in Provence. It is probable that the climate here is too dry and too hot for it. I have sent seeds to Brittany and into the south-west of France, where perhaps this most interesting forage plant will grow more successfully than it does here.

"You are wise indeed to protest in your journal against the destruction of forests. If the American people, so ready to destroy their trees, could only see the consequences of forest destruction in southern Europe and in northern Africa—the ground scorched by the sun in summer, overflowed and swept away by torrents in winter, the excessive droughts which destroy all crops, the drying up of streams, the vast and expensive public works necessary to provide means for artificial irrigation, etc., etc., they would understand perhaps better than they do now why nations should preserve their forests, and especially those which cover mountains. Forests are needed in the valleys, too, to furnish lumber and firewood, without which a civilized people cannot exist."

The fact that the tops of Pine and Spruce trees cut in the Maine woods can be utilized in the manufacture of paper-pulp has more than local or mere industrial significance. The fires which do such immense injury in the Coniferous forests of this country can generally be traced to the tops and branches of trees, left by the lumbermen behind them in the woods. These by the middle of the following summer become perfectly dry and afford the very best material to start a great fire with, in case a careless hunter or tramp or berry-picker drops a lighted match or a spark from his pipe into it. In Europe there is a demand always for such minor products of the forest; and the material itself pays for the cost of gathering up every part of the tree which the lumberman cannot make use of, to say nothing of the increased safety this gives to the forest, and to the priceless surface coating of decaying vegetable mould which fires consume. No one in this country has wanted the tops and branches of trees, and lumbermen have preferred to take the chance of almost inevitable fire rather than pay the cost of having the woods cleaned up behind their operations. The upper part of the main trunk as well as all the branches and chips and all

unsound logs, the whole amounting generally to a third of the whole bulk of the tree, has been left in the woods to burn or rot; while in the case of Hemlock it is only within a comparatively recent time that any use of the tree except the bark has paid. In some districts in Maine now, however, the tops and large branches of the trees are gathered; and the wood, from which the knots and sapwood is first removed, is thoroughly steamed to extract all resinous matter, and then ground into dry pulp. If it is profitable in Maine to do this, it will doubtless prove profitable in other parts of the country; and one of the principal causes of forest fires may perhaps in time be eliminated in this way.

The Pines in July.

BEAUTIFUL flowering plants greet us at every step in our midsummer walks through the damp Pine-barrens. Conspicuous among the shrubs is the Sweet Pepperbush (*Clethra alnifolia*), now covered with lovely racemes of white, scented flowers, and with it the White Swamp Honeysuckle (*Azalea viscosa*) is exhaling and blending its fine odor. The flowers of the Swamp Honeysuckle are in large, showy clusters. Some plants bear pure white flowers, while others have pink or pale rose-colored blossoms. Wild Roses still bloom among the other shrubs, and the Button-bush (*Cephalanthus occidentalis*) is too pretty to be passed by without mention. Its round head of fragrant white flowers and its foliage are both attractive, and I never pass it without adding some of its sprays to my wild bouquet.

The ponds are more beautiful this month than last. Their edges are fringed with a tall growth of rushes, sedges and grasses, which sway in the wind, revealing the flowers that hide among them. Charming Orchids are here, more beautiful than many exotic rarities which cost a king's ransom. The Grass Pink (*Calopogon pulchellus*), with a scape of from six to twelve showy, rose-purple flowers, is in the height of its beauty, as is also its ever-present companion, *Pogonia Ophioglossoides*, with paler rose-colored, sweet scented flowers. And the White-fringed Orchis (*Habenaria blephariglottis*), with its many-flowered spike of pure white flowers and cut-fringed petals, is surpassingly lovely. The Yellow-fringed Orchis (*H. ciliaris*), with bright, yellow-orange flowers, is handsome, too, and each makes the other appear to the best advantage. And the smaller Yellow-fringed Orchis (*H. cristata*) must not be left unnoticed and overshadowed by its more pretentious relatives. It is not so abundant as the others, and must be sought for, which makes it all the more charming when found.

All of these Orchids, with many other native species, will grow and thrive finely in a tub sunk in the ground, where they might be fit companions to the Water Lilies lately described in an editorial in GARDEN AND FOREST. They will grow in any common garden soil, but where it is practicable it is better to fill the tank or tub with the soil from their native haunts, and also to cover the surface of the ground with sphagnum, to give it a natural bog appearance; and the sphagnum will act as a barometer, telling when to apply water.

One is surprised to find how many of these plants can be grown in a small space. We can have a constant succession of charming flowers from early spring until late autumn, with no care after they are once established but to add water in times of drought.

The Cardinal flower (*Lobelia cardinalis*) is just coming into bloom, and the Pickerel-weed (*Pontederia cordata*) holds up its spike of blue flowers in striking contrast with the gorgeous scarlet of the Lobelia. Everywhere under foot are masses of bright, orange-colored flowers of *Polygala lutea*. And the large, showy, pink-purple flowers of Meadow Beauty (*Rhexia Virginica*) mingle with it. A little in the background stands our superb Lily (*Lilium superbum*), which lifts its magnificent pyramid of nodding

flowers far above my head. Many of the flowers are beyond my reach, but I can look up into the bell, and see the dark purple spots on its lining of orange. No more stately Lily grows in all the world. A little beyond, on dry, sandy soil, is the Orange-red Lily (*L. Philadelphiaicum*), with erect, bell-shaped, reddish flowers, also spotted with purple, while an exuberance of the glowing Butterfly-weed (*Asclepias tuberosa*) fairly illuminates the landscape. This plant is well named, for myriads of butterflies are contending for its sweets.

The Wild Bean (*Apios tuberosa*) clambers everywhere, covered with dense racemes of fragrant, pea-shaped flowers, while just beneath it trail the yellow clusters of the Pencil flower (*Stylosanthes elator*). Here, too, are seen the great purple flowers of the Beach Pea (*Lathyrus maritimus*), and the dense clusters of yellowish-white and pink flowers of the Goat's Rue (*Tephrosia Virginica*), creeping modestly about decayed stumps.

The little Partridge-berry (*Mitchella repens*) carpets the ground, and its delicate and fragrant flowers of white and pink are strung along in pairs among the glossy little leaves. And here blooms the Spotted Wintergreen (*Chimaphila maculata*), one of the most beautiful of modest wood-plants, with nodding flowers of waxy pink, while near by, beneath a thick growth of Chestnut Oaks, are great clusters of its pallid relative, the parasitic Indian Pipe (*Monotropa uniflora*).

And now I detect the anise-scent from the crushed leaves of the sweet Golden-Rod before I see the flower, which has already opened. It is the advance guard of autumn, announcing the approach of that tidal-wave of blue and gold that will cover all the waste places as with a sea, and make them more glorious in the dying year than they were in all the time of spring promise and summer ripeness.

Vineland, N. J.

Mary Treat.

Foreign Correspondence.

London Letter.

Stropholirion Californicum of Torrey is the most remarkable among the many hardy bulbous plants at present in bloom in the Royal Gardens at Kew. It is singular in growth, unique so far as I know as a bulbous plant possessing a tall twining flower scape. The Kew plant has now several scapes fully five feet high, and perhaps six feet when untwisted, and each is surmounted by a dense umbel of delicate rose-pink flowers of a peculiar shape, the perianth segments being saccate. There are no leaves to the plant now, so that the naked scapes have a strange appearance, twisting from left to right round stout stakes. It is perfectly hardy at Kew in light soil and seems to get stronger every year. It is not known much in a general way, though it is quite a "commercial" plant, as some of the nurserymen here term showy plants. It is nearly allied to *Brodiaea* and *Brevoortia*.

Heuchera sanguinea is another western plant (introduced five or six years ago) that has proved itself a hardy herbaceous plant of the highest value. Many are of my opinion that it is the finest hardy plant brought to this country for many years, because it has so many good points, being hardy beyond a doubt, rapid and sturdy of growth, not fastidious as to soil or situation, neat in growth and bearing a prodigious crop of the loveliest flowers. They are borne in paniculate spikes about a foot high, are small and bell shaped, and droop on slender stalks in a most graceful way. The color is a deep crimson coral, totally unlike any other flower of a similar class, and a color, moreover, which everybody admires, and especially for cut sprays and for vases. The foliage, like the rest of the *Heucheras*, is evergreen, of rounded outline, with shallow lobes. It is a native of northern Mexico, and was introduced in commerce by Mr. T. S. Ware, of Tottenham. I have just seen a large specimen of

it in a border, carrying quite a sheaf of bloom. It blooms for several weeks, beginning about the middle of June.

Romneya Coulteri.—I have just seen this glorious Californian Poppywort in flower in Kew gardens. It may, for aught I know, be a common plant with you, but with us it is one of the rarest and choicest border flowers we have. One need not be an enthusiast to admire its great satiny blossoms of snowy whiteness and adorned in the middle with a tuft of stamens like a golden tassel. There is such delightful harmony, too, between the glaucous and much divided leafage and the blooms. It has the reputation of being a "miffy" plant—that is, it wants much attention and then often does not reward us by behaving well. The best specimen I have seen of it was in a lady's garden in Surrey. This was four feet high and a yard across, bore many stems and many flowers, and so enraptured was I that I sat by the plant an hour. It is assuredly worthy of the stir that is made about it, and who could begrudge time and labor to bring such a fine flower to perfection? It would be wrong to call it a hardy plant; it is not strictly so, and I put it in the same category as *Carpenteria*, *Calochortus* and many other lovely plants from California.

The Blue Poppy of the Himalayas (*Meconopsis Wallichii*) is now the pride of many a hardy-flower lover. It has just commenced to unfold its stately pyramid of buds and will continue to bloom for several weeks to come. Among hardy plants this Poppy is unique in the color of its flowers, and no plant resembles its habit of growth. It is generally described as a perennial, but really it is but biennial in duration, as it develops its growth—a tuft of deeply pinnatifid leaves—the first season from seed, flowers the next, and then dies. The leaves are a foot or more long, of a pale green and densely covered with tawny brown hairs. The flower stem rises from three feet to even seven feet in height, according to the strength of the plant; it is generally much branched, and is loaded with a multitude of blossoms and buds. The open flowers are bell-shaped, two inches across, and of a peculiar shade of pale blue. The buds begin to open from the top downwards, the contrary being usually the case in plants. It is a perfectly hardy plant, but requires a spot sheltered from cold winds. The pale blue is the original color of the flower, but there is a variety with deep brownish-purple flowers named var. *fusco-purpurea*, and of this Mr. G. F. Wilson, the celebrated Lily grower in Surrey, had some fine blooms the other day. Mr. Wilson showed me at the same time a stem of the Caucasian Lily (*Lilium Szovitsianum*) measuring fully seven feet high, with a dozen of its handsome, primrose yellow flowers. There was also a stem of *L. Hansonii*, six feet high, carrying eleven flowers. These are average examples of the growth which Mr. Wilson gets in his Lilies, which are the admiration of all who see them.

The Sweet Pepperbush (*Clethra alnifolia*) in pots.—I fancy I omitted to mention in my last letter the fine display made by Messrs. Veitch of this American shrub at the last meeting of the Royal Horticultural Society. A dozen or more compact little pot bushes, averaging about two feet high and as much through, and each carrying a large number of flower spikes, were shown. The elegance of the bushes, their feathery spikes of white flowers, deliciously scented, attracted attention, and though such an old shrub in English gardens, I will say common shrub, it was known by comparatively few. Few persons have seen it grown as a pot plant. If it could be forced into bloom early in the season it would be charming for the green-house, as is also the Fringe tree, *Chionanthus Virginica*, which Messrs. Veitch showed in flower in pots in March.

Very interesting is the new race of late-blooming Azaleas derived from the lovely *A. occidentalis* of California, which for many years was only to be found in choice collections here. The development of these hybrids is due to Mr. Anthony Waterer, at whose nurseries I lately saw these beautiful and promising plants in bloom. The typical *A.*

occidentalis does not differ widely from other American Azaleas, such as *A. calendulacea* or *A. nudiflora*. It is deciduous, with bright green, shining foliage, and grows here from four to six feet high. The flowers are either pure white or stained with a ruddy tinge on their exteriors, while there is always a conspicuous yellow blotch on the upper petal. The fragrance is powerful and delicious. Usually the flower cluster is small and loose, and this is one of the defects Mr. Waterer has endeavored to remedy by intercrossing with his finest trussed Azaleas. The many new hybrids thus obtained have the characteristic features of *A. occidentalis*, with the large trusses and large and finely formed flowers of the fine early sorts. Moreover, some beautiful varieties have been obtained at Knap Hill by intercrossing *Azalea mollis* and *A. occidentalis*. At one time it was thought that such a cross would be impossible, but Mr. Waterer now has plants with the peculiar characters of both species, in foliage and growth as well as in flower. One variety, to be known in future as Mrs. F. L. Ames, has large trusses of snow-white flowers, with nothing to mar their purity save a delicate stain of yellow on the upper petal. The foliage is intermediate between that of the parents, while it loses nothing in fragrance. As the race is yet quite young, only the exceptionally fine sorts have been named and there are great expectations from the multitudes of unnamed seedlings. At the present time (July 7th) the Californian Azalea is flowering in perfection in Kew gardens, while all other sorts have been out of bloom for ten days or a fortnight. To prolong the Azalea flower season, which is unfortunately much too short, is one of the worthiest efforts of hybridists, who should be encouraged by such good results to proceed further.

A new Passion-flower, a fine hybrid, is now blooming in the Royal Gardens, Kew. It is a cross raised by Mr. Watson, the Assistant Curator, between the hardy *Passiflora carulea* and the Brazilian *P. Raddiana*. The flowers are larger than those of *P. Raddiana*, the petals and fringe longer, while the color is carmine, suffused with blue, which, though perhaps not so bright and pleasing as it is in the parent, is a lovely color. The growth is very graceful, the long shoots hanging down four or five feet like a curtain, and each thickly wreathed with flowers. It is likely to prove much hardier than *P. Raddiana*, which requires a stove, and as we have so few green-house Passion-flowers this novelty is a great addition. It is proposed to call it *Passiflora Kewensis*, so as to hereafter fix its birthplace.

Very beautiful is the new Californian shrub, *Carpenteria Californica*, against one of the old walls at Kew. It is one of the loveliest of all open-air shrubs, as no other bears such large, snowy flowers. The saucer-shaped flowers are quite three inches across, and the tuft of lemon-yellow stamens serves to emphasize the purity of petals. As many as a dozen buds and open flowers are on some of the branches. They are borne quite at the tip, and in moonshine shine like satin. It is a pity that this shrub is not hardy enough for culture as a bush in England generally, though in the Isle of Wight and the Devonshire coast it does not need the protection of a wall.

London, July 14th.

W. Goldring.

New or Little Known Plants.

Rhododendron brachycarpum.

THIS handsome and exceedingly hardy species of *Rhododendron* is a native of Japan, whence it was brought to this country with many other new plants by Mr. F. Gordon Dexter, of Boston, in the neighborhood of which city it has since found a place in Mr. Parkman's garden, without, however, having attracted the attention which its hardiness and the peculiar color of its flowers seem to justify.

*Rhododendron brachycarpum** is a tall, wide branching

* *R. brachycarpum*, G. Don, *Gen. Syst.*, iii. 843.—DC. *Prod.*, vii. 2, 723.—Gray, *Men. Acad. Arts and Sci.*, vi. 400.—Maximowicz, *Rhododendra Asiae Orientalis*, 22.—Franchet and Savatier, *Enum. Pl. Jap.*, i. 288.

shrub, which, in its native country, sometimes attains the height of ten feet. It has the habit and general appearance of the North American *R. Catawbiense*; the leaves, however, are terminated with a stout, short mucro, and are covered on the under surface with a fine, silky, rufous tomentum, while the flowers are pale yellow or cream color, the upper lobes of the corolla handsomely spotted with green on their inner surface. It is widely distributed in the mountain regions of northern and central Japan, covering vast tracts on Mt. Fudsi-yama above the limits of tree-growth, just as *R. Catawbiense* covers the upper treeless slopes of Roan Mountain in North Carolina.

Rhododendron brachycarpum is hardier in this climate than the Carolina plant or than many of the hybrids derived from that species, especially those with light colored flowers; its foliage is not burned or injured during the most severe winters even, and its flower-buds never suffer. These facts suggest the possibility of creating a new race of garden *Rhododendrons* with light colored flowers and hardier foliage than any we now possess, by mingling the blood of this Japanese species with that of some of the *Catawbiense* varieties. Cultural Department.

The Fruit Garden.

GOOSEBERRIES of foreign origin do not thrive in this country generally, and of native varieties, the Cluster or American Seedling and Houghton (Red), the difference between them being very slight, were almost absolutely successful till the introduction of the Downing, Mountain, and Smith's Improved. These being much larger than the preceding kinds and quite as free from mildew, rapidly superseded them and have held the field undisputed for ten years at least.

In point of merit they stand in the order named. The latter has never amounted to much here. The Mountain (Red) is the most vigorous grower, less productive than the Downing and a trifle smaller, but the Downing has been the leading Gooseberry in every respect for us. It now has a formidable rival in the Triumph, a berry a third larger, as vigorous and productive apparently, and of a greener color. As we use Gooseberries for canning or marketing in a mature, but yet unripe, condition, these qualities answer every purpose. Those who have become disgusted with attempting to grow the foreign kinds on account of their mildewing propensities need not hesitate to plant any of these American kinds through the dread of this pest. The new Industry Gooseberry, so highly commended, has proved a total failure with us. The plants could be persuaded to live a year or two and make a feeble attempt to grow, but they finally gave up the struggle without yielding a single specimen of fruit. This was one more proof that the plants of native origin are the only ones to trust. As a dessert fruit when ripe the Gooseberry is little used, but so long as pie holds its place as an article of diet, canned Gooseberries will always be in demand.

Of Blackberries, besides the old reliable Kittatinny we have the more recently introduced Early Cluster and the Erie. Between these two in point of earliness there is little to choose. Erie is the larger, but like the Lawton, it needs half its weight in sugar to be palatable. The Cluster is not so intensely sour, but most Blackberries have this defect unless they are thoroughly ripe, and it is impracticable to leave them on the canes till this stage is reached, because then the bees and wasps begin at once to prey upon them. These raiders are good judges of quality; they never attack a Blackberry until it is fully ripe. The Snyder is hardy and very productive, its small size being the chief objection to it. There is little choice between Snyder, Taylor and early Harvest. After all, the Kittatinny is the best one of the whole tribe we have ever seen or tasted. That it is so liable to the attack of the Orange rust is a great pity. A Vineland correspondent writes that he has the finest crop of Missouri Mammoth he ever saw of any variety, excelling even the Wilson, Jr.—a choice variety in that region. This Missouri Mammoth was tried here a score of years ago, but failed to show any striking merit. The old Dorchester, now very seldom met with or heard of, was one of the most satisfactory ever tried on our grounds. It was early, of fair size and good quality, not as rich as the Kittatinny, but it was never deceptive; if it appeared ripe it was ripe. It was only moderately productive as a rule, but in one exceptional season it

yielded an enormous crop. It certainly is worth a trial once more alongside of the newer varieties.

The Strawberry season was about ten days late in its arrival and departure. Chestnut trees are usually in full bloom July 4th, but this year did not reach that condition till the 16th, and yet the handsome and ever welcome little Doyenne d'Ete Pear was on time, giving us the first ripe specimens on the 20th of July as usual. How shall we account for such differences?

Montclair, N. J.

E. Williams.

Madame Ferdinand Jamain, but whether an old or a new variety, it has become decidedly popular, and apparently has come to stay.

An addition to this short list of summer Roses may possibly be made in the future by including the new Tea Rose Meteor. This brilliant colored variety, with its fair-sized flowers of bright crimson, has not proved a complete success for winter forcing, being apparently a shy bloomer at that season, but it appears to be of good constitution, and will most likely prove

Fig. 46.—*Rhododendron brachycarpum*.—See page 292.

A Few Summer Roses.

MARIE Guillot is probably the most satisfactory white Rose for summer use—its large, finely formed flowers, of good substance, keeping their character even in very warm weather. But though superior in hot weather, it is not equal to The Bride or Niphotos during the winter season. And the old favorite, Perle des Jardins, is decidedly the best of its color as a generally useful variety, though it has received some hard criticism during the past two or three seasons on account of its partial failure. But its bad behavior in many cases is probably due to the treatment it has received in former years, and there is little doubt but that it has lost some of its original vigor from hard forcing for several successive seasons. When young plants are propagated from this more or less exhausted growth, it is reasonable to suppose that they will lose a portion of their vitality. However, we have not yet found a variety capable of entirely superseding it (the Perle), and therefore it still remains a standard sort among the vast array of good Roses.

As a red variety, American Beauty, or as our European cousins persist in calling it, Madame Ferdinand Jamain, is one of the best, its fine, full flowers being alike useful to the amateur and to the trade-grower. As to the name of this variety, we have no special opinion to offer, though several clever rosarians have agreed that it is the Rose originally sent out as

valuable as a summer variety. An opinion has been expressed by an experienced cultivator that this rose should more properly be classed as a Hybrid Tea, and from its habit and appearance there seems to be good foundation for this opinion, but since it was introduced here as a pure Tea Rose, it has been so termed by the writer.

A few general remarks in regard to treatment may not be inappropriate.

In the first place free ventilation is essential, but when the nights are chilly, as frequently happens in the latter part of the summer, a corresponding reduction should be made in the ventilation, and in bright and dry weather frequent and thorough syringings should be given—twice a day is not too often.

A watering with liquid manure about once in two weeks will also be found beneficial, and in very hot weather a slight shading with very thin whitewash, or some similar preparation, will improve the quality of the flowers.

Of course a prompt application of sulphur will be made when mildew appears.

"H."

Christmas Roses at Christmas are yet a novelty in America. The problem of raising them here in sufficient quantity and cheaply enough for forcing has not yet been solved. Perhaps this can never be done in the open air in the Northern States. For trade purposes, it is necessary to import from Holland

and Germany, where they are raised in large quantities easily and cheaply. A mistake often made is importing too late in the season. They should not be shipped later than the 1st of November, or the flower stems push in transit, which is most undesirable. On arrival, the crowns, with leaves yet on, should be boxed and stored in frames and slightly shaded until the 1st of December, when they may be taken indoors and kept under benches free from drip until the flowering stems appear, when they may be exposed to full sunlight. A night temperature of over thirty-two degrees, Fahrenheit, is sufficient, with plenty of air during day-time. Thus treated the flowers will come clean, and with that natural and charming pink tinge which is so desirable.

Christmas Roses may also be planted in frames slightly covered with leaves, and kept from freezing by an abundance of outside packing, in addition to mats and shutters. But in this way there is difficulty in giving light and ventilation. Sometimes light and air cannot be admitted for days together. And the flowers do not come so fine, so abundantly, nor in such good condition, being often spotted. A pit with a false bottom and having a single pipe beneath would, I think, answer the purpose for forcing well. Treated as ordinary hardy subjects, having only the protection of a few leaves, Christmas Roses never bloom until spring here, and then very poorly.

Lychnis.—This genus is widely distributed throughout the northern hemisphere, and includes some of the oldest cultivated plants; all are of easy culture. *Lychnis alpina* is a dwarf, neat and pretty plant for the rock-garden, forming cushions about six inches high, surmounted by corymbs of rosy flowers. Although naturally perennial, it is little better than an annual here, usually dying after having ripened its seeds. Seedlings, self-sown, flower the following year. *L. Chalcedonica* is a fine border plant. It will hold its own almost anywhere. Seedlings bloom well the first year, and during the course of two or three years form large clumps. This is one of the few scarlet-flowering, hardy plants, and on that account is an attractive and prominent object wherever planted, when in bloom. *L. coronaria* is a very free, pretty, pink-flowered, border biennial. It is rather straggling in habit, but has handsome, grayish-white foliage, and remains in bloom a long time. It sows itself freely. *L. diurna* (Bachelor's Button) is a common plant, growing wild in Europe everywhere. The double form only is worth cultivating. It is propagated by division. *L. Flos-cuculi* (Cuckoo Flower, Ragged Robin) is a well known plant, growing wild in moist meadows throughout the northern hemisphere of the old world. The double form is an excellent border plant. *L. fulgens*, v. *Haageana*, is a very handsome plant for either border, rock-garden or for bedding. The flowers are wheel-shaped, often two inches across, in color varying from scarlet to white and purple. If the seed-pods or capsules are kept picked off it will bloom all summer. Seeds sown now, or later, and the plants taken into the green-house in fall, and kept pinched for a while, will make bushy plants and bloom well during the winter. *L. vespertina* is a common wild plant in Europe and Asia. The double form only is worth growing, and a very desirable plant it is. This variety does not admit of division, forming but a single root-stock, and must be propagated by cuttings, a slow and tedious process in this case, as the pipings are hollow. It is only young shoots, taken from the main stem in spring, which will grow. This plant is a continuous bloomer. It is in flower now, and will remain until frost, and if taken up carefully and housed would bloom most of the winter. The double flowers are the purest white and night scented. They are largely used for bouquet work in England. It grows eighteen inches high.

T. D. Hatfield.

Ripen the Wood.—Professor Johnson, in "How Crops Grow," lays down the fundamental principle that "the amount of food assimilated is not related to any special times or periods of development, but depends upon the stores of food accessible to the plant, and the favorableness of the weather to growth." The farmer, and more particularly the tree planter, can control the conditions favorable to growth in large measure, and he should so manage his cultivation of trees as to encourage early growth, leaving a long season for the maturing of the year's wood. Throughout the west, as a rule, the early spring is marked by frequent rains, followed in early summer by comparatively dry weather. Constant cultivation, however, will keep the soil moist and in fine condition for growth during the month of June and well into July. The habit of measuring cultivation by the number of plowings given is a bad one. Cultivation is only thorough when it

keeps the soil immediately below the surface moist, whether two or a dozen plowings are necessary.

During this season of rapid development the tree is assimilating more food than is needed for immediate use. After culture has ceased, a portion of the extra food thus prepared will be used in maturing the delicate shoots—the cell walls of such parts will be thickened and strengthened, or, in common parlance, the wood will become well ripened. The greater part of the surplus food will be stored in the young growth, ready for the use of the buds when they begin to develop in spring.

It is a prime necessity that the tree's store-houses be secure—that the new wood be well ripened. Late cultivation prolongs the period of growth, and hence retards the maturation of the shoots produced. If growth be too much prolonged the tree has no opportunity to mature the young wood, and winter killing is the result. Throughout the north-west cultivation of orchards and young forest plantations should cease by the middle of July, or the first of August at the latest.

Dakota Agricultural College, Brookings, July 25th.

Chas. A. Keffer.

Orchids in Bloom.—*Angracum Scottianum* is a comparatively new species, differing from the other members of the genus in possessing narrow, terete leaves and stem. The slender peduncles spring from the axils of the leaves, and bear two to three pure white flowers. The spur is yellowish and four to five inches long. This plant does well with us in the Phalanx-house in a basket of moss, being liberally supplied with water all the year. It is very free flowering, and lasts a long time in perfection.

Cypripedium Stonci is a superb and very distinct species, and was until recently somewhat scarce, but is now quite plentiful, and many fine specimens may be seen. The flower scapes are often two to three feet long, and bear three to four very handsome flowers. It not only should be in every collection, but would be found very useful to the florist for cut flower purposes. There are two or three good forms of this species, but the choicest is the very rare variety, *platytanium*. This we have never yet succeeded in bringing to bloom, but we find the plants grow best in a compost consisting of equal parts of loam, peat and moss, and being native of the warmest parts of Borneo, they should have strong heat, with plenty of water, and should not be overshaded.

Oncidium Papilio majus.—This variety is a vast improvement on the type both in color and in size of flower. The narrow upper segments on some now in bloom are fully four and a half inches long. The yellow lip is two and a half inches wide, with a very broad, orange-red band. It is a native of Trinidad, and grows equally well with us in both the cool and warm house on blocks of wood. The old flower spikes will continue to produce flowers for many years.

Kenwood, N. Y.

F. Goldring.

Surface Tillage.—At no season of the year is cultivation between the rows of growing crops more important than during the driest and hottest of summer weather. The chief reason for stirring the surface now is that this operation preserves the supply of soil-water for use by the rapidly growing crops. Incidentally the weeds are killed, and one great injury inflicted by weeds themselves is robbing the crops of the water they need. Deep cultivation is harmful now, not only because the ground is full of roots which would be mangled by the plow, but because it throws up the moist soil from below, and exposes it to the influence of sun and drying winds. But many experiments have proved that a shallow stirring of the surface tends to prevent evaporation from the soil. Evaporation takes place at the surface, and it goes on more rapidly in compact ground, because, as is supposed, of the continuous capillary connection between the surface and the deep soil-water, which is constantly rising. A shallow hoeing of the surface breaks the continuity of this capillary system and covers the open mouths of the tubes with loose earth, which acts as a mulch and prevents the escape of the water into the air. Whether this generally accepted theory is true or not, it is certain that the experience of every farmer and gardener has proved that surface tillage is a great help to crops in time of drought. In our climate crops could utilize much more water than the average supply during the growing season, and it is of prime importance to see that all waste is prevented. S.

Celery of any kind, whether self-blanching or not, is much more crisp and tender if banked with earth. A good way of preventing the earth from sifting in among the stalks, is to wrap each plant in a strip of butcher's paper, say from eight

to ten inches wide. With a garden trowel earth enough to hold the papers in place can be easily managed; then the plants should be hilled up almost to the top of the papers. This plan is recommended for early Celery and is not much more extra work than the tying up practiced by gardeners. Care must be taken to hold the plants erect while putting on the papers.

Plant Notes.

A Manchurian Bird Cherry.

OUR illustration represents a flowering branch of a form of *Prunus Padus*, doubtless of Manchurian origin, as it was raised from seed sent many years ago to the Arnold Arboretum from the St. Petersburg garden as *Prunus Maackii*, a Manchurian Bird Cherry, with pubes-

cent foliage and young branches, while those of this plant are quite glabrous and show no trace of the glandular dots which cover the under surface of the leaves of that species. In Mrs. Treat's notes (GARDEN AND FOREST, No. 21) on June flowers in the Pine regions of southern New Jersey, mention is made of our pretty Lake-flower (*Limnan-*

The European Lake-Flower.

any of the European Bird Cherries. No plant of its class in the collection equals this Manchurian tree in the size and beauty of its flowers. It grows with astonishing rapidity and is perfectly hardy; but, although plants here are now nearly twenty feet high and have flowered regularly for several years, they produce no fruit. In regions where late spring frosts, which would prove fatal to the early shoots and leaves of this tree, do not occur, it will prove an important and interesting addition to the list of small, hardy, ornamental trees. C. S. S.

Fig. 47.—*Prunus Padus*.

cent foliage and young branches, while those of this plant are quite glabrous and show no trace of the glandular dots which cover the under surface of the leaves of that species.

The old world Bird Cherry is a small tree widely distributed through the forests of northern and central Europe; it is found in the Caucasus and in the mountains of Afghanistan, and extends through Siberia to Kamtschatka, Manchuria, Mongolia and to Japan. The variety here figured is remarkable in the fact that its leaves appear fully ten days earlier than those of any other tree in the Arboretum, a peculiarity which gives to it no little interest and some value as an ornamental tree, apart from its very marked beauty when in flower. The racemes of large white flowers, which are deliciously fragrant, appear here early in May, fully two weeks earlier than those of the earliest of the American Bird Cherries, *Prunus Virginiana*, and long before those of

themum lacunosum). This plant is extremely rare about here, I judge. I can find no record of its occurrence in the field notes of local botanists, and have heard of but two limited localities where it has been found growing; and now it is wanting in both of these. Probably it was never an abundant plant; but the European species (*L. nymphaeoides*) is pretty sure to become common enough in the near future, and possibly will crowd out some of our native aquatics. It is not a bad exchange if it replaces our American plant—that of foreign gold for native silver; as the *L. nymphaeoides* bloom is “of a golden yellow color, beautifully fringed, and stands erect like the Water Poppies (*Limnocharis*).” There is a washout in a corner of my pasture meadow, in which Nelumbiums, Water Lilies and other choice aquatics are now growing, and where the golden Lake-flower was represented by a single plant

that had kept within bounds, notwithstanding the prediction of Mr. Sturtevant, from whom I obtained it. "Had kept within bounds" is no longer true of it. Not long since a dog plunged into the pond and tore this one plant into a dozen bits, and now every one is as flourishing as a Green Bay tree, and several are blooming as though the disruptive process was a stimulant to flower production. Two of the fragments of the original plant are far out in the trackless marsh, hidden by a jungle of native plants, but these are no check to its progress; and the European Lake-flower is an established fact. If it will not prove mischievous, long may it flourish!

Near Trenton, New Jersey

Chas. C. Abbott.

Malformation of Cabbage Leaf.

THE specimen from which the accompanying drawing was made was grown on the farm of Mr. Thomas Hume, in Alexandria County, Virginia. It belongs to the

Fig. 48.—Malformed Cabbage Leaf.

Early York variety, and has been observed in several plants. Malformation of this character, although well known, is far from common. Masters, in his "Vegetable Teratology" (p. 313), says: "In cabbages and lettuces there not unfrequently occurs a production of leaf-like processes projecting from the primary blade at a right angle. Sometimes these are developed in a tubular form, so as to form a series of little hornlike tubes or shallow troughs, as in *Aristolochia Sipho*. At other times the nerves or ribs of the leaf project beyond the blade, and bear, at their extremities, structures similar to those just described." The exact significance of this curious growth is not well known, nor indeed is the means of its production. Masters inclines to regard it as a disproportionate growth of some portions as contrasted with others, whence is usually produced a depressed cavity.

National Museum, Washington, D. C.

F. H. Knowlton.

Notes from the Arnold Arboretum.

THE three American species of *Hydrangea* are now in bloom. They are all useful garden shrubs, although the introduction of some of the more showy flowered Japanese species has no doubt caused gardeners to overlook them of late years. *Hydrangea arborescens* is the earliest to flower here by a few days, and, as an ornamental plant, is the least interesting and attractive. It is the most northern American representative of the genus, being found from northern New Jersey to Wisconsin, and southward through the Allegheny region. It is a vigorous shrub, sometimes six or seven feet high, with coarse, ovate, pointed and sharply serrate leaves, pubescent along the principal veins, as are also the young shoots, and rather small, flat cymes of yellow-white flowers, which in the most common form, are nearly always perfect. Varieties (var. *cordata*, *oblonga* and *sterilis*) are described by Torrey and Gray (*Fl. N. America*, i. 591) in which more or less of the flowers are sterile, with enlarged, petaloid

calyx-segments, but none of these, so far as I know, are in cultivation. They would be welcome additions to the Arboretum collection. *Hydrangea radiata* (the *H. nivea* of some collections) is a handsomer plant than the last. It is a native of the mountain country from South Carolina and Georgia to Tennessee, where it sometimes attains a height of six or eight feet. It has large, ovate, cordate, acuminate and sharply serrate leaves, dark green and velvety above, silvery white on the under surface, and fastigate cymes, in which the marginal or ray flowers are all sterile, very large and pure white. Individuals vary considerably in the degree of whiteness of the tomentum which covers the under surface of the leaves. This is a perfectly hardy plant of very considerable horticultural value. But far more showy and one of the finest of all *Hydrangeas* is *H. quercifolia*, a native of Georgia and northern Florida, where it is found in the middle country, occupying the rocky banks of streams, and growing sometimes, under favorable conditions, to a height of fifteen or eighteen feet, with almost tree-like habit. It has large and variously lobed or sinuate, minutely serrate leaves, sometimes twelve or fifteen inches long, tomentose when young, the upper surface finally quite glabrous. The flowers appear in large, crowded, thyrsoid panicles with spreading branches bearing here and there clusters of perfect flowers, and at the extremity a large sterile flower, which, when first expanded, is dull white, turning reddish before fading. The handsome foliage of this plant turns in the autumn to a deep, rich claret color. It is, unfortunately, not perfectly hardy in New England, and rarely attains anything like its full size here, although, if planted in partially shady situations, it will flower every year and soon spread over a considerable space. The only *Hydrangea* which resembles *H. quercifolia* in its paniced inflorescence is *H. paniculata*, the most common of the Japanese species in a wild state, and the only *Hydrangea* which ever becomes really arborescent. A variety of this plant (*H. paniculata grandiflora*), with enormous panicles, on which all the flowers are sterile, long a favorite among the Japanese, is now one of the most common shrubs in American gardens, where it blooms during the month of September. The form of this species in which the terminal flowers only, as in *H. quercifolia*, are neutral with enlarged calyx lobes, is, however, now in flower. In Japan it is a tree or tall shrub; here it makes a bush five or six feet high, with rather ridged branches covered with elliptical-ovate, sharply pointed leaves, sharply serrate only above the middle, roughly hispidulous on the upper and pubescent on the lower surface along the principal veins, as well as the petioles, young branches and panicles. Although far less showy than its better known variety, *Hydrangea paniculata* is a handsome and exceedingly free flowering plant, which has, moreover, the merit of blooming at a season of the year when flowers are not abundant. It was sent to the Arboretum by the Messrs. Parsons, of Flushing, and is still very rare in gardens.

Calluna vulgaris, the Heather of Europe, which is not rare, although very local, in Newfoundland, and was first discovered growing wild within the limits of the United States in the town of Tewksbury in this State by Mr. Jackson Dawson, is now in flower. It is a dwarf, compact, Heath-like shrub, one or two feet high, with short, obtuse, opposite leaves, densely crowded and imbricated on the wiry branches, and long, slender, terminal, spicate racemes of rose-colored flowers, with a colored calyx and bell-shaped corolla. There are varieties with white and with flesh-colored flowers, and one in which the flowers are double, as well as varieties with golden and with silver colored leaves. The *Calluna* is one of the very best of the dwarf hardy shrubs, it is an excellent rock-garden plant and it is useful to form low edgings. It is a good bee-plant, too, and it remains long in flower. In Europe it is largely planted to cover rocky and exposed hill-sides and to furnish shelter for game.

The most interesting shrub, however, in bloom this week, is *Stuartia pentagyna*, the only American representative of the Tea and Camellia family which can be grown in New England. It is a native of the mountains of North Carolina and Georgia. There is a second American species, *S. Virginica*, found in the coast regions from Virginia to Florida, but not hardy in the Northern States, and three Japanese species are described. Two of these are growing in the Arboretum, but they have not flowered yet. *S. pentagyna* is an erect shrub, ten or twelve feet high, with oval or ovate-acuminate, entire or mucronately serrate, deciduous leaves, and large, axillary, sub-sessile flowers, three or four inches across, with creamy white petals, deeply crenulated on the margins, and resembling those of some of the single Camellias. This plant, in spite of the fact that it has been cultivated for more than a

century, is rarely found in gardens, where, indeed, it is so rare that no common or English name seems to have come into use for it. The Carolina Stuartia is, nevertheless, one of the most attractive of hardy summer-blooming shrubs, and it should find a place in the smallest and most carefully selected collections. It is a plant of rather slow growth while young; and it needs to be fully established to develop all its beauties. It is found to thrive in a compost of peat and loam, enriched with an occasional dressing of well rotted manure.

Buddleia is the only member in the collection of the *Loganiaceæ*, a family of which the best known American representative is the so-called Yellow Jasmine of the Southern States (*Gelsemium*), and its only hardy representative among woody plants. There are two species here—*B. Lindleyana*, of China, and *B. curviflora*, of Japan. They are very similar, and as these species appear here they seem merely slightly marked varieties of the same plant. The stems suffer in severe winters, being sometimes killed quite down to the ground, but they always spring up again, and flower profusely at this season of the year. They are three or four feet high here, covered with large, ovate, sharply serrate, pointed leaves, and handsome, terminal, recurved racemes of purple-red flowers. But the interest in these plants is rather botanical than horticultural, and they will probably not be very often seen in American gardens, where many better plants are more at home.

And this is true of *Grewia parviflora* from northern China, a member of the family of which the Linden is the chief representative, and one of the plants for which the Arboretum is indebted to Dr. Brutschneider. Here it is a low shrub, two or three feet high, often killed to the ground in severe winters. The leaves are ample, with three prominent veins, unequally serrate, dark green and hispidulous above, pale and canescent on the lower surface. The small yellow flowers are borne in dense umbels, on stout erect peduncles opposite the leaves, which quite hide them from view. This interesting plant has no horticultural value.

Vitis (Cissus) indivisa is a handsome American species, now in flower. It is well suited for covering trellises or walls, although rarely met with in cultivation. *Vitis indivisa* is a vigorous growing plant, with stems fifteen or twenty feet long, climbing by means of tendrils. The leaves are four or five inches long, heart-shaped or truncate at the base, coarsely and sharply serrate, but not lobed. The panicle of flowers is small and loose, and the berries barely exceed a pea in size. It is a native of river banks from West Virginia and Ohio southward, and one of the hardiest and freest growing plants of its class.

Periploca Græca is a useful plant, too, for covering trellises, and for use in situations where a plant of very rapid growth is needed. It belongs to the Milk-weed family, and is a native of south-eastern Europe and the Orient, whence it was introduced into the gardens of western Europe fully three centuries ago. It has handsome bright green and shining ovate, or ovate-lanceolate, opposite leaves, five or six inches long, and small flowers, green without and purple on the inside, borne in loose, long peduncled corymbs. Twenty feet is not an excessive growth for this plant to make in a single season, but as it continues to grow late into the autumn, the wood does not always ripen, and the stems are then killed back, but only to start again the next spring with renewed vigor.

The development in late years of various garden races of *Clematis*, with very large and showy flowers, has had a tendency to cause many interesting and useful species of this plant to be neglected by gardeners. Three of these, however, now flowering with many others in the collection, are worthy of notice from a strictly horticultural point of view. They are *Clematis coccinea*, *C. graveolens* and *C. integrifolia*. *Clematis coccinea*, a native of Texas, is a smooth, slender vine, climbing to a height of six or eight feet, with three-foliolate, dark green, and rather coriaceous leaves, and solitary, nodding, bright scarlet, ovoid flowers an inch long, and borne on very long, erect terminal peduncles. The thick, coriaceous divisions of the perianth are strongly reflexed, with the interior surface clear, bright yellow. This plant, in spite of its extreme southern origin, is perfectly hardy here, and must be considered one of the best of recent introductions by all who see its abundant and showy flowers. *Clematis graveolens*, sometimes improperly called *C. Orientalis*, in gardens, a name which belongs to a Levantine plant, is a yellow flowered species from Chinese Tartary and the high passes of the western Himalayas. It is a smooth, graceful plant, climbing to a height of eight or ten feet, with slender, obtusely-angled branches, variously divided pinnate leaves, with petioled ovate or lanceolate leaflets, long, slender peduncles exceeding the leaves, and bearing a single clear yellow flower, an inch or more across.

The heads of fruit, with their long, feathery tails, are exceedingly ornamental, remaining upon the plant until winter. This is a perfectly hardy plant, thriving in any good garden soil, and one of the most desirable and attractive of the small flowered Clematisses. *Clematis integrifolia* is a native of eastern Europe and has been cultivated in gardens for nearly three centuries. This plant grows two or three feet high only, and the bright blue flowers are much smaller than those of the Hybrid Clematisses of the Jackman race, which flower with it, but they are as handsome, if not as conspicuous, and they are produced in equal profusion; while this plant is quite free from the diseases which, in this country, sooner or later carry away suddenly and unexpectedly all the hybrid Clematisses, and which make them so thoroughly unsatisfactory here.

July 29th.

The Forest.

The Forests of the United States.

IF the lumbermen of the United States will take the Ninth Volume of the 10th Census reports and read the estimates and statistics on the standing timber of the United States and compare with them the amount of timber cut and sold in the past eight years, in connection with careful estimates being now made over the same ground in the timber states of Michigan, Wisconsin, Minnesota, California, Oregon, Pennsylvania and Maine, they will be convinced that time has proved our estimates to have been approximately correct. The careful examination of that Census work, especially the object lessons presented by the maps of Forest areas, will give, too, some knowledge on timber matters. In Wisconsin, for example, the estimate in 1880 of standing Pine was some forty-one billion feet board measure, of which fifteen billion was in the Chippewa Valley. The eight years' cutting and the present amount of standing timber, estimated now at less than ten billion feet, show the 1880 estimate a fair one. Again the Redwood of California was estimated in the Census report at twenty-five billion; there has been an annual cutting of some three hundred and twenty-five million since; the present estimate being about twenty billion feet, and including much that is not very available. It is claimed that Michigan has less than thirty billion left, and the amount in Minnesota is probably about eight or ten billion feet. Since 1880, the available timber in the southern timber States, from the Carolinas around to and including Texas, the country of the Long-leaved Pine has been more thoroughly explored and estimated, and the available timber has been purchased largely, mostly by northern lumbermen who know the value of timber, and who, having sawed up or sold out their own, have bought this cheap pine and cypress as an investment, paying about twenty and twenty-five cents per thousand. These estimates and more careful reports of expert woodsmen do not add to the Census figures. I think, on the whole, the last report is generally the smaller. On the Pacific Coast, great changes have taken place in this respect. In California, up to 1880, little, if anything, was known of the amount or value of the Redwood of the coast or of the sugar pine of the Sierras. Now the former is all in hands of second and third parties, mostly owned by practical lumbermen who will hold and manufacture it. The sugar pine we may call a "reserve," as it can only be reached by long flumes. In Oregon there is not much change. In Washington Territory, especially about Puget Sound, there has been a decided advance in values, new mills have been built, large companies have been organized who are purchasing timber from the railroads and from Government and are preparing for extensive manufactures of the Fir and Cedar. To say that there is of the Firs, Cedars and other merchantable timbers in Washington Territory, Oregon and in the Pend d'Oreille Region of Idaho, five hundred billion feet, would I think, judging from an extensive examination made in 1882 and 1883, and from reliable sources, be low enough; that it will much exceed this estimate when cut, unless fires destroy it, is my belief. In the Middle States of West Virginia, Kentucky,

Tennessee, and in parts of Ohio, extensive bodies of the hard woods remain not much encroached upon. Still the steadily advancing prices, the greater demand all over the United States and from Europe for inside house-finish, agricultural implements, etc., show that these woods are getting more scarce and valuable.

North of us in Canada, lumber does not seem to cut the figure it once did. The inexhaustible forests of the distant regions have shrunk considerably under the more critical examination of timber buyers and their explorers. The Spanish River country, the North shore of Lake Superior, the vast "Limits" of the Lake of the Woods and the Rainy Lake river country, do not materialize in timber as represented by the Canada Company who sold the foreigners the "Limits." Winnipeg and the country westward is largely supplied now from the rivers in Minnesota that empty into Rainy Lake and the Lake of the Woods. The lumber is manufactured on the Canada Pacific Rail Road and sent over the road to Winnipeg and beyond. These are facts. I have no timber to sell, no reason to understate amounts, but I simply wish to make a fair statement based upon long study of the present condition of our forests which contain timber of commercial value.

Having referred in a former letter to European supply, I will add that the countries of Australia, China, Japan and Mexico already draw from us largely for lumber, their native supplies being mainly in almost inaccessible mountain regions. Mexico has considerable timber, but it is inaccessible at present, and it must probably remain so for a long time.

So we may congratulate ourselves here in the United States that we still have in our forests a wonderful inheritance, of a value that if estimated would run into the thousands of millions of dollars, and all this not covered up in the ground, but in plain sight and upon its surface.

Now, being forewarned by the experience of the old world, let us learn something. The Interior Department at Washington tells us, after more than ten years' trial of the Timber Culture Act on the prairies of Minnesota, Dakota, Kansas and Nebraska, that it is a miserable failure, though it agreed to convey for nothing one hundred and sixty acres of the best soil in the world to every man who could or would succeed in making ten acres of trees of any kind grow upon the land, after eight years' trial. They don't raise the trees. In after years it may be done, but so far the act is a failure, and should be repealed.

What we should learn is to preserve the forests we have by proper legislation, by educating and appointing foresters of intelligence to care for them, by publishing information on the subject—practical information, such as farmers and timber owners can readily understand and apply. American youths should be taught in school and at home that no fires must be allowed to run and that cattle must not run at large among young trees. District and graded schools should be supplied with collections of woods, and pupils should be encouraged to study them.

We appropriated millions upon millions of dollars' worth of land in 1862 for agricultural colleges. One million acres of this was taken in Wisconsin alone, and mostly for the benefit of other states. The Cornell University of New York took five hundred thousand acres of this Pine timber. Much of this land is to-day worth \$50 or more an acre for its timber. The same is true of Michigan and Minnesota. Henceforth the Government should in justice to these three states give to them outright the proceeds of future sales for the establishment of schools of forestry and to pay trained foresters to care for the forests. The same should be done in the southern timber states. An explorer in Alabama writes me, "I can buy for you in this state very finely-timbered Pine lands at Government price, \$1.25 per acre." Why not advance the price, if the Government must have the \$1.25 per acre, to \$2.50 per acre, and give Alabama the \$1.25 taken from the speculator, and let her have a school of forestry? All over our land we are losing millions by

ignorance and carelessness on the subject of forest fires. The people do not realize it at all, especially in our Western States and Territories. In Oregon, Washington Territory, Montana and Idaho, among the Firs and Yellow Pines, the fires are doing the most damage. I have seen millions of acres made bare by fires that were the result of carelessness along the railways in Washington Territory and Idaho. The very fact that a Government forester was ranging the forests about Puget Sound, the Columbia and Willamette Rivers would have a good influence in every lumber camp and along every railroad. I have seen one burning started by a gang of railroad workmen in Washington Territory that destroyed over one million dollars' worth of timber. This fire never would have occurred if such carelessness had been made criminal by law, and if an officer of the Government had been within reach to enforce it.

There is no question but that if \$250,000 a year even were properly spent in care of forests and forest education, it would add millions to future forest values.

Eau Claire, Wisconsin.

H. C. Putnam.

Correspondence.

To the Editor of GARDEN AND FOREST :

Sir.—About thirty years ago a gentleman imported many thousand trees from France and presented them to Dartmouth College.

They consisted of Norway Spruce, White Spruce, Scotch Pine, Austrian Pine, European Silver Fir, Larch, Linden, Ash, White Birch and Mountain Ash, English Oak, Norway Maple, Honey Locust and English Elm.

The Norway Spruces are as fine of their age as any I have seen in this country, and give promise of extending their upward growth eight or ten years longer. The European Larches are very fine and thrifty, and although they have not made as rapid growth as in northern Illinois and Wisconsin, on land of the same quality, yet in one essential point they are more promising than any others in the country, *i. e.*, they are perfecting their seeds, and young Larch trees are coming up freely around them. The European Larch trees producing seedlings stand on a cool, steep, northern slope, and from this I inferred that they possibly produced perfect seeds further north, and wrote to parties in Minnesota to whom we had furnished Larch trees many years ago, and learn that trees planted less than twenty years ago have seedlings springing up freely around them, some now over six feet high, while in Massachusetts, New York, Illinois, Iowa and Wisconsin they have never been known to produce perfect seeds. The specimen in the Bartram garden at Philadelphia, over 100 feet high and over 100 years old, was never known to produce a perfect seed.

Austrian and Scotch Pines are doing as well as I have seen them either east or west of here, but poorly when compared with White Pines in this vicinity. European Silver Fir is an entire failure. Even where well protected, it is not over four feet in height, killing back every winter. European Linden is hardy here.

A few English Oaks in well protected situations have made stems four or five inches in diameter. Where exposed they form a bush six or seven feet high. English Ash and English Elm kill back more or less in winter, according to exposure, and there are no good specimens. Norway Maple stands better than these, but does not endure the winter as well as at Milwaukee. European White Birch is quite at home. European Mountain Ash has apparently been planted quite freely, and many seedlings have sprung up where the original trees stood, but not a specimen now remains of the original planting.

The Honey Locust stands the winter, and makes a fine tree. White Spruce (*Picea alba*), of which there are a great number, were imported with the others. It has been much admired, and has been supposed to be a foreign tree. Every one is a fine specimen, and all are uniform in color, being very glaucous. I am inclined to think that they belong to a variety known as *Cœrulea*, which was propagated extensively in French nurseries thirty years ago. Certainly I never saw a hundred White Spruces so uniform in color before. They all give promise of making durable trees.

I have made an examination of the native as well as the imported trees here. I measured an American White Elm, planted in 1790, which is fourteen feet in circumference four feet from the ground. Sugar Maples of unknown age are over nine

feet in circumference. A White Oak in the cemetery measures more than twelve feet in circumference. A native Mountain Ash—fifty-eight inches in circumference three feet from the ground—a beautiful tree, stands in an old Pine-stump fence, in perfect health and loaded with fruit.

The White Pines and Hemlocks are magnificent hereabouts. Not a Red Pine tree to be found in this neighborhood, so that a comparison cannot be made between this Pine and the Scotch and Austrian Pines. Canoe Birches over six feet in circumference of trunk are not uncommon.

The Norway Spruces, Austrian and Scotch Pines no doubt added much to the beauty and interest of this plantation for many years, as they grow so much faster than our natives while young. If a similar plantation were to be made now, a judicious mixture of White and Red Pine and Hemlocks should be added to take the places of the Norway Spruces, Scotch and Austrian Pines, which could be thinned out as occasion requires.

Hanover, N. H.

Robert Douglass.

[Seedling European Larches, although not in large numbers, have appeared in the plantation of this tree made many years ago by the late Richard S. Fay, near Lynn, in Massachusetts. An account of this plantation, one of the largest and most successful ever made in the United States with exotic trees, will be found in the Report of the Massachusetts State Board of Agriculture for 1875.—ED.]

To the Editor of GARDEN AND FOREST:

Sir.—My lawn at the sea-shore extends from the house to the water's edge, and is exposed to the south-west winds. It has run to sorrel and weeds, and must be rejuvenated. Will you kindly tell me through your columns the best thing I can do with it, so as to have a fair turf by June 15th, next year, and not disturb it before the middle of September, this year. What is the best seed to sow and the best dressing to use? The soil is good.

Theoph. Parsons.

Mattapoisett, Mass.

[It is not an easy matter to make a good lawn within the time specified. The seed should be sown this autumn, and, if possible, it should be in the ground before the middle of September, or as soon after as possible. Break the ground up deeply. Cover with well-rotted manure at the rate of thirty to fifty tip cart loads to the acre. Harrow this in deeply with an Acme or spring-tooth harrow. Roll the ground and harrow again, repeating the operations until the soil is very finely pulverized and yet firmly compacted. Sow Kentucky Blue Grass and Rhode Island Bent at the rate of at least four bushels per acre. Then sow Timothy seed at the rate of a peck to the acre; rake all in lightly and roll again. Timothy is not a lawn grass, but the seed can be had pure and it germinates quickly. It will make a fair show before winter sets in, and next spring can be cut over several times before June 15th. This cutting will keep down the Timothy, and prevent its growing coarse and strong while the Blue Grass and Bent are becoming established. The last two will ultimately crowd out the Timothy, which is only needed for its early effect. Without it the grass would be unpleasantly thin next spring. It would be well to give the lawn a top dressing of fine manure after the ground freezes, to remain all winter as a mulch, and for its fertilizing effect.—ED.]

Recent Publications.

Trees and Tree Planting.—By General James S. Brisbin. New York: Harper & Brothers.

This work will meet a friendly reception from all who are interested in forestry as a national question. It is a vigorous protest against the reckless waste of the forests of the country, and an appeal for the exercise of intelligence and patriotic prudence in the treatment of trees. General Brisbin's love of trees—by which the book is inspired—has been life-long. Some of the most pleasant passages in the volume are those in which he recalls the impressions made upon him in boyhood by the mountain forests of Pennsylvania, his native state. It was not, however, until in the course of his professional travels he had seen the savage and inhospitable sterility of the plains, that he was awakened to the importance

of the part played by the forests in their relations to human life and industry. An incident which he relates in his introduction suggests vividly the exhilaration of mind produced by the first sight of living trees after long exile in the western waste. "For four years," he says, "I had lived on the plains, surrounded by sage-brush and sand, never once seeing a mountain or forest. Then I was ordered east with troops to Kentucky. We had been running very fast all night in the cars, and in the morning, just as I was washing in the sleeping-car, I heard the soldiers in the forward coaches cheering. I asked the conductor what was the matter, and he replied, 'The soldiers are cheering the trees.' We all hastened to the doors and windows, and there, sure enough, we found we were running through a grand old Kentucky forest. . . . Even the children clapped their little hands and cried out, 'Oh, mamma, see the pretty trees!'"

General Brisbin's book does not pretend to be an elaborate treatise on the scientific aspects of the subject; indeed, in a modest sentence he in effect disclaims for it at the outset any such character. This prepares one for a certain readiness on his part to adopt theories which are not considered tenable by the more cautious investigators. Nevertheless, the scope of the work is large, and it contains a great amount of valuable information, industriously collected from a number of sources, of varying authority. The opening chapters deal with topics of a general nature, such as "Forest Destruction and its Consequences," "Effect of Forests on a Country," "Danger of Timber Famine," "Shelter Belts," etc. A short chapter entitled "Famous Trees of the World," is full of entertaining information. The greater part of the volume is devoted to a description of well-known trees, both native and foreign.

It is significant of the growing interest in forest production and preservation that one who is presumably without technical training in the art of forestry or in the sciences upon which the best forest practice is based should have been led to pursue this line of inquiry. The perusal of this book cannot fail to arouse and stimulate concern regarding one of the most urgent problems that confront us as a nation at the present day.

Messrs. Hyde & Co. of this city have just published an excellent "Road Chart" for the suburbs of New York. It covers not only Manhattan Island, but Staten Island, Kings and Queens Counties in Long Island, the mainland of New York State for a long distance north of the city and beyond Tuxedo to the west, portions of Fairfield County in Connecticut, and the New Jersey country further west than Morristown and further south than New Brunswick; and it distinguishes between good and poor driving roads, indicates those which are fit only for foot-travel, marks the character of the land as low, marshy, etc., and names the owners of the chief country-places included in its wide circuit. Such a map should open up the beautiful districts around New York to hundreds of urban and suburban residents who have hitherto been discouraged from personal investigation by the difficulty of ascertaining just where and how to go and just what attractions await them by the way.

Recent Plant Portraits.

Botanical Magazine, July.

MACROTOMIA BENTHAMII, *t.* 7003; a stout, hairy herb, of the Borage Family, with dark, maroon-purple flowers, in a large, terminal thyrsus; a native of the western Himalaya and of Cashmere, where it is common at great elevations.

ASPHODELUS ACAULIS, *t.* 7004; a pink-flowered Asphodel, from Oran and Algiers, with pink flowers arranged in a lax corymb, the peduncle nearly obsolete, and the general habit of the plant like that of *Ornithogalum umbellatum*.

ILLICIAM VERUM, *t.* 7005; "The plant producing the true Star Anise of China is here for the first time figured and described. For many years the fruit so called was supposed to be that of *Illicium anisatum*, the *Skimmi* of Japan, or of *I. religiosum*, supposed to be a native of China, but which is identical with *I. anisatum* of Linnæus and Loureiro. . . . The first person to recognize the fact that neither *I. anisatum* of Linnæus or of Loureiro could be the true Star Anise of China was Dr. Bretschneider, who called attention to the fact that the Japanese plant was a reputed poison and that this had been confirmed by Eykman, who, in a paper published in 1881 in the *Mittheilung der Deutsche Gesellschaft für Natur- und Volkenkunde Osten Asien* (Heft, xxiii. 23), had experimented with and given the name of Sikimine to the poison. . . . In his 'Notes on Botanical Questions Connected with the Export Trade of China,' printed at Peking in 1880, Dr. Bretschneider calls attention to a Report by Mr. Piry on the trade

of Pakhoi for 1878-9, which contains interesting particulars regarding the Star Anise. Of this he says it is brought to this port for exportation from the province of Kuangsi via Kin-Chow, and that it is produced in two districts—Lung-Chow, on the borders of Annam, and Po-se, in the West (or Canton) River, close to Yun-nan.

"The Star Anise was, according to Hanbury (*Pharmacographia*, Ed. 2, p. 22), first brought to Europe by the voyager Candish about the year 1588, and was first described by Clusius in 1601 from fruits procured from Loudon. It seems afterwards to have been imported via Russia (and hence called *Cardamomum Siberiense*, or *Annis de Siberie*), and was used by the Dutch in the seventeenth century to flavor beverages. From China it is exported into eastern Turkestan under the name of Chinese Fennel, and in China itself it is called *Pakio nui hiang*, or eight-horned Fennel; the fact being that though commonly compared with Aniseed, the taste is really more like that of Fennel, so that the name given by Redi in 1675 was *Faniculum sinense*.

"In China the Star Anise is employed as a condiment and as a spice, and it is still used to flavor spirits in Germany, France (where it is the flavoring material of *Anisette de Bordeaux*) and Italy. In England, according to Hanbury, it is used only as a substitute for oil of anise." *I. verum* has small, globose flowers, without the long, spreading, inner, perianth-segments of *I. anisatum* or *religiosum*, or of our southern *I. Floridanum*, belonging to an entirely different section of the genus.

CELOGYNE GRAMMINIGOLIA, *t.* 7006; a graceful species, with short basal scapes, bearing two or four white flowers, with a three-lobed lip streaked with purple; a native of Moulemein and the representative of a section of the genus widely distributed through the mountain region of India.

CYPERORCHIS ELEGANS, *t.* 7007; this is the *Cymbidium elegans* of Lindley, a Himalayan species, with handsome yellow flowers an inch and a half long, arranged in a long, dense, pendulous raceme. There are two species of *Cyperorchis*, this, and the fragrant, white-flowered *C. Mastersii*.—*Botanical Register*, 1845, *t.* 50.

Notes.

Sixteen bushels of nuts were gathered last year from two English Walnut trees planted thirty years ago in Contra Costa County, California.

The fine specimen of the California White Oak (*Quercus lobata*) upon General Bidwell's farm, known as the "Sir Joseph Hooker Oak," to which reference was made on page 275 of GARDEN AND FOREST, has a trunk diameter of seven feet and three inches, while the branches spread one hundred and forty feet.

American inventors are invited to send for competition to the Exhibition of the Imperial Society of Austrian Pomologists apparatus to be used in the cultivation of fruits, and in their subsequent disposition by pressing for beverages, drying, packing and other methods of preservation. The exhibition will be held at Vienna from September 29th to October 7th.

An interesting sight on the grounds of Mr. Peter Henderson, Jersey City Heights, is a field of Lima Beans, which are also strictly Bush Beans. The plants are erect, from fifteen to eighteen inches high, and bear up sturdily under a heavy load of short, though well-filled, pods. The beans are apparently identical with the small variety of the Lima known as the Sieva.

Insect Life is the title of a new periodical bulletin devoted to the economy and life-habits of insects, especially in their relation to agriculture. It is published at Washington, and edited by the entomologist of the Department of Agriculture and his assistants. Professor Riley announces that it will be issued as regularly as an ordinary monthly, and will complete the first volume with the year.

Throughout a considerable district in northern New Jersey the potato-tops have been dying before they reach maturity, and many fields of late varieties will not yield half a crop. Mr. Carman, of the *Rural New Yorker*, has found that the destruction is caused by the Cucumber flea beetle, an enemy easily overlooked on account of its small size, and one, too, not suspected of being capable of causing so great damage.

Professor Riley reports the imported Asparagus Beetle (*Crioceris asparagi*) as gradually spreading southward. Following the coast and the water-courses, it was found four years ago at Cherrystone Creek, Maryland, and in 1886 it had reached Old Point Comfort. Inland it spreads more slowly and never damaged Asparagus beds in Washington until 1887. The

most southern inland point where it has been reported is Falls Church, Fairfax County, Virginia.

The Paulownia has so long been familiar in our Middle States as a tree of large size, that it seems curious to read in a German periodical an enthusiastic article describing, as a noteworthy object, a tree of this species which has attained a height of five and a half metres. We are told that it blooms each season, but that year by year it develops smaller leaves and has probably passed its prime. The first Paulownia which bloomed in Europe was one in Paris the flowers of which appeared in 1842.

A page in a recent number of the *Illustrirte Garten Zeitung* of Vienna is devoted to praise of the Niagara Grape and descriptions of the success which has attended its cultivation in this country. Three years ago, the author states, specimens of its fruit were exhibited at a Congress of the Fruit Growers of Lower Austria and a local grower was induced to attempt its production by the same cross from which it had resulted in America. His young vines already look so well, it is added, that their fruiting is awaited with extreme interest.

About thirty miles in a south-westerly direction from Paris, in the old town of Rambouillet, is a so-called English garden, which dates from about the year 1780. Here is a grove of fully one hundred of our Southern deciduous Cypresses (*Taxodium distichum*), which are probably the finest to be seen in Europe. They are growing in a low, moist piece of ground, perhaps six acres in extent, and well suited to their development. In the spring their bright green colors and graceful forms make a strikingly beautiful picture. In the "French Garden," on the other side of the famous chateau, is an avenue of the same kind of tree, about 400 yards long, in which many of the trees measure four feet in diameter.

There have been in Germany during the last twelve years sixteen scientific stations devoted to the investigation of meteorological and other phenomena connected with the forest. At the Eberswald Station observations have been taken during a number of years for the purpose of determining the difference in the temperature of the soil in the forest and in the open ground. Two posts were established, the first in a grove of Scotch Pines forty-five years old, and 375 feet from the open ground, the other at a point 795 feet from any wood. At each of these stations readings of the thermometer have been taken daily at 8 A. M. and at 2 P. M. at the surface, and at depths varying from six inches to four feet below the surface. The results of these observations may be briefly stated to be: that the temperature of the soil at the different depths averages one degree higher in the forest during the winter than in the open ground, and that it is nearly three degrees cooler in summer, so that the extreme variations of the soil are four degrees less in the woods than in the open ground; that the forest has the same effect upon temperature as depth below the surface has—that is, it retards and modifies extremes, and makes variations slower and more regular in their appearance and disappearance. A full account of these experiments and others carried on at these stations can be found in the annual reports which Dr. Mutrich has published since 1875, and which can be obtained from the Berlin bookseller Springer, 3 Monbijonplatz.

The feature of the Saturday exhibition of the Massachusetts Horticultural Society on August 4th consisted of several large collections of Sweet Peas. The finest flowers in twelve unnamed varieties were shown by Mr. W. Patterson, gardener to Mrs. Charles Francis Adams, of Quincy. M. B. Faxon, the Boston seedsman, staged twenty-five named varieties, of which the finest were Black Purple, with dark, rich, purple, nearly black flowers of fine substance and color; Butterfly, light, clear lilac; Painted Lady, pink and white, clear and very delicate; and Invincible, dark, clear scarlet, and by far the handsomest flower in the collection. Many of the newer varieties are lacking in clearness of color, and give evidence that too much attention has been given to the development of large flowers at the expense of clear self-colors. Sweet Peas are now great favorites with the public, and the windows of Boston florists often contain beautiful displays of this flower, tastefully arranged with Maidenhair Ferns, Summer Carnations and trailing Asparagus. At the same meeting of the Massachusetts Horticultural Society Mr. James Comley, gardener to Mrs. F. B. Hayes, of Lexington, exhibited the flowers of a number of interesting hybrids between *Nymphæa cyanea* and *N. dentata*, showing a considerable variety of form and several distinct shades of color, from pale to very dark blue. These are the first flowers from several thousand hybrids raised by Mr. Comley, and seem full of promise for the development and improvement of Water Lilies.

The Society of American Florists.

THIS association, although young in years, has already become, in the broadest sense of the word, a national organization, embracing in its membership the most prominent commercial growers of plants and flowers in every state of the Union. Subordinate societies, known as Florists' Clubs, have been formed in many cities, and the frequent meeting of these clubs and their vital connection with the parent society make an organization strong and efficient to secure with certainty and promptness every advantage that comes from co-operative effort. Primarily, it is a trade organization, created and developed for the benefit of that rapidly increasing class who have a business interest in growing plants and cut flowers. In a genuine sense, however, the influence of the society reaches all who love flowers and cultivate them, and this influence, so far as we know, has been for good only. In some cases, it is true, the formation of a Florists' Club has been followed by the sudden death of the local Horticultural Society, but societies with such feeble vitality have little excuse for surviving. There is no essential conflict between the trade-associations, whose work lies in one special direction, and the horticultural societies, which occupy a broader field for purposes other than commercial. The two associations should be mutually helpful, and all the more so when each is held strictly to its distinctive work. Certainly a horticultural society falls short of its highest aim when it is managed so exclusively in the interest of trade that the establishment of a florists' business club in its neighborhood leaves nothing for it to do.

Horticulture, in the fullness of its meaning, is a domain which this association and its offshoots do not attempt to occupy, and yet while working in their restricted field and for a special purpose, the meeting of the florists here in annual convention this week has awakened more general attention than any similar gathering in recent years. This is partly owing to the fact that the promised attendance will be much larger, that the subjects announced for discussion are of greater practical interest, and that the exhibition of plants, flowers and florists' appliances will be

more varied and extensive than at any former meeting. But behind all this is the additional fact that flowers and floriculture have a deeper hold upon the affections of the people every year, especially in New York, the centre of the most important Rose-growing district in the country, and the market in which more cut flowers are sold than in any other city on the globe. The cultural questions discussed will be an education to amateurs as well as to the members, and so will all information relating to the special habits and uses of different plants, to the use of insecticides, to the construction of green-houses, and to other matters of practice. In a wider sense every discovery made and every forward step taken, that will prove helpful to the members from a business point of view, will also be of advantage to the buyer, as it enables him to secure plants and flowers with less trouble and expense. The reduction of postage on plants, seeds and bulbs, for example, which has just been effected, largely through the labors of this organization, will make it possible for all who buy plants to secure larger ones and more of them at the old rates, not only through the mails, but by express as well, for express charges will be reduced as they come in competition with the post.

To the members themselves the value of these gatherings can hardly be overestimated. The production of flowers under artificial conditions, and at unnatural seasons, together with the weakening effect of high cultivation and the inbreeding of varieties, have inevitably developed diseases and pests hitherto unnoticed or unknown, and in the study of these difficulties a comparison of experience by men from widely separated regions is an invaluable aid. Nor will this interchange of experimental knowledge be confined to any single topic, but will be found of value throughout the entire range of commercial and cultural practice. And again, the instruction thus imparted will not be derived alone from the formal addresses and the still more suggestive discussions that follow them. One of the leading plantmen of the country recently stated that a suggestion dropped by a fellow member in a casual conversation at a meeting of the Association in Chicago had enabled him to save thousands of dollars in glazing his green-houses alone. Apart, then, from the recreative and social features of this meeting, from the instruction and pleasure offered by the exhibition, which will illustrate the most progressive practice in every department of floriculture and floral decoration, and the advantages that come from travel and enlarged acquaintance, the intimate association for days together of several hundred alert business men, engaged in the same pursuit and studying the same problems, must tend to give every member fresh ideas, quicken his spirit of enterprise and broaden his mental horizon.

The Society of American Florists has already accomplished enough to justify the hopes of its founders, to merit the good will and command the respect of all who are interested in floriculture. It is under the guidance of intelligent and progressive men, and it is destined to wield a still more important influence as the great industry which it represents continues its wonderful growth. It is only when we consider how largely the public is dependent upon nurserymen, seedsmen and florists for instruction in practical horticulture, and to what extent the buyer's selection of varieties is controlled by the illustrations in their catalogues, the trees, shrubs and vines in their trial grounds; the floral displays in their shop windows, and the discussions in their societies, that we begin to realize the public importance of these gatherings. Fortunately the tendency of these meetings, so far as they are educational, is towards greater simplicity and naturalness in the way of decorative planting and floral arrangement. A steady progress in this direction is manifested in the trade from year to year, and if the time should come when the leading members of the Society are not as conspicuous for good taste as for business enterprise and ability, it will not be the result of the deliberations at these assemblies.

Spring-Flowering Bulbs.

THIS is the season of the year when the catalogues of the Dutch bulb-growers should be carefully studied, and when people should determine what bulbs they will plant for the decoration of their gardens in spring and where and in what manner they shall be planted. The bulbs need not be placed in the ground until October or even until November, but it is well, in all that relates to the garden, to take time by the forelock, and not to put off the planning of planting operations until the planting time actually comes. And if the bulbs are imported direct from one of the great Dutch bulb-farms, as is the most satisfactory and economical method if many plants are needed, six weeks at least will pass after the order is sent before the bulbs arrive, so that if it is sent late in the present month or early in September, the plants will not arrive too early for autumn planting.

The cultivation of hardy spring-flowering bulbs is one of the most delightful, as it is one of the most satisfactory of all forms of gardening. Many of the plants classed under this head yield flowers which no inhabitant of the tropics can excel in delicate charm or in gorgeous splendor. No plants are more easily cultivated, and none give so much pleasure for the small amount of money which they cost. Many of them increase and multiply without care, beyond the first planting, and, once established, go on flowering year after year almost indefinitely.

There is a charm in these early spring flowers, appearing among the melting snows, the first indication that the long winter has come to an end, which each year grows stronger and stronger, and which no other feeling inspired by the contemplation of Nature's workings ever quite resembles. Men tire of the most splendid Orchids of the tropics, of the masses of color which modern horticulture spreads over the Chinese Azaleas, of all the garden show and gorgeousness of these later days, but who has ever tired of a Snow-drop or a Daffodil in early spring?

There is a much larger variety of hardy spring-flowering bulbous plants than are usually met with in American gardens, which, by a proper selection, may be made gay or interesting with them from March until July, or from the time when the earliest Snowdrops and Crocuses appear, until the blooming of the so-called Spanish and English Irises in mid-summer. Many new species and varieties of the Crocus have been introduced into gardens of late years, and the blooming period of the plants of this genus has, in this way, been materially prolonged. Among Squills there are many charming flowers blooming in succession during six or seven weeks. The number of different Narcissus which can now be grown is almost endless. The attention which has been bestowed upon these plants of late years in England, by botanists and by gardeners, is one of the most interesting phases of modern horticulture. It has resulted in the reintroduction of many species of Narcissus long lost to gardens, and in the production of many new hybrids of more than passing interest and value. The Tulip and the Hyacinth are too well known to need mention here; except to call attention to the fact that many of the species of Tulip, which have been described at different times in the columns of this Journal, exceed in beauty as they certainly do in interest, those of the more familiar garden races. They should find place in every garden, with quantities of Narcissus and Squills, Alliums and Snowdrops, Snowflakes and Crocuses, Fritillaries and Dogtooth Violets, Ornithogalums and Lilies-of-the-Valley. There never was a garden in which there were too many of these plants, or in which some corner could not have been found which might have been made more attractive by their presence.

Persons who have only seen spring flowering bulbs in formal garden beds can form but a faint idea of the pleasure which can be got from them when they are planted in natural groups or masses along the borders of wood-walks, in the fields among grass, or in the rough and unkept parts of the garden. Our illustration upon page

306, representing a quantity of the Poet's Narcissus, and of one of the late blooming tall Squills (*S. campanulata*), grown in this way near a wood-walk in a garden in Massachusetts will serve, perhaps, to give a slight idea of how such plants can be properly associated together, and how their greatest charm and beauty can be brought out.

All bulbous plants, however, cannot be satisfactorily used in this way. A garden Tulip or a garden Hyacinth planted in the grass appears as much out of place as a Dock in a trim parterre; but all the Narcissus look better in the grass than in a border, especially the Poet's Narcissus, and the Jonquil. Crocuses are more attractive when planted in this way than in formal beds or as edgings; although they harmonize less perfectly with their surroundings than Squills, all of which look their best when allowed to run wild. Many bulbs last longer and increase more rapidly when left to themselves in this way, than when planted in borders, from which it is often necessary to remove them. It is essential, however, that all these plants should be allowed to thoroughly mature and ripen their foliage. They cannot, therefore, be planted in grass, which is cut early in the season, and even if this were not the case, such plants springing from closely cut turf look less at home and less natural than when they grow among tall grasses or the wild plants which are found along the borders of woods or on rocky banks. These bulbous plants delight almost universally in deep, rich soil, and if they are to be naturalized, and are expected to flower year after year, and to increase, it should be provided for them when the bulbs are first planted. If this is done, no further care or attention need ever be paid to them; and every year when they bloom, the fortunate possessor of a garden in which such plants thrive, will rejoice with a new and ever increasing joy.

Mr. John Kenrick established in 1797 a commercial nursery of ornamental trees in Newton, Massachusetts. Two acres, a large piece of ground for such a purpose at that time, he devoted to the cultivation of the Lombardy Poplar, which was about the only ornamental tree for which there was any demand in those days. It is worthy of remark that the Poplars which Mr. Kenrick and others propagated and distributed by thousands and by tens of thousands early in this century have now nearly all disappeared. Here and there a decrepit and half dead Lombardy Poplar may still be seen in the Eastern States, but their beauty is a thing of the past, and each year reduces their number. It is not old age alone which affects them, for young trees, after growing during a few years with vigor and rapidity, perish by piecemeal, branch after branch falling away without any apparent cause; and it is not the climate of America which is fatal to this tree, for it is disappearing in Europe in the same manner. These trees abounded in France, in Germany and in Italy half a century ago; now they are comparatively rare in those countries, and the specimens which remain are not more healthy than those seen in the United States. It is not improbable, therefore, that the Lombardy Poplar will disappear entirely. All the individuals of this tree, which is considered an abnormal form of the Black European Poplar, have descended probably from one or from a comparatively few individuals whose peculiarities and weaknesses of constitution have thus been handed down from individual to individual without change, and without the infusion of new blood which plants derive from cross-fertilization among individuals of the same species, or by the hybridization of nearly allied species, and without which no race can endure for any considerable period. Cases are not unknown where plants propagated exclusively by division, for the purpose of perpetuating some peculiar characteristic not transmittable to their offspring in the natural way, have entirely disappeared; and this will probably prove true, sooner or later, of many trees of

abnormal habit like the Lombardy Poplar and of trees with peculiarly cut or variegated foliage, although there is always the chance that seedlings will appear with similar peculiarities to renew the race with fresh blood. The Purple Beech, for example, so potent is the peculiarity to which it owes its name, often comes true from seed; but individual peculiarities of this sort are not, as a rule, very firmly fixed in the case of trees, and cannot be depended upon to repeat themselves with much certainty. It is fortunate that they cannot, and that many of the monstrosities in which modern planters so delight are blessed with feeble constitutions, and are doomed to disappear entirely off the face of the earth. But the failure of the Lombardy Poplar is not a blessing. Planted as it was a hundred, or even fifty, years ago, in all possible situations, without regard to its surroundings or to the positions in which it was placed, it did more, perhaps, than any tree which has ever been planted, especially in some parts of Europe, to disfigure the landscape. There is no tree, however, which can take its place, or which can so quickly send up a tall, slender shaft to break a low or monotonous sky line. It became an unpleasant feature in the landscape only when it was used without judgment and without discretion.

A Wood Picture.

WE are sometimes told that Nature hides her choicest products from all but those who are willing to search for them in the more secret recesses of her great laboratory of beauty—that she spreads indifferent things before the indifferent world, and reserves her loveliest for her true lovers. But the charge is hardly a just one. Generally speaking, the most beautiful plants are not the rarest. It is truer to say that to many eyes the rarest will always seem most beautiful, simply because of their rarity.

But if we speak not of the things which grow, but of the way in which they grow—not of Nature's productions as such, but of the arrangements, the compositions, the pictures into which she weaves them—then we may confess that no one understands her power who is familiar only with roadsides and meadows and the trodden paths of the woods; and no one who, in more secluded places, takes account of the large things but overlooks the small. In the heart of the forest or the depth of the swamp or by the tangled margin of the lowly rivulet we must search amid Nature's little things to find what she can do in the way of producing varied, delicate, subtle and tender effects of beauty. One such effect I found not long ago which seemed to me to deserve description quite as much as any of the conspicuous features of the very beautiful Catskill country I was visiting.

In the heart of a moist hillside forest, chiefly composed of young Beech trees, thickly bestrewn with large boulders, and carpeted with rich patches of Fern, I found a smooth, gray trunk set close to a low, rounded rock, beside which the Ferns grew in tall, feathery tufts. The top of the rock on the side furthest from the tree sloped gradually into the ground, and was covered with green Mosses and a tangle of Strawberry vines, from which the scarlet fruit hung profusely in scattered bunches. Close to the tree the rock was bare, but in a hollow of its surface the large-flowered Wood-sorrel (*Oxalis Acetosella*) had taken root, forming a great cluster of drooping, heart-shaped leaves spangled with white, starry blossoms delicately veined with pink. A fissure in the stone began near this hollow, passed around to the front of the rock, and slanted across its face to the lower corner beneath the Strawberry vines, and all along this fissure the *Oxalis* had spread so that a garland of leaves and flowers seemed to have been thrown around the stone. No artist could have imagined anything so exquisite—could have chosen materials which contrasted so effectively yet har-

moniously in form, texture and color alike, or could have disposed them with such skill that there should not seem a leaf too many or a flower too few, a line out of place, a color too strongly emphasized, a detail of any kind that might be altered without detriment to the general effect. And what artist could have executed any idea with such delicate completeness that the closer one looked the more beauties one discovered?

It is things like these that one finds in the woods for the looking, but never finds unless one looks. Stones and Beech-trees and Ferns, Strawberries and Moss and Sorrel, are common things enough, but it is only where Nature is most quietly at home, where the foot of man comes seldom and the hand of the flower-gatherer has not trespassed, that she perfects such lovely pictures with common materials, and shows them to us in their dewy, fresh completeness. *M. G. van Rensselaer.*

Foreign Correspondence.

London Letter.

THE interest of the meeting of the Royal Horticultural Society on July 10th was centred in the new hardy plant, *Ostrowskia magnifica*, which has flowered for the first time in Europe in the nursery of Veitch & Sons. This plant has been pronounced by such men as Herr Leichtlin, of Baden-Baden, to be the finest of all the *Campanula* family, and these great expectations have been realized, as it turns out to be a grand plant, and certainly not rivaled by any other herbaceous plant of a similar description. When full grown it is from four to five feet high, with the fleshy root-stock of many other campanulaceous plants. The short stems rise erect as straight as a gun barrel, and the large, sessile leaves are arranged in whorls at intervals of a few inches. Surmounting each stem is a huge flower, fully six inches across, in form like a shallow cup, and deeply divided into eight lobes. The color is a delicate mauve, traversed with a network of pencilings and veinings of a deep purple, while here and there the color deepens. The flowers look at first sight more like those of a large Clematis than a *Campanula*, and it is scarcely credible that such a plant is hardy. Lovers of hardy flowers are in raptures about it, and a brilliant future is predicted for the plant. The vote for a first-class certificate to it was unanimous in committee. It comes from central Asia, in the Turkestan region, and its introduction is due to Dr. A. Regel, who, above all other men, has made us acquainted with the vegetation of this comparatively unknown region.

Among the new Ferns, one named *Gymnogramma Pearcei robusta*, is the embodiment of elegance, and is perhaps the most delicately beautiful of the genus. This variety is remarkable for a stronger growth than the type, and is so different that one would not be likely to confuse the one with the other. The fronds are cut very finely, and being of a peculiar shade of bright green are most attractive. This was shown by Messrs. Veitch. A crested form of the well-known green-house Fern, *Pteris tremula*, was deservedly admired. Every one knows how graceful the original is, and though this new sport does not gain in elegance, its tasseled pinnæ give it a singular appearance. As the fronds are long and recurve, it is thought to be highly ornamental, and one that will take with the market growers.

Messrs. Veitch again showed a large collection of their new seedling green-house Rhododendrons of the Javanese group, and the committee selected for a certificate a very beautiful sort called *Souvenir de J. H. Mangles*. The flowers are very large, compared with older sorts, of good shape and color, and of thick texture; they are a lovely salmon-orange.

Messrs. Paul had splendid blooms of their new dark Rose, Grand Mogul, which already holds a high place among deep crimson Roses. It is as fine as A. K. Williams

in form, is very full and of good build. The color is of the deepest and richest, and the perfume very sweet and powerful. Duchess of Albany is a sport from La France, and differs in no way from the old sort except in a greater depth of color.

Allium Pedemontanum, the finest of all the ornamental Onions, was beautifully shown by Mr. Ware, of Tottenham, and though an old plant now, it had never before been exhibited in such perfection. Nobody would take it for an Onion, so very unlike one are its drooping heads of bell-shaped flowers of a rich, deep violet purple, which, moreover, are devoid of the objectionable garlic odor that accompanies others of the genus. It comes from Piedmont, and no doubt it is quite hardy in America, where it will be considered, no doubt, among the choice bulbs for the rock-garden.

There are few American visitors to London interested in gardening who do not pay a visit to Mr. Cannell's nurseries at Swanley. It is one of the few great nurseries in this country where soft wooded plants of all kinds are grown exclusively. They are for the most part green-house plants, and some of these are grown on a large scale. There is now a bewildering array of plants in the height of their flowering season, but undoubtedly the leading attractions are tuberous Begonias, single and double Pelargoniums, Cannas, Gloxinias and Fuchsias. The Begonias are truly wonderful, and though we are accustomed to see the cream of the new varieties at the Royal Horticultural exhibitions, one can have no idea from these of the effect of a great houseful. The race of Swanley Begonias is remarkable for sturdy and compact growth, enormous flowers, in outline as near a circle as possible in a Begonia, and yet Mr. Cannell says he shall not cease raising new sorts until he can strike a true circle with a compass from the centre to the outer edges of the petals. The colors, too, are as remarkable as the growth, for the entire gamut of tints, from the most brilliant scarlets and the deepest crimson to pure white and clear yellow, is represented, and yet this dissatisfied nurseryman will not rest contented till he gets a blue or a purple Begonia. The half tones are to me the most charming, especially those in which there is a mixture of yellow and scarlet, or, as some call the tint, yolk-of-egg color. In a new group recently raised and appropriately called "Picotee edged" the petals are white or some delicate tint, with a strongly marked edging of rich color, such as crimson. Others, again, have scarlet crimson or pink petals with a conspicuous white centre. I am afraid I shall be accused of exaggerating if I state that I measured some of the single Begonias and found they covered over six inches of my rule, and some of the double ones which look more like Pæonies than Begonias, are over five inches across and make dense globular masses of petals like satin rosettes. There are perhaps more admirers of the double than the single varieties, but for effect in a mass the former are not in it compared with the latter as any one may see at Swanley with houses full of each side by side.

Another class of plants in full blow at Swanley is the hybrid Cannas. These are quite new to most people, who will scarcely believe that such a glorious race of plants have evolved from such insignificant material as the old Indian Shot (*C. Indica*). Probably other species of *Canna* have been used by the hybridist in the production of this new race. These Cannas have flowers as large as those of a *Gladiolus*, and on account of their irregular flowers, they pass very well for Orchids in a cut state. The colors are very strange. Odd mixtures occur among them, such as bright yellow spotted with crimson, Indian or Venetian red edged with yellow, crimson flaked with orange, and such like combinations. I could pick out from the Swanley collection a score of varieties in which these strange colors occur, and all the plants bear noble foliage and are very floriferous. The houseful of Cannas had a very fine effect, as the large leafage, itself of various shades of green and purple, acts as a foil to the tall spikes of brilliant hued

flowers. The Cannas are planted in free soil (not in pots) in a warm, moist house, and the luxuriant growth and abundant bloom show that such is the proper treatment. Mr. Cannell catalogues the new hybrid Cannas as the "coming plants," and I believe he is not far wrong.

London, July 20th.

W. Goldring.

New or Little Known Plants.

Magnolia hypoleuca.

OUR illustration on page 305 is the first which has been published, with the exception of that in the Japanese book quoted below, of this handsome *Magnolia*, one of the largest, and the most northern of the eight species found in Japan, and, economically, the most useful, probably, of the entire genus. *Magnolia hypoleuca** is a common tree in the rich forests which cover the mountains in the southern part of the northern Island of Jesso. Here it attains a height of sixty feet or more, with a trunk diameter of nearly two feet. In habit, if we may judge from the largest plant in this country, it more closely resembles *M. macrophylla* than any other American species, with the same erect trunk covered with smooth, pale bark, and the same wide spreading branches. The stout brown branchlets are conspicuously marked with the round leaf-scars and narrow, stipular rings; and the large, pointed, glabrous leaf-buds resemble those of the North American *M. Umbrella*. The leaves are alternate, or somewhat sub-verticillate toward the ends of the branches; they are broadly obovate, a foot or more long, six or seven inches wide, obtuse, or sometimes shortly cuspidate, rounded at the base, and borne on stout petioles an inch and a half long. They are dark green and glabrous on the upper, pale and covered on the lower surface with short, scattered, white hairs, which are longer and more numerous on the prominent mid-rib and twenty to twenty-four principal veins. The creamy white flowers exhale a delicious fragrance, which may be described as a combination of those of Wintergreen (*Gaultheria*) and of Banana fruit; they are six or seven inches across when fully expanded and appear in New York late in May or early in June. The leathery, petaloid sepals and petals are obovate-spathulate, rounded, or sometimes slightly cuspidate. The stamens and carpels are imbricated on a short, thick receptacle, the brilliant scarlet filaments adding materially to the beauty of the flower. The fruit, which I have not seen, is described by Siebold and Zuccarini as elliptical in form.

The wood of *Magnolia hypoleuca* is straight-grained, easily worked and dull yellow-gray in color. It is the wood commonly used by the Japanese in the manufacture of objects to be lacquered; it is preferred for sword-sheaths, and the charcoal made from it is used in polishing lac.

Magnolia hypoleuca was first sent to this country in 1865 by Mr. Thomas Hogg, and planted in his brother's garden in Eighty-fourth Street by the East River, in this city, which for many years was the most interesting spot in the United States for lovers of Japanese plants.

This tree is now twenty-eight feet high, with a trunk thirty-one inches in diameter three feet from the ground; and it will be a misfortune if the improvements now being made in that part of the city necessitate its destruction.

The northern and elevated range of this species, and the fact that Mr. Hogg's specimen has grown so rapidly in an exceedingly bleak and exposed position, seem to indicate that this tree will prove hardy in the Northern and Middle States. It has been largely propagated by Mr. S. B. Parsons, at Flushing, Long Island. We are indebted to the Superintendent of Central Park for the specimen from which our illustration was taken. C. S. S.

Cultural Department.

The Vegetable Garden.

VEGETABLE gardening is very well done around Boston and the gardeners there try to have everything of the best. Just now, in early August, Tomatoes are beginning to ripen, Peas are moderately plentiful, Celery has been planted

out, and of Beans, Corn and root crops there is a full supply. Charles Sander, gardener to Professor Sargent, maintains a capital succession of vegetables. For Sweet Corn he uses Cory for early, and Crosby's for the main crop. He grows more of Livingston's Perfection Tomato than of any other. He is partial to Dewing's Turnip Beet and claims to get an even strain of red-fleshed roots. My experience has been different; I have always had some crimson-red and others a good deal banded

with white. Although white or striped-fleshed Beets may taste as well as crimson fleshed ones, they do not look as well upon the table, and therefore should not be used. For Snap Beans he uses Mohawk, Valentine and Black Wax. For Onions, Silver Queen, Red Globe and Yellow Danvers. For Celery, White Plume and Boston Market. He earths up White Plume to make it tender, and sprouts Boston Market to confine it to a single head. Nearly all the private gardeners grow Boston Market to one head, and grow it for a main crop. Now this is a troublesome way. Golden Heart is just as good a Celery as Boston Market and it generally confines itself to one heart and by using it we do away with much of the labor spent in sprouting. But Boston Market keeps best of all Celeries; we usually have it till the end of April. Market gardeners usually plant Celery in single rows, private gardeners often in double rows and in trenches a few inches under the ground level. Mr. Robinson, of Easton, had his Celery on the level, because he thinks this a preventive of rust. But no matter whether it is planted on the level or in shallow trenches rust will appear, and where land is dry and sandy it is essential to plant in shallow trenches to help retain moist-

covers the canes with earth in winter, and with this treatment finds it hardy enough. He would be willing to confine himself to Sharpless and Belmont for Strawberries, the latter being the best in quality.

Glen Cove, N. Y.

Wm. Falconer.

The Plum.

THE cultivation of the Plum in some sections of the country when confined to the foreign varieties, is getting to be quite as precarious as that of the Gooseberry, and hereabouts, at least, it is more uncertain than that of the Peach. If the trees grow they produce a crop of black knots. If they bloom freely and set a full crop of fruit it too often rots before it ripens. We only manage to save the fruit by canning it as soon as it approaches maturity. And yet the time was when the older of the improved varieties, such as Washington, Jefferson and Yellow Egg, yielded good crops, while Damsons and Blue Gages came up in our yards spontaneously and bore abundantly. If this Plum rot is due to a fungus similar to the Grape rot we might discover some remedy or employ the

Hardy Bulbs Blooming in the Grass—See page 302.

ure, for the great point in Celery growing is to keep it moist and in vigorous growth from the time the seedlings appear till the plants are stored for the winter.

Mr. Sander considers Fother's Champion Erfurt one of the best Cauliflowers. Sown about the first of February, and grown along in pots, then planted out in spent hot-beds, twelve plants to a three by six foot sash, he begins cutting Cauliflower early in May. Veitch's Autumn Giant does not do well with him. It does very well here and gives good heads from October till January. Of course if it has not hearted before frosty weather sets in it is lifted and heeled in close in cold-frames.

Mr. Sander finds Christiana the best of all Musk Melons; it never fails to bear and ripen a heavy crop of fruit. He saves his own seed from the finest early fruit. About New York Christiana is a most uncertain variety, seldom of any good whatever with us. Hackensack is our most reliable variety, but it is a large, coarse melon. Emerald Gem has been very satisfactory for the past few years. Surprise is our best red-fleshed melon.

Mr. Sander grows Cuthbert and Brinkle's Orange Raspberries. The latter is somewhat tender, but he lays down and

same or similar means to stamp it out. Here is a good subject for our mycologists to study.

Until the growing of choice Plums is attended with less risk than at present, it is well worth while to pay some attention to our native varieties, of which the Wild Goose is the most prominent and widely known. Its advent was heralded with great promises, but so many different types have been palmed off on fruit-growers that the results have been more varied than satisfactory. The general complaint was unproductiveness, and this was finally attributed to defects in the flowers, and the remedy proposed was to plant it among other kinds that would supply the deficiency in pollen. My original tree stands among a number of other kinds amply able to furnish all needed pollen, and yet it has never been more than fairly productive, and this year is almost an entire failure. The fruit is of an attractive scarlet color, an inch and a quarter in length, with a cross diameter a trifle shorter. It is not a very desirable dessert fruit, but does very well for cooking and preserving. Other trees, sold under the same name, bear fruit not more than half the size. The name Wild Goose is therefore no guarantee as to what the fruit will be.

From sources apparently trustworthy we hear of native varieties much superior to the best of those we have grown under the name of Wild Goose, and it would not be surprising if our best and most reliable Plums were in time developed from this native stock. I have tested but one other Plum of this class, the Reed, which originated at Hightstown, New Jersey, some years ago. It is a splendid scarlet or crimson fruit, perfectly round, and about an inch in diameter. It is also a regular and abundant bearer, so much so that I have counted on a crop in advance with certainty until this season, when, for the first time, it has failed. Like the Wild Goose, it is not of first quality, and will not compare with Bevey or Green Gage, but it is better than no Plums at all. Mr. J. W. Kerr, of Denton, Maryland, has about forty varieties of these Plums on trial, according to the Delaware *Farm and Home*, and among them are some of much promise. Near Carbondale, Pennsylvania, some years ago, I saw profuse crops of Plums in many orchards. The trees were all seedlings, I was told, that came up spontaneously, reproducing themselves with little or no variation. They were of the Damson type in size and color, and it was said that the crop was not an unusual one.

Here seems to be a field for the enterprising hybridizer. If a dash of blood from some of our choicest kinds could be worked in with our sturdy native stock, a strain of this fruit, better adapted to our soil and climate, or, at least, better able to repel the attacks of fungus-disease than any we now have, might be produced.

Montclair, New Jersey.

Ferns for Basket Culture.

WHILE the use of Ferns for decorative purposes has largely increased of late years, and especially for house decoration and as an adjunct to cut-flower arrangement, yet there are many most interesting species which seem to have been neglected, or rather have not received the amount of attention they deserve. Some of these are particularly adapted to basket-culture, and it is hard to find a more graceful or beautiful object than a well-grown Fern-basket, be it filled either with one variety alone, which is the best plan, or with several sorts. Some Ferns are more attractive when grown in this manner than in any other, as their habit of growth is exhibited to much better advantage when suspended from above. One or two examples from the charming family of Maidenhair Ferns should lead the list.

Adiantum ciliatum is decidedly one of the best fine-growing basket Ferns we have. Its gracefully arched pinnate fronds are from twelve to fifteen inches in length, slightly pubescent, and sometimes pinkish when very young. The fronds of this species, like those of *A. caudatum*, which it somewhat resembles, are proliferous at the apex, and consequently when the young plant appears on the frond it should be pegged down so as to encourage it in rooting, and in this way the entire surface of the basket may soon be covered. *A. dolabriforme* is another excellent sort for basket use and very distinct in appearance, having pinnate fronds from one foot to eighteen inches in length, the rachis being black and shiny in the full grown fronds. The color of the pinnæ varies from a delicate green in the young fronds to very dark green in the matured growth. *A. dolabriforme* is also proliferous, and a rapid grower, so that a good specimen may be soon obtained. Another genus of Ferns, several of whose species make good subjects for basket culture, are the Davallias, the following being among the most useful for this purpose. *D. dissecta*, a well-known and free-growing variety with tripinnate fronds from one to two feet in length; *D. pentaphylla* is also a very handsome and distinct species, having glossy green pinnate fronds from ten to twelve inches long, which by their bright appearance give a charming effect to the plant. It is an evergreen, and though a native of the Malay Islands does very well in a temperature of fifty-five to sixty degrees. Another very pretty sort is *D. Tyermannii*, when well-grown. It has tripinnate fronds from six to eight inches in length, dark green in color when full grown, but in a young state the fronds are often marked with silvery pink.

Among the stronger growing Ferns suitable for basket work, we may mention *Nephrolepis pectinata* and *N. tuberosa*, also the "Stag's Horn Fern," *Platycerium alcorni*, the strange growth and oddly shaped fronds of which are always interesting. All of the above list are of free habit and easy cultivation, and may readily be grown in a temperature of from fifty-five to sixty degrees.

Their chief requirements are shade and an abundance of water when well established. As to soil, a compost of equal parts of light loam and peat with a fair proportion of sand and a little broken charcoal will be likely to give a good result.

Whitewash for Rose-beetles.

REFERRING to Mr. Pearson's experience in fighting Rose-beetles, as related in a late issue of GARDEN AND FOREST, let me present some notes of an experiment undertaken by Mr. E. A. Dunbar, an extensive fruit-grower of Ash-tabula County, Ohio. Last year he sprayed his Peach-trees with Paris green mixtures, of various strength, when the Peaches were half grown, to stop the ravages of the Rose-bug, continuing, in some instances, the application until the foliage was half killed and dropped off; but the bugs were not diminished, and seemed rather to thrive on the poison. Hand-picking was tried, but with unsatisfactory results.

Early in June, this year, I advised him to try spraying his Grapes and Peaches with a mixture of a peck of air-slaked lime to a barrel of water, putting it on so thick that the foliage and fruit would be well coated with lime when the water evaporated.

In a letter, written July 23d, Mr. Dunbar says: ". . . A thorough application of the remedy advised was undoubtedly the means of saving many dollars' worth of fruit. . . . The Rose-bugs appeared this year about June 12th. One application of a coal-oil emulsion to a few Grape-vines and Rose-bushes killed most of the bugs which were there, but others soon filled their places. I then mounted a Field force-pump on a forty-gallon cask, set on a stoneboat, and slaked about a peck of lime for each barrel of water, and the motion (of the boat) kept the lime in suspension. One man worked the pump, and another directed the spray, on one side of one row of Grape-vines at a time, as fast as the horse walked down the row, and we soon had the vineyard thoroughly whitewashed, and the lime well on the fruit under the leaves. I was disappointed at first in apparent results, as the bugs continued to be quite numerous, but after a few days they vanished, having hurt the Grapes very little, and I have a heavier crop than for several years past. Few Rose-bugs had attacked the side of my Peach-orchard nearest the house, and therefore I did not visit the further side for several days. When I did the bugs had already destroyed many Peaches. I at once whitewashed the Peach-orchard in the same manner as the vineyard, with the exception of one row, and the bugs all emigrated to that row in the course of a day or two. The whitewash showed quite plainly after several hard rains, and one application was sufficient."

I think the effectiveness of the application would have been increased had a small quantity of crude carbolic acid been added to the lime-water. No danger to the foliage need be apprehended from the application of any amount of lime. At this station this season I have had the fruit and foliage of some Plum-trees thoroughly coated with lime for weeks, and they appear even brighter and healthier than those not treated in this way.

Ohio Agricultural Experiment Station.

Clarence M. Weed.

Gentians are plants that should be more generally grown. Nearly all are hardy, as far as enduring cold goes. They merely need enough cover to prevent them from being heaved out by alternate freezings and thawings as the winter breaks up. All need a moist subsoil. Though they succeed well in deep loam, a little peat seems to be beneficial to such species as *G. verna* and *G. Bavarica* and two or three other alpine species.

Gentians are impatient of removal or division. I have failed more than once in trying to establish *G. Burseri*, *G. lutea* and *G. punctata*, all grand yellow-flowered species, from the European Alps. The finest specimen of *G. lutea* I ever saw measured five feet high when in bloom. It had been planted in peaty loam, with brick rubbish added, when a seedling, and had taken three years to mature sufficiently for blooming. Most Gentians are slow in reaching the flowering stage. *G. cruciata* and *G. affinis* will sometimes flower the first year from seed. *G. Pneumonanthe*, *G. asclepiadea* and *G. septemfida* require two years.

In order to insure the germination of Gentian seed, it had better be sown in the fall, and wintered over in a frost-proof frame. The time it will take to come up is uncertain. Seed of *G. septemfida* sown in the fall, will germinate fully the following spring, but if kept dry until spring and then sown, it will come up in a straggling way all summer long, and will not fully germinate until the next spring. So it is with most of them, some even requiring three years for seed to germinate. *G. cruciata* and *G. affinis* are the only species, so far as I know, which will germinate quickly after being sown in spring.

G. Pyrenaica and *G. verna* are at home in moist meadows, and seldom do well in cultivation if removed from the grass

which forms the turf in which they grow naturally. *G. Bavaria* is a swamp species, growing and flowering beautifully if the ground is kept spongy with water, and it is the gem of all the dwarf species. The ultramarine blue of its flowers cannot be surpassed. The lovely *G. Karroo*, from the Himalayan mountains, is the only one which seems partial to shade.

These notes embrace most species in cultivation, but there are many other beautiful species, and varieties of those named above.

T. D. Hatfield.

Wellesley, Mass.

Sweet Peas.—Of the new varieties of Sweet Peas sent out this season the following have come under my notice: Autocrat, Caprice, Autumn Tints, Venus, Beauty, Apple Blossom, Boreaton, Blue Bird, Johanna Theresa, Capt. Sharky and Tricolor. Of these, Apple Blossom, Boreaton, Capt. Sharky, the variety under the two names, Blue Bird and Johanna Theresa, and Splendor, seem to be distinct. Autocrat is identical with Indigo King, Caprice with Princess Beatrice, Autumn Tints with

many seedsmen. Sometimes old varieties are sent out under new names, and it is worse than annoying to pay for Peas at the rate of two cents and a half each, and then find that the same variety can be bought for twenty-five cents an ounce.

Newton Highlands, Mass.

A. H. Fawkes.

Cattleya Bowringiana.—This *Cattleya* has not received the attention due to it, although it is one of the finest introductions of late years. Its blossoms are chaste and very beautiful, fifteen of them being often borne on a single spike and that during the winter months, when Orchid flowers are scarce. The sepals and petals are mauve-tinted rose, the lip being of a rich crimson and the throat yellow. It is a native of Guatemala, where it is found growing luxuriantly on the bare rocks, enjoying full sun the greater part of the year. Very little compost, therefore, is needed about the roots of the plant, but a good supply of air and light should be given its period of growth.

Anguloa uniflora.—This fine *Anguloa* was discovered by M.

The Victoria Tank at "Sandyside," Yarmouth.—See page 309.

Orange Prince, Venus with Vesuvius, Beauty with Invincible, Carmine and Tricolor with Capt. Clark.

Apple Blossom, as grown here, does not agree with the introducer's description, which was, "An improved Painted Lady." It is a large, fine flower of a rosy carmine color, edged and blotched with white. Boreaton is very distinct and fine. The standard is broad and smooth, of a dark bronzy color, with darker veins, the wings are purple shaded bronze. One of the finest dark Peas grown, Blue Bird or Johanna Theresa, has a fine, large flower, with bronze standard, and bright, bluish-purple wings and flowers freely. Capt. Sharky is a good variety, which seems to be a sport from Painted Lady. The standard is exactly the same as in the latter, but the wings are rosy carmine. Splendor is indeed a splendid variety, with very large, fine flowers of a deep carmine-rose color. It is one of the very best.

The trade-names of Sweet Peas are very confusing, and some varieties are sold under three or four different names by as

Linden when collecting in the mountains of Colombia. It is an Orchid of very easy culture, producing its white blossoms with the young growths during the months of June, July and August, and they remain in perfection (if placed in a cool temperature) for nearly a month. They are so fragrant that a small plant will fill the house with perfume. During growth all *Anguloas* require copious waterings, and as they are liable to become infested with scale, this pest should be closely watched. Should no signs of this insect appear, they can be kept off by dipping the plants occasionally, say once a month, in a weak solution of tobacco-water.

Oncidium macranthum.—This handsome Orchid, owing to the difficulty in obtaining sound specimens, will always remain, more or less, a rare plant. Its bulbs being soft, decay very quickly when packed in the close cases used for its transportation to this country. It makes a fine Orchid for exhibiting, producing large blossoms in the early spring on very long spikes, often measuring six to eight feet in length,

each individual flower being fully three and a half to four inches in diameter, and of a bright olive-brown and yellow color, remaining in perfection for two or three months. It enjoys a very moist and cool atmosphere, being found at a very high elevation in its native habitat. Imported plants of this *Oncidium* require very little water until new roots appear, or they will decay very quickly. Good drainage, with fresh sphagnum and fibrous peat, are essential to the best results.

A. D.

Plant Notes.

The Victoria Regia.

OUR illustration on page 308 represents the Victoria tank in Miss Simpkins' garden in Yarmouth, Massachusetts, where, under the direction of Mr. James Brydon, tropical Water Lilies are grown in great variety, and with greater luxuriance and success than in any private garden in the United States.

Besides the Victoria tank, which is thirty feet in diameter, and heated by pipes brought from a neighboring greenhouse, there is a large octagonal tank fifty feet across devoted to the cultivation of tropical *Nymphæas*, and filled during the summer months with *N. Devoniensis*, *N. Lotus*, *N. dentata*, *N. cyanea*, *N. Zanzibarensis*, and other species and varieties. Flowers of immense size are produced in this tank, in which the water is kept heated to a temperature of not less than 80° by means of pipes brought from a boiler specially devoted to this purpose, and to heating a small tank-house used for keeping the *Nymphæa* roots over winter and for propagating the rarer varieties. A third and smaller tank, which is not heated, is devoted to the white European *Nymphæa* and to the pink variety of the common Eastern species, which, with the generous treatment here given to it, produces flowers which are nearly double the size of those found growing wild in the neighboring towns of Barnstable and Sandwich.

The Victoria Regia, which is rightly considered one of the marvels of the vegetable kingdom, is too well known to need any description here. It has been in cultivation for more than forty years, and flowered for the first time in the United States as long ago as 1853 in the garden of Mr. John Fisk Allen, of Salem, Massachusetts, who exhibited it that year at different meetings of the Massachusetts Horticultural Society.

The Victoria is found in the tributaries of the large rivers of tropical America which flow into the Atlantic Ocean from British Guiana to Bolivia, having first been detected in 1801 by Haenke in the Rio Mamoré, one of the upper tributaries of the Amazon, in Bolivia.

The seed from which was produced the plant which appears in our illustration was planted in January last by Mr. Brydon in a pail of rich soil, plunged in a small greenhouse tank of warm water. The young plant was shifted once, and early in June, having outgrown its quarters under glass, was planted out in its present position. The tank during cool days, or when there is a high wind, which tears the leaves, is covered with a cotton awning stretched over a frame, placed some feet above the water, the sides of this temporary structure being closed with tight-fitting shutters. Treated in this way, the Victoria will continue to produce its leaves and flowers until the middle of September, and is expected to ripen seed.

Our illustration serves to show that the stories of the wonderful supporting power of the strongly-braced leaves of this plant are not without foundation.

The Home of the Jacobean Lily.

IT is with some surprise that I hear that bulbs collected last autumn on the foot-hills of the Cordilleras of western Chihuahua, having flowered at Kew prove to be *Sprekelia formosissima*. So near our borders! The bulbs were found about six inches deep in light brown soil of ledges or rocky hills, dry situations, where the plants were not crowded upon by many other

species. Buried at this depth it is very likely that the bulbs are out of reach of frost. The plants were in leaf throughout the autumn, and grew sometimes singly, often in clumps, sometimes even in beds, which, at flowering time, probably when the first rains come early in July, must be a brilliant sight.

C. G. Pringle.

Quisqualis Indica.—This beautiful Indian climbing plant—the Rangoon Creeper—although introduced into cultivation early in the century, is now rarely seen in gardens, in spite of the fact that it is one of the very best of all warm greenhouse summer-flowering climbers. It has simple, bright green, strongly veined, sharply pointed leaves, four or five inches long, and axillary and terminal racemes of thirty to forty flowers. They have a long, slender, green, tubulous calyx, three to three and one-half inches long, and a spreading corolla of five petals, an inch and one-half across. The petals are pure white when they first expand, turning a bright orange-red the second day. As the flowers open in succession, each cluster contains both white and red flowers, which contrast beautifully with each other and with the brilliant foliage. The flowers last a long time when cut, and are admirable for decorative purposes, especially in the evening, as few flowers light up better than those of the *Quisqualis*; and it is remarkable that florists have so long neglected this plant. It does not bloom freely when the roots are confined in a pot, but when planted out in a rich border with plenty of room, it will soon cover a space twenty feet square, and produce bushels of flowers from June until October. After the flowering period it should be cut back hard to the old wood; and as it does not start to grow again until towards spring, it does not shade or interfere with the plants placed under it in winter. It is absolutely free from all insect pests. There is a second species, *Q. parviflora*, from Natal, which is not in cultivation.

Quisqualis is formed of two Latin words, *quis*, who, and *qualis*, what kind, a name bestowed upon the plant because botanists were for some time in doubt to what family it belonged. It is now considered a member of the *Combretaceæ* represented in the North American Flora by two littoral trees of semi-tropical Florida, *Conocarpus* and *Laguncularia*.

D.

Clematis Davidiana is a free-flowering, herbaceous species from northern China and Mongolia, with stems two to three feet high, large foliage and sessile axillary clusters of pale blue, tubular, deliciously fragrant flowers, which continue to appear from the 1st of August until frost. They last a long time when cut, and are esteemed by the few persons who know this plant for indoor decoration, on account of their peculiar color and for their fragrance. This, as well as two other closely related autumn flowering, herbaceous Clematises, *C. tubulosa* and *C. stans*, are well worth the attention of florists with a summer and autumn trade.

C.

Notes From the Arnold Arboretum.

THE Sumachs, as the different pinnate-leaved North American species of *Rhus* are popularly called, are all valuable ornamental plants. *Rhus venenata* is the first to bloom, its drooping racemes of inconspicuous flowers appearing in June. This is the most virulently poisonous plant found in the United States. It has much beauty, however; and the coloring of its autumn foliage surpasses in brilliancy that of almost every other native plant, and makes it late in the season the chief ornament of many swamps in the Northern and Eastern States.

The Poison Sumach is followed a few weeks later by the great Stag-horn Sumach (*R. typhina*), a small tree, widely and commonly distributed through Eastern North America; and one of the most ornamental of all American plants in foliage, in flower and in fruit, and especially in the coloring it assumes in autumn. It is not often planted in this country, for the reason, perhaps, that people rarely bring into their gardens the wild plants, which they see in their daily walks, but in Europe, especially in Germany and in France, it is seen everywhere—in city squares and parks, about the railway stations, and in the gardens of the rich and of the poor. And next to ubiquitous Locust (*Robinia Pseudacacia*), it is the American plant which now finds most favor in the eyes of European planters.

The flowers of the Stag-horn Sumach are followed by those of the Smooth Sumach (*R. glabra*), which is blooming just now. It is a handsome shrub, with smooth and glaucous branches; smooth leaves, consisting of many narrow leaflets, which are pale on the lower surface, and immense terminal panicles of yellow-green flowers. It is found on rocky or

barren soil, and is the smallest of the American species, rarely rising to a height of more than ten or twelve feet. There is a variety of this species (var. *laciniata*) now frequently seen in gardens, in which the leaflets are deeply laciniately cut and divided. It was discovered many years ago in the woods in Chester County, Pennsylvania.

The flowers of the Smooth Sumach will be followed in ten or twelve days by those of the so-called Dwarf Sumach (*R. copallina*), which may be distinguished from the other American species by the winged margins of the leaf-stalks, and by the brightly shining upper surface of the leaflets. This plant is dwarf only in name, or rather only at the North, where it sometimes covers extensive tracts of sterile, gravelly soil; but at the South, and especially west of the Mississippi River, the Dwarf Sumach becomes a considerable tree, surpassing the other species in height and in the size of its stout trunk. This is a variable species, especially in Texas towards the southwestern limits of its distribution, where botanists recognize one or two well-marked varieties.

The Button Bush (*Cephalanthus occidentalis*) is in flower. It is a stout shrub with erect branches, eight or ten feet high, with ovate or lanceolate, pointed, pale yellow-green leaves, and conspicuous spherical pedunculate heads of small, white fragrant flowers which remain in bloom for a long time. This is a widely distributed plant, from the Atlantic to the Pacific, and in Eastern Asia, growing in low wet ground, often submerged, along the borders of streams and ponds. It grows well, however, in common garden soil, although it will be found most useful when it becomes necessary to plant low, wet and undrained pieces of ground, where it will harmonize well with Alders, dwarf Willows and other water-loving plants.

The last of the *Spiræas* in flower is the Hardhack or Steeple Bush (*S. tomentosa*), familiar to all northern eyes. It is a handsome plant, which, were it not so common, would be more often seen in gardens. *S. tomentosa* has erect stems, twenty or thirty inches high, covered, as well as the lower surface of the ovate serrate leaves, with a dense brown tomentum, and terminated by a dense panicle of short, crowded racemes of small, bright rose-colored or rarely white flowers. It is found in low, swampy ground, where it spreads rapidly by underground shoots; it is not particular, however, about soil, and thrives as well when transplanted to the garden or to dry uplands as in wet ground.

The flowering of *Spiræa tomentosa* is preceded by only a few days by that of a white-flowered form of *S. Japonica*, often met with in gardens under the names, *S. callosa alba* and *S. callosa Indica*. It is a useful dwarf hardy shrub, remaining many weeks in flower and probably of Japanese or north China origin. It has erect or slightly spreading, somewhat grooved and angled, dark chestnut-brown stems, twenty to thirty inches high, lanceolate, sharply pointed, deeply serrate reticulately veined leaves, dark green above, pale and quite glabrous below. The rather small corymbs of small white flowers on the extremities of lateral branches form a wide and somewhat racemose corymb, often a foot or more across.

The late and long continued blooming period of this plant makes it a valuable addition to the list of hardy summer flowering shrubs.

August 6th.

7.

The Forest.

Farmers and Forestry.

IN no branch of agriculture, perhaps, do the people of the United States so need instruction now as in all matters relating to the care and improvement of the woods and woodlands connected with farms. It is almost a universal custom with American farmers to neglect this part of their property, and to be satisfied if the wood lot furnishes a little pasturage to their stock and a scanty supply of half rotten or worm eaten wood for the kitchen stove. The following article upon this subject, which is reprinted from a recent issue of the *Canadian Horticulturist*, is full of wise suggestions, as valuable to the farmers of the United States as they are to those of Canada:

"The study of forestry for the purpose of preserving those small remains of our wild woods now left on most farms will probably be the first practical attention given to the subject. When so little is known of forestry it is not surprising that every farm owner has a different theory, not distinct enough, however, to make many of them take any real care of their wood lots, or to say anything about it unless applied to.

"It is generally admitted that the forests ought not to be pastured, and there may be a few lots from which cattle are excluded; but I have not heard of anything more being done, and it would be hard to say what should be the next advice to farmers or forest owners. I notice in the last report on prize farms in Ontario, it is said that on one of the best of them the wood lot was cleaned up and carefully seeded to grass, and that, since the farm has been drained, the black Ash trees are dying. This is a management which seems contrary to all principle of forestry, as far as concerns the growth and life of the trees; for the first requisite in forest life is to keep the ground fully shaded—so much so that grass cannot grow—to keep it moist and free from packing, or the tracking of cattle, and to encourage such a growth that drying winds may not enter.

"It seems to me that as soon as a wood gets so thin that grass is seen its effectual growth is done, and it would pay better to cut off one or more acres and convert into good meadow land, and if need be to plant out an acre of old field with seedlings from the same or other forests.

"I do not find in the best forests more than fifty large trees per acre, and we know that Maples or other trees at eight feet apart (680 to the acre) can be grown till they will make half a cord of wood each; and if they are thinned judiciously, or, in any case, if really in vigorous life, they will increase faster than any old forest.

"To preserve a wood lot, if the trees are only of a fair size, thick enough, and few or no dead tops showing, I think it will answer the purpose if it is fenced into one of the ordinary cultivated fields; what pasturing with cattle may occur in a rotation will not likely injure it, as they will not touch trees if they can get anything else to eat.

"If very open and exposed to winds it would be well to enclose the bush with a fast-growing hedge, and in any really open place put in seedlings till the ground is properly covered. Any enclosed wood I have seen soon gets such a growth of young trees about the margin that it is hard work to get into it, and if the main trees are not too old, will, in time, make a heavy bush.

"But I have no intention of doing this, unless, on a careful survey, the bush turns out better than it appears at a glance. After counting out the large dead tops, the swamp Elms, hollow Basswoods, and short-lived Ironwoods and Balsams, there will hardly be enough worth saving, and these woods have been overrun with stock so long that the undergrowth amounts to little. I intend, therefore, to close off the old brush gradually (keeping stock out in the meantime) one or more acres at a time, as may be needed for fuel, etc., and then in proper place for forest and shelter, or on the land inconvenient to cultivate, begin a new forest by planting out regularly just such trees as I want for fuel, manufacturing or protection, to be ready by the time the old forest has been cut away.

"If the growing trees are of a valuable kind, and the owner has skill and patience to begin and carry on a judicious thinning, an old forest can be rapidly improved, but I fancy most proprietors will leave to a thoughtless employee to do the wood cutting; and it often happens that to pick out inferior or dying scattered trees will make the wood dearer than to buy it, and it may do serious injury. I find it stated in a late Ontario report that an owner removed the worthless Elms from a lot and soon after found that he had done too much thinning, for the other, and, what he thought, valuable trees, ceased growing and soon began to fail, and, as a rule, it will be safer to depend on the new planting for the future forest, at least on such small lots as our farms will retain.

"To me it is much more encouraging, for in laying out the forest, the various trees, the Maple for fuel; the Hickory, Ash and Oak for the factory; the Cherry, Basswood and Walnut for indoor use; the Pine and Cedar for outside, I feel as if I were furnishing the property with an attraction for myself and future owners, more than by the biggest castle I could find room for on the highest hill."

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—In an upland sink-hole, more than a mile distant from the river, I have recently found the Golden-club (*Orontium aquaticum*). A careful examination of the spot showed that Indians had once lived on the margin of the little pond; and the question arises, did these people plant the Golden-club in the shallow waters before their wigwam doors? It is, I believe, strictly a tide-water plant, and the chances are slight that birds could have transported the seeds from the river or

nearest creeks, where, by the way, it is not abundant. On the other hand, it is well known that the Indians made use of the plant as food. (Vide Kalm's "Travels in North America.")

In May, 1887, I spent a few days in May's Landing, Atlantic Co., New Jersey, and while boating on Great Egg Harbor River, I suddenly came upon an island of about ten acres in extent, that was densely covered with this plant. It was in full bloom, and the tide being out, the effect was grand. At high water, neither the leaves nor flower-stalks were visible. The high western bank of the river, here, too, was once the site of an Indian village, and I have often asked myself the question, if the *Orontium* island of to-day is the outgrowth of an *Orontium* plantation of two centuries ago. Our Delaware Indians were to a far greater extent than is generally supposed an agricultural people, and to many, I am sure, it would be interesting to know how far there still remain traces of their labors in this direction. In the former instance, I am inclined to believe, we have such a trace; but so far as the island is concerned, I withhold opinion. Nothing botanically need surprise one who ever wandered about May's Landing. The single street and court-house yard of which is shaded by one hundred and twenty-one magnificent white oaks. It is called a "pine barren," but there are hundreds of acres near by that are Nature-planted gardens. Think of it! On "Children's day" the village church was decorated with fifteen hundred stalks of *Xerophyllum*.

Near Trenton, New Jersey.

Chas. C. Abbott.

[The *Orontium* is a common inhabitant of the wet and swampy borders of ponds, from the neighborhood of Point Judith, Rhode Island, southward, generally near the coast, but is by no means a tide-water plant.—Ed.]

To the Editor of GARDEN AND FOREST:

Sir.—The recent discussions in your columns concerning the value of the Norway Spruce as an ornamental tree give fresh evidence of the truth, so often repeated, that advice must be suited to localities. I have often observed the unsatisfactory, unsightly specimens of Norway Spruce in eastern gardens, especially in those near the sea-coast or about large and smoky cities, and I have as often seen admirable specimens of the tree in Michigan and some adjoining states. It is true that this tree is coarse and somewhat harsh in expression, yet it is less objectionable in these features than any other large growing, coniferous evergreen, which is suited to our general conditions. It is easy of culture, takes well to a variety of soils, and even when left entirely to itself, makes a comely and attractive tree. To be sure, it loses some of its characteristic beauty with great age, but in this respect it is not inferior to any other Conifer which has been tried in Michigan. Upon the grounds of the Michigan Agricultural College there are many handsome specimens thirty years old which show no signs of failing. These trees are forty feet high, a foot and one-half or more in diameter at the base, and perfect pyramids of dark, yet soft, green, with an attractive display of light and shade.

But these trees have not been allowed to grow unchecked. Every year or two the main branches have been clipped at the ends with a Waters' pruner, causing the pyramid to fill in and tending to preserve the richness of the lower limbs. An essential operation is thus to nip four or five inches from the pushing shoots of the Norway Spruce every June. It does not appear to be well understood that tolerably old trees of this Spruce may be rejuvenated by a vigorous heading-in. I have seen an old Spruce, which, having become scraggly, was severely cut back. This cutting took place some six or seven years ago. Four or five feet were removed from each main branch and the leader was cut off. For a couple of years the tree presented an odd appearance, but there is now no trace of the treatment to the ordinary observer.

The Norway Spruce varies greatly, fully as much as does the Sugar Maple or the Elm. It is particularly desirable for windbreaks and for single specimens at some distance from the residence. It is true that the tree has fallen in general estimation, even at the West, from indiscriminate planting, yet it has still a foremost place in the affections of our people.

Michigan Agricultural College.

L. H. Bailey.

[It is, of course, possible that the climate of the interior of the Continent may be better suited for the Norway Spruce than that of the Atlantic seaboard. Thirty years, however, do not suffice to test an exotic tree in any particular locality. Norway Spruces thirty years old in the Eastern States are often at their very best, and handsome

and attractive objects; it is not until they are from forty to fifty years old that they begin to fail here at the top and then gradually perish.

It is a good rule that the adaptability of any foreign tree to any particular climate and soil cannot be safely determined until the tree has grown continually in that climate and soil for a period of time equal to the average period of its life in its native country.—Ed.]

Periodical Literature.

In *Blackwood's Magazine* Mr. Coult's Trotter is publishing from month to month an interesting series of articles called "Among the Islands of the South Pacific." His concern is chiefly with the condition of the native inhabitants of the various groups he has visited; but incidentally he gives many charming pictures of their wild and cultivated flora. For example, in his last published chapter, on the Tongan (Friendly) and the Samoan Islands he writes: "It would hardly have occurred to us to introduce cricket if there had been no turf to play on, and yet the natives speak of the introduction (accidental) of our grasses as a grievance. One hardly understands the objection, for the grass sward surrounding a Tongan village gives it, for English eyes, its greatest charm; but their ideal of tidy surroundings is the bare ground with every green blade grubbed up. One sees a well-kept Samoan village thus treated, and no doubt, amid the tropical luxuriance of vegetation, it gives a *soigné* look, and the frequent showers prevent annoyance from dust; but it is not our idea of 'Sweet Auburn.' Other plants besides the grasses have been accidentally introduced by ships and are a very serious nuisance, spreading everywhere and taking forcible possession of otherwise useful land. The worst, perhaps, are one or two malvaceous plants (*Sida* sp.), growing from two to four feet high and so thick that you can sometimes hardly get through them. The *Canna Indica*, too, very conspicuous with its bright red flowers and covering acres of ground, only appeared in Tonga a few years ago." And, Mr. Trotter adds, two imported British plants have become very common, the little yellow *Oxalis* and the Sow-Thistle (*Sonchus*). Around many of the native houses are "enclosed gardens, fenced with Bamboos or with the Croton-oil plant, and always beautiful trees, mostly with showy blossoms, as the *Barringtonias* and *Incarpus* and *Terminalia*, besides *Coco-Palms* and *Oranges* and generally some fine spreading *Banyans*. . . . You generally find pig-sties, often overgrown and shaded with the double white-flowered *Datura*, a mass of blossom." Of the Tonga country Mr. Trotter says that it is delightful for riding and walking, as the green roads traverse the forest in all directions and "this is never quite impenetrable, much of it indeed having at one time or other been under cultivation. The monotony of color, a common reproach to tropical forests, does not exist here. Besides the variety of foliage and of blossoms, chiefly white, on the trees themselves, you have masses of varied colors—*Crotons* and *Coleus*, a profusion of *Convolvulus*, of *Clitorias* and other Peas, and Beans with stout wooden stems, . . . with many other creepers. Not the least beautiful among the trees are the varieties of *Citrus*.

Notes.

The Puritan Rose has not been planted very largely in the neighborhood of Philadelphia for next winter's supply.

It is probable that a National Orchid Society will be organized here this week, while so many lovers of these plants are in the city.

The large panicles of white flowers now so abundant on the *Hydrangea paniculata grandiflora* are in considerable demand in the flower markets of this city. The flowers are cut with long stems and arranged in tall vases, with spikes of *Gladiolus* and occasionally with the Golden Rod.

The crop of the popular Pink Pond Lilies has been unusually small this season, owing, probably, to the continued cool weather. These beautiful flowers are grown for the market exclusively in small ponds on Cape Cod, where they originated. The demand for them exceeds the supply.

A farewell dinner was given to Mr. W. A. Manda, the retiring gardener of the Harvard Botanic Garden, on August 11th, by his friends and associates in the gardening fraternity. There were many expressions of regret at Mr. Manda's departure, and of hearty wishes for his success in his new field.

Rudbeckia laciniata is a grand subject for massing by the side of brooks or lakes. It grows to the height of five or six feet. The yellow ray florets droop, while the cone-like centre is larger than that of *R. hirta*—resembling a lady's thimble. It grows wild in limited quantities near Chestnut Hill, Philadelphia.

In experimenting with some insecticides, Professor Forbes found that for Curculio on Plum; Peach or Cherry, one pound of London Purple to one hundred pounds of water was effective. When used in a ratio of one to fifty the foliage was injured, and when used in a ratio of one to 200 the curculio was not killed.

South-western Michigan has become one of the great peach-growing regions of the United States. The strip of land where this fruit finds most favorable conditions is but a few miles in width, but it extends along the shore of the lake for half the length of the State.

A Palm tree, seventy years old, four feet in diameter and sixty feet high, was lately removed from the grounds of a Mr. Saunders at Los Angeles, California, to the grounds of the Wolfskill Station of the Southern Pacific Railroad. A body of earth ten feet square and six feet thick was taken with the roots. The apparatus used was similar to that used in moving buildings.

The exhibition at Columbus, Ohio, which will celebrate the centennial of the State this coming autumn will include a collection of some 700 species and varieties of trees and shrubs planted by Messrs. Thomas Meehan & Son. None of these plants will compete for any premium, and it is to be hoped that visitors will appreciate the opportunity for instruction thus liberally offered.

The cut-flower trade lasts for only six weeks at Bar Harbor. Sweet Peas are very popular there this season, especially the light-colored varieties. Many of the stone walls surrounding the cottages are planted along the crest with Nasturtiums and other flowering vines, producing a beautiful effect. The "Pine and Palm" is one of the most artistically furnished flower-stores in the country. The cosy little office in the rear, with its great stone fire-place, is much admired.

One corner of the famous Luxembourg Garden in Paris is devoted to the cultivation of Apples, and contains an assortment of 232 varieties. About the first of November of each year the harvesting of the fruit is completed, and the Apples are divided into three lots. The lot which includes the finest fruit is a perquisite of the Prefect of the Seine; the second is given to the Val-de-Grace Hospital, and the third is sold to the restaurants of the city. The orchard is also useful as a source for grafts, which are distributed without charge.

Fine varieties of *Salpiglossis sinuata* are seen this summer in the windows of some Boston florists. The flowers of this showy Chili annual have been greatly improved of late years, especially by French gardeners. The colors, which range from dark purple and blue to clear yellow, and are variously striped, are now "fixed," and come true from seed. The plants are easily and cheaply raised, and the flowers, which last well when cut, make an attractive and very useful addition to florists' material.

On Saturday, August 11th, the Garden Committee of the Massachusetts Horticultural Society paid a visit to the beautiful estate of R. M. Pratt, Esq., at Watertown, Mass. They were conducted through the green-houses and grounds by Mr. David Allan, the head gardener, and as this is one of the best kept establishments around Boston, the visit was one of great pleasure. Among the interesting objects shown by Mr. Allan were several large trees in whose trunks or large limbs decayed cavities had been filled with elastic cement, thus excluding the air, and in every case the bark has begun to close up over the cement, with indications of health and vigor.

The La France Rose is a greater favorite with flower buyers in Philadelphia than in any other city. Rose-growers for that market like it, too, and some go so far as to say that it is the most profitable variety they can grow. There is an increase in the number planted for next winter's blooming over last year, which may have a tendency to make it cheaper. Its one fault with the grower is a liability to "black spot," which it shares with *W. F. Bennett*, *American Beauty* and *Puritan*. The Hybrid Teas are more inclined to black spot than any of the true Teas or Hybrid Remontants. Is this tendency in *American Beauty* to be taken as evidence that it, too, is a Hybrid Tea?

Lælia Eyermanii is a noteworthy acquisition recently introduced by F. Sander & Co., of St. Albans, England, and named by Prof. Reichenbach, in honor of Mr. J. Eyerman, of Easton, Pa., who is an ardent and a most enthusiastic grower of Orchids. The plant is distinct, although resembling *L. majalis*. Its flower spikes are remarkable, having conspicuous well developed leafy bracts at the base of the flower-stems. Several flowers as large as those of *Lælia Gouldiana* are borne on a single spike, with sepals and petals of a rosy purple, and lip of a rich crimson with a fine white throat. Their fragrance is very pleasant, resembling that of *Orchis coriophora*.

In these days of "decorative art" it is interesting to learn that exotic plants are said to have been first cultivated in northern Europe at Paris, for the purpose of furnishing the embroiderers of the time with new and effective patterns. Constructions of glass were used for the purpose and as early as the thirteenth century were to be found in several places beyond the Rhine. Albertus Magnus, the famous "schoolman," and Bishop of Ratisbon was accused of magic by his contemporaries on more grounds than one, but one was his ability to make plants grow and bloom in winter. In January, 1247, he entertained the King of Holland at Cologne, and a feature of the occasion was the exhibition of his forced fruit-trees and blooming plants.

A minute hemipterous insect, *Triphleps insideosus*, closely related to the chinch bug, is doing considerable injury among some of the Chrysanthemum collections near Boston this summer by piercing the ends of the shoots, causing them to "go blind" and the leaves to curl up and wither. The insects are so small and move so rapidly that it is almost impossible to see them, much less to catch them, and there seems no way to destroy them without injuring the plants. Pieces of cloth, which are kept saturated with kerosene oil, and bound around the ends of slender stakes, stuck in the ground among the plants so that the saturated cloth is about on a level with the ends of the shoots, seems to have the effect of driving away the insects, or, at least, a part of them, and may be the means of saving many flowers.

Mr. L. W. Goodell, of Dwight, Massachusetts, has flowered, this year, a plant of *Euryale ferox*, a native of India and China, and, next to its near relative, the Victoria, the largest aquatic plant known. Like Victoria, it is an annual, with spiny, strongly-ribbed, circular leaves, fully two feet across, and armed flower-stalks and calyx, but the flower is violet in color, and not larger than that of the common wild Water Lily. This plant is said to flower freely in the open air in Peking, where the climate is not unlike that of our Northern States, so that there is a chance, at the South at least, that it may become naturalized. Otherwise it will not be very often seen probably in this country, as the flowers are neither sufficiently interesting nor sufficiently beautiful to justify any great trouble or expense in raising it. They are less beautiful than the flowers of the Victoria, which many of the Nymphæas far excel in charm and beauty. Mr. Goodell exhibited sections of the leaves of the *Euryale* before the Massachusetts Horticultural Society on the 11th of August.

Those horticultural visitors to New York this week who are interested in trees should make a point of seeing the *Magnolia hypoleuca* (see page 305 of this issue) on Eighty-seventh Street and East River, and the Japanese Elm (*Ulmus parvifolia*) in Central Park near the Seventy-second Street entrance from Fifth Avenue, which was also brought to this country by Mr. Thomas Hogg. These are certainly the two most interesting exotic trees on Manhattan Island, and they have, of their kinds, no equals in size in the United States, or perhaps in Europe. Prospect Park, too, in Brooklyn, should be visited. The public have a very inadequate idea of that park which is the most beautiful in the United States, and which is considered by good judges to be the best example of a large city-park now existing. Horticulturalists will find in it many rare and interesting trees. A specimen of the green-leaved Japanese Maple (*Acer polymorphum*), near the restaurant, has no equal, perhaps, in the United States, in size. On the main drive beyond the lake is certainly the finest specimen of the rare *Acer pictum* (*A. latum* and *A. Colchicum rubrum* of some authors) in cultivation. The two Silver Lindens (*Tilia argentea* and *T. petiolaris*) are conspicuous features in Prospect Park, and may be seen there in greater profusion and beauty than elsewhere in the United States. The number of good specimens of some of the rarer Conifers in the Park is considerable also.

The Florists.

THE Florists of the United States have every reason to be satisfied with the meeting of their Association which was held in this city last week. The attendance was larger than at any previous meeting of the Association; and the attention which it received from the press and from the public of this city is certainly gratifying in its indication of the growing interest of the community in all that relates to the cultivation of plants and flowers. The papers read, and the discussions to which they gave rise, were far above the average of such productions. They show that the Florists of the United States are an active and intelligent body of men fully alive to the necessities of their business, and fully determined that if its growth of the last ten years is not surpassed in the future, it shall be by no fault of theirs. Some of the treatises were filled with practical information relating to the gardener's art, and as such, they cannot fail to be real additions to the knowledge of horticulture as practiced by men who make the gentle art furnish them with daily bread, and which fierce competition compels them to practice with strict economy in the true meaning of the word. Such papers the public had a right to expect, but at similar meetings they have rarely listened to papers of a tone as elevated and grasp as broad as that of the President, Mr. Hill, of Mr. Halliday, and of Mr. Battles, of Philadelphia, whose sensible remarks relating to the artistic aspects of the florists' business, and the necessity for greater simplicity of floral arrangements than now prevails, should be carefully read by every man in the United States whose business it is to supply the public with flowers. Mr. Hill pointed out the injustice which many raisers of new varieties of plants suffer at the hands of rivals who obtain a new variety and then, perhaps, send it out again under a new name of their own coining;—an imposition from which the public, especially that part of it which buys "new plants," suffers as well as the florists.

The earnestness of the Association in its efforts to secure a better nomenclature of florists' flowers than now exists is shown by its action in imposing upon its members an as-

essment for the purpose of creating a fund to detect and expose florists who willfully sell varieties under false names. Mr. Halliday's paper upon nomenclature points out the confusion which exists in the names of florists' flowers—a confusion by no means confined to them alone, but pervading the names of all cultivated plants. The committee appointed by the Association to revise the names of plants will doubtless inaugurate a much needed reform in this matter, at least in the case of those plants most important from a commercial point of view, and determine names which the Association, with its powerful organization and influence, will be able to impose upon the trade without very serious difficulty.

The question of obtaining from Congress the enactment of a law permitting trade-marks or copyrights to be taken out for the protection of the rights of raisers of new flowers was not brought before the Convention. The question of copyrighting new flowers is not altogether a new one, and has been discussed in different European countries at various times, as well as in the United States. The right of a man to enjoy the results of his labors is as true when the product is a new flower as when it is a new book or a work of art. The intelligence, thought and study expended in growing a new race of garden-plants or new varieties of such a race is as great as is required to produce a book; but as long as the raiser of new plants must lose all benefits of these creations of his brain as soon as he sells the first individual, and so puts it in the power of his competitors to reap the benefits which should belong to him, the principal incentive to the production of new plants does not exist. This is a subject of such vital importance to the future of horticulture, here and everywhere, that we venture to suggest to the Executive Committee of the Association that it deserves careful consideration at their hands.

The horticultural exhibition held in connection with the meeting was disappointing, and cannot be taken as an example either of the actual condition of horticulture in this vicinity or as a fair representative of the florists' business of the United States. The display of florists' materials—the tools of the trade, so to speak—was large and varied, but these are objects in which the trade and not the horticultural public are interested. Of the products of the garden there was nothing certainly to indicate that this exhibition was held in one of the largest and most important commercial centres of the world, where the trade in flowers has reached a development unknown elsewhere in modern times. Of plants there were practically none, with the exception of a well-grown and well-selected collection of Caladiums from Mr. G. W. Childs' garden near Philadelphia. Gladioli were exhibited in considerable numbers and variety, but they were the Gladioli of twenty or twenty-five years ago, and showed no trace of the brilliant blood of the new races which our hybridizers, following the lead of the French, are now creating by crossing various species of these fine flowers. The large and interesting collection of Orchid flowers sent from Mr. Kimball's garden lost much of its attractiveness and value, for the public, at least, from the fact that they were arranged without taste, and that the different varieties were unnamed. Among the small collection of fruit staged, splendid examples of Barbarosa and Muscat of Alexandria Grapes, from the garden of Mr. M. A. Osborn, of Mamaroneck, must be mentioned. Specimens of Nelumbium, from the pond near Bordentown, in New Jersey, where this plant is now fully naturalized, served to recall Mr. Sturtevant's service to American horticulture, in making the possibilities of Water-Lily cultivation known and the beauty of these flowers appreciated in this country. Lilies-of-the-Valley and Lilacs are not attractive objects in August, and, while it may show ingenuity to flower such plants in the summer, the practice is not one to be commended.

The number of made designs was smaller than might have been expected at an exhibition arranged under such auspices, and, on the whole, they were less objectionable

than such designs usually are. One or two of them showed taste and knowledge.

But the exhibition, after all, was not the essential part of the convention, and the fact that it was not a representative of horticultural progress in the United States, takes away but little from the general success of the convention, which showed that the florists of the United States are not behind any other class of business men in this country in enterprise and in intelligence, and that they realize the responsibility of their position toward the public as educators in many matters of decoration and taste.

The manufacture of cypress shingles has become, of late years, an important industry in the south and south-western States. According to statistics collected by the Southern Shingle Association, the product of the present year exceeds that of 1887 by about forty per cent., reaching a total of 520,000,000. These figures include, probably, a part of the shingles manufactured by hand, as well as most of those produced in the mills, but not all. The domestic manufacture, on a small scale, of cypress shingles, has long been a favorite occupation of the negroes and poor white people living in the neighborhood of the Cypress swamps, and the total number made in this way is large, although it is practically impossible to collect anything like complete statistics of the product of industries carried on in homes. It would be safe, probably, to add, however, several millions to the figures published by the Southern Shingle Association. No statistics, unfortunately, of the amount of cypress lumber manufactured, are now available, but that it has greatly increased of late years there can be no doubt. Each year makes the value of this remarkable wood better known and more generally appreciated, and as white pine of the highest grades becomes more difficult to obtain, cypress must replace it at the north in many employments where a light, resinous, straight-grained and very durable wood is demanded. The supply of cypress is by no means inexhaustible. The swamps of the south and south-west still contain very considerable bodies of this tree (*Taxodium distichum*), although those in the most available positions and of the most convenient size for the mills, have already been cut along the principal streams and from the neighborhood of centres of population. It is true, too, that while the Cypress only grows in deep swamps, incapable of drainage, and therefore destined to be covered always with trees, that it is not reproducing itself very extensively anywhere, and that the Liquidambar and the Cotton-Gum are gradually replacing it. The value of the Cypress, too, as a timber tree, is seriously affected by a dry-rot, a species of *Dredalia*, which is especially destructive in the great bodies of this timber, which occupy the river-swamps of western Louisiana and the adjacent parts of Texas. It is evident, therefore, that the Cypress forests are not destined to take a prominent and lasting position in the timber supply of the Continent, and that they cannot be depended upon to furnish indefinitely, or even for any considerable time, their present output. The best substitute for southern cypress to be found in any considerable quantity in the American forests, is the wood of the so-called Red Cedar of the North-West Coast (*Thuja gigantea*). It is an enormous tree, widely distributed, generally near the coast, from northern California to Alaska, where, fortunately, it reproduces itself freely, and grows, while young, with astonishing rapidity in the moist climate of the region to which it is confined.

The trees in Boston, especially the Lindens upon the Common, were greatly disfigured during several years by the hairy caterpillar of the Tussock Moth (*Orgyia leucostigma*). It has done less injury during the past two or three years, although the leaves of some Horse-Chestnut trees in the Public Garden have been destroyed by it this season, but now the trunks of many of the trees on Commonwealth

Avenue and in the Public Gardens and Common are literally covered with the white hairy cocoons of this insect. Late in the present month or early in September the mature insects will emerge and the females will deposit their eggs upon the cocoons. Next season the caterpillar will hatch, and from present appearances, unless active measures are taken now to destroy them, there will be enough to devour every leaf upon every tree in the city. Now is the time to prevent this by destroying the cocoons, which can be done easily and quickly with a brush made of stiff wires or with a sharp-pointed stick. An industrious man or boy can destroy the cocoons upon the trunks of a large number of trees in a day, and the sooner industrious men and boys are set about it, the better.

House at Honmoku in Japan.

THE photograph from which our illustration (see page 319) was drawn seemed to us of especial interest as displaying a Japanese solution of a problem very similar to that which often confronts a builder on the rocky shores of New England, especially north of Cape Cod, and on the borders of many of our inland lakes. This problem is to place a country-house on a rugged shore to the best advantage, while preserving, as far as possible, the natural character of the spot. It is only of very recent years that it has been so much as considered in this country. We have been much too anxious to imitate, under wholly different conditions, the country homes of Europe, and, in particular, of England. We have wanted to surround our houses with green lawns, well-kept flower-beds and trees symmetrical in shape and planted in accordance with the supposed laws of landscape gardening as practiced in countries all parts of which have long been subjected to cultivation. And we have too often tried to secure all this in actual defiance of natural conditions, and at the sacrifice of natural beauties which, to a really cultivated eye, would have seemed of priceless value. We have too often sacrificed the chance for a beautiful, wide outlook over the water by placing the house so far from the brink that lawns and drives could encircle it; have cut away the native growth of tree and shrubs—rough and straggling, perhaps, but picturesque and precious for that very reason—and replaced them by nursery specimens; have planted gardeners' flowers in the stead of nature's beautiful wild products, and in the end, after a vast expenditure of time, pains and money, have succeeded in producing merely a bad imitation of an English villa, unattractive in itself, and utterly out of keeping with the landscape environing it.

Fortunately, tastes are changing, and one of the chief facts to be placed to the credit of the architectural profession in America to-day is the fact that it has developed a keen sense for the diverse natural beauties of our country, and an admirable power of adapting its constructions to the site and the surroundings at the moment in question. It is getting to be recognized as a binding æsthetic rule that a house shall conform itself to site and surroundings, and that these shall not be defaced to suit the character of a design abstractly evolved on paper, or tortured into the semblance of something which foreign hands had created under very different conditions. Many American homes exist, built within the last ten years, which are as worthy of praise from the point of view of appropriateness and picturesque charm as the Japanese house in our present picture. Some of them we hope to illustrate at a later day; but the Japanese house is meanwhile shown as evidence that the most thoroughly artistic nation of the modern world endorses the idea we are trying to explain. It will be noted that this house is placed quite at the edge of the cliff, so that the most extended possible view is obtained; that every tree which could be preserved in building it has been preserved; that the wild aspect of the spot has not been interfered with, and that the constructions of man, alike in the house itself, and in the fences, steps and

other surroundings, have been kept as simple and unobtrusive as possible. Picturesqueness is not the only quality to be prized, either in architectural or in gardening art; and it is a quality which, if forced into life where it does not naturally belong, is distressing to every cultivated eye. But when nature gives us picturesqueness in so clear and pronounced a form as here, the architect must accept her leading or ruin the effect both of her work and of his own. And spots quite as distinctively picturesque as this, and very similar in character, abound, as we have said, in many parts of our pine-grown, rocky coasts, and demand analogous architectural treatment. Naturally, to advise direct imitation of a Japanese house in America is no part of our desire, yet it may be said that the general architectural idea embodied in this house is far better fitted to adaptation in this country than most of those European models upon which we have so largely drawn in the past.

Foreign Correspondence.

London Letter.

THE finest Orchid which secured a certificate from the Royal Horticultural Society at its meeting on July 24th was *Cattleya Amesiana*, from Baron Schroeder's matchless collection, and probably the largest specimen in existence of this rare plant, it having been one of the gems in Mrs. Morgan's collection dispersed at New York some time since. It is a hybrid, raised five years ago by Messrs. Veitch, of Chelsea, between *Cattleya crispa* and *C. maxima*, and in growth it resembles most nearly the first named parent, the bulbs being stout and tall. The flowers are so strikingly like those of the superb *C. Exoniensis* that the difference between the two hybrids is not readily detected. The sepals and petals are broader than those of *C. crispa*, are less reflexed, and, instead of white, are of a delicate mauve tint. The labellum is broad and shallow, and exquisitely frilled at the margin. In color it is of the richest purple-crimson on the lower part, while the upper half is pure white, which serves to emphasize the intensity of the crimson. The specimen shown bore half a dozen spikes with three and four flowers on each, and therefore well deserved a cultural commendation.

Another exquisite little Orchid certificated was *Saccolabium celeste*, from Mr. B. S. Williams. Comparing it with the well-known *S. curvifolium*, it has the same thick, channeled leaves, strongly recurved and arranged in two ranks. The cylindrical flower spikes are about four inches long, quite erect, and consist of a crowd of small flowers with sky-blue sepals and petals and a lip of rich purple-blue. It reminds one of *Vanda cerulescens* in flower-color, and is quite unique in this respect in the genus *Saccolabium*. It is supposed to come from Moulmein and was first known under the name of *Rhynchostylis celestis*.

Anguloa Ruckeri alba, though certificated, did not get a unanimous vote, as some of the committee thought it no better than *A. uniflora* and *A. virginialis*, both white flowered species. The Albino does not differ from the original *A. Ruckeri*, except in absence of color, the flowers being quite as large and of pure ivory whiteness, very beautiful, as if carved out of alabaster. The powerful spicy odor of this *Anguloa* is objectionable to some persons, while others like it. *A. Ruckeri*, var. *retusa*, was also shown by Mr. Dorman, but it does not differ much from the typical form and is not nearly so fine a variety as *A. Ruckeri sanguinea*, with blood-red flowers. Messrs. Sander, of St. Albans, showed two new Orchids, both beautiful, but scarcely in condition to show their merits. One was *Bollea Wendlandiana*, quite a new species and distinct from others in color of the flowers. In growth, foliage, size and shape of flower it resembles the old *B. celestis*, but the color is a soft lemon yellow of various shades, with not a

trace of the plum-purple tint which characterizes most of the *Bolleas*. The other Orchid was *Lælia Eyermanniana*, supposed to be a natural hybrid between *L. majalis* and *L. autumnalis*. In bulb and leaf it resembles the former, but the flower is most like that of *L. autumnalis* in size, shape and color, which is a soft mauve-pink. A very marked feature of this novelty is the bracts, which, instead of being membranaceous, are leafy and green, and I know no other *Lælia* that has this peculiarity.

Among new green-house plants the most important was a variety of Javanese Rhododendron, with snow white blossoms as large and as fine in truss as any of the numerous hybrids which Messrs. Veitch have raised and exhibited of late years. There has been no lack of varieties with flowers of all shades of crimson, yellow and pink, but a white-flowered variety has long been sought for. Now we have it, and its value cannot possibly be overestimated, as a race of white-flowered green-house Rhododendrons, which will, in time, prove a great boon to those who have to supply a demand for white flowers, especially in winter, when these Rhododendrons naturally flower most abundantly, may now confidently be expected. This novelty is appropriately named Purity.

Two new Roses won certificates, a noteworthy fact, inasmuch as the committee are always cautious in certificating new Roses. One of these was shown by Messrs. W. Paul & Son, of Waltham Cross. It is named Duchess of Albany, and is a sport from *La France*, differing in no way from that favorite variety except in color, which, in the Duchess, is several shades deeper, while its petals preserve the characteristic curl which shows the paler pink inner surface and adds so much to the flower's beauty. The committee has now had flowers of it before them at consecutive meetings and they feel confident that it is a good Rose. The other new Rose was from the other Paul's of Cheshunt, and is named Paul's Cheshunt Scarlet. It was not put forward as an exhibition Rose, but merely as a garden Rose, and is chiefly remarkable for its intensity of color, the perfect shape of the flowers in advanced bud stage, the compact dwarf growth of the bush, and its floriferousness. The flowers shown certainly bore out all the points the raiser claims for this Rose, and I am acquainted with no other whose color so nearly approaches to a true brilliant scarlet. It is no doubt a seedling from one of the vivid scarlet Roses that have had their origin in the Cheshunt nurseries.

One of the most important exhibits of the meeting in the opinion of many was the new Japanese *Stuartia Pseudocamellia*, shown for the first time in bloom by Messrs. Veitch, from their nursery at Coombe Wood, where it has proved itself hardy as the North American representatives of the genus, *S. Virginica* and *S. pentagyna*. The Japanese is a good deal like the latter in flower, but most reminds one of the North American *Gordonia pubescens*. The leaves are lanceolate, acuminate, slightly toothed about four inches long. The flowers are produced from the leaf axils and are three inches across the outspread petals, but as these do not open widely the flowers look smaller than they are. The petals are broadly ovate, ivory-white and silky on the exterior faces and therefore shine like satin. The tufts of pale yellow stamens harmonizes beautifully with the warm white blossoms. The shrub is a very free flowerer, for the twigs shown, which were only a few inches in length, bore numerous flowers. The species is aptly named as the flowers remind one of a single Camellia, and the foliage is not unlike that of the Tea plant (*C. theifera*).

Three new Ferns received certificates, two being crested forms of British species. One was named *Lastrea montana ramo-coronatus* having the pinnæ ending in a dense crest, and the end of each frond also broadly crested. The other was a crested Hart's Tongue, *Scolopendrium vulgare cristatum*, and so dense is its crest that it looks like a tuft of the finest garnishing Parsley. Both are good varieties of hardy Ferns, but whether they are real acquisitions, considering the thousand and one crested forms we already have in cultivation, I cannot say. The

third certificated Fern was the pretty *Nothocheila Muelleri*, which has slender fronds a foot in length, with rounded, olive green pinnæ, covered with brownish scales.

London, July 24th.

W. Goldring.

Mr. Kimball's Orchids.

THROUGH the kindness of W. S. Kimball, Esq., hosts of visitors have been able to see a remarkable display of Orchid-flowers in his great collection, as many as 500 names having been registered on the visitors' book in a single day. At the time of our visit we found in the Cattleya-house an abundance of flowers, and suspended from the roof was a fine example of the beautiful *Catasetum Bungeoohii*, bearing on a stout spike, eight well-developed blossoms of ivory whiteness. It is really a lovely Orchid, and one of the finest introductions of late years. The sepals and petals measure five inches across, and the lip, which is broad and of wax-like substance, is beautifully undulated; the column is peculiarly constructed, standing out boldly, and breaking the flatness which the lip would otherwise present. In the same structure is the new and extremely rare *Spathoglottis Kimballiana* in its full beauty, the brilliant blossoms reminding one of a golden-yellow *Phalaenopsis*. The plant had two fine spikes, on which were thirty flowers, many of them fully open, and presenting a very showy appearance. Another Orchid, rarely met with in such perfection, was a well-grown *Oncidium Lanceanum*, with five large spikes, bearing, in the aggregate, 100 rich-colored flowers, and emitting a delightful perfume. A superior variety of this Orchid named *O. Lanceanum (Laurencianum)* was flowering. It differs from the ordinary form in the lip, which is of a deep violet with a pure white lobe, which makes it most effective. *Oncidium Janceriense* was at home in this house, judging from the handsome, many-flowered flowers panicles seen on the plant. Its chocolate and yellow flowers have a rare attractiveness.

The Cattleyas and Lælias were in vigorous growth, the enormous bulbs having produced quantities of well-developed blossoms in all the colors, ranging from pure white to the richest purple. A gem among them is a well-flowered plant of the rare *C. Schofieldiana*, with unusually large blossoms, the sepals and petals being of a pale yellow, densely spotted with rich crimson, and a white lip with numerous violet-purple lines. Several plants of the striking, scarlet-flowered *C. superba splendens* were in bloom, as were large specimens of *C. guttata Leopoldi*, with enormous, many-flowered stems; quantities of the easy-growing *C. Gaskelliana* were here in perfection, and many fine examples of *C. Dowiana* were displaying the yellow of their sepals and petals, and the purple and orange of their lips. *C. Mendelii* was bearing full-sized blossoms out of season, with many noble plants of *C. Mossia* and the pretty *C. bicolor*.

The Lælias in this house were represented by handsome specimens of *L. elegans*; the rare *L. Rothschildiana*, the free-blooming *L. marginata* and quantities of the winter-blooming *L. anceps* were already pushing their spikes for later bloom. A plant of *Calanthe veratrifolia* among the Cattleyas carried hundreds of pure white flowers above its dark green foliage. *Phajus bicolor* was flowering with some large specimens of *Anguloa Ruckeri*, with its blood-red blossoms and the golden-yellow flowers, *A. clowesii*, and near them was the old but rare *Oncidium micropogon*, with dull chocolate and yellow flowers on erect stems.

Dendrobium Jamesianum, *D. thyrsoflorum*, *D. Farmeri* and the pretty *Epidendrum patens*, with its many-flowered spikes, formed a very attractive group. Another chaste Dendrobium, of recent introduction, called *D. hercoglossum*, was conspicuous, with quantities of rosy-pink flowers the full length of its pseudo-bulbs. This is, perhaps, one of the finest of the genus. Several plants of the new *Odontoglossum Harryanum*, with enormous blossoms, showed great variations. In many instances the ground color of the sepals and petals were handsomely veined with golden yellow. *Brassavola verosa* and *B. lineata* displayed their creamy flowers to perfection.

The splendid masses of Cyripediums, for which this collection is so famous, enlivened the house with their quaint blossoms. Amongst others were a splendid example of the rare *Cyripedium Schroderæ*, with enormous flowers; a large plant of the beautiful *C. Curtisii*, the recently-introduced *C. bellatulum*, and very many more of the rarest and most beautiful species and varieties.

In the house set apart for Vanda cultivation several remarkable kinds were blooming, including *Vanda tricolor*, with its large, bold flowers; *V. suavis* and its variety, *Roelianii*, and the large rose-flowered *V. teres*. But the most promi-

nent plant in this house was the rare *Renanthera Storei*, with eighty-four expanded flowers. Its blossoms were exceedingly beautiful, of a brilliant scarlet, each individual flower measuring fully three inches in diameter. Other Renantheras were also in bloom, including *R. hystrix* and *R. matulina*, with its lovely orange and red flowers. Here, also, near the glass, was *Phalaenopsis Reichenbachiana*, a species rarely met with except in the most select collections. In shape the flower resembles *P. Sumatrana*, the sepals and petals being creamy yellow, barred and spotted with dull chocolate. Several full-flowered specimens of *P. violacea*, with highly-colored flowers, together with *P. grandiflora* and *P. Esmeralda*, were suspended from the roof. The Saccoboliums and *Arides* occupy the same house with the Vandas. Their stout, aerial roots were spreading in all directions, indicating that the proper treatment here is provided for them. A very handsome plant of Saccobolium (*S. Plumei Dayanam*), with its rich markings; and the old, free-blooming *Arides quinquevulnerum*, with its bright magenta purple markings were noticeable.

The *Odontoglossum* house was still very gay, the heat of the past few weeks having shown but little effect upon the plants, there being in flower several broad-petalled varieties of *O. Alexandra* and the yellow-flowered *O. Schleperianum*. Here, too, was *Oncidium Limminghei*, with its numerous chaste yellow and chocolate blossoms, and a grand plant of *O. serratum*, with a spike measuring some ten feet in length. Masdevallias were also represented by the curious *M. Chimera*, *M. Reichenbachiana* and others. One of the most interesting features connected with this vast collection is a splendid group of Orchids of purely botanical interest. Here their fortunate possessor has amassed an endless variety of the most curious and interesting species, many of them unique, procured from various parts of the globe.

In the large Water Lily house few Orchids were blooming except *Lalia anceps*, having expanded blossoms, probably owing to the house being closed to gain the temperature for the giant Water Lily, *Victoria Regia*, which was growing rapidly, and in the early part of September its enormous blooms are expected to open, when it promises to be well worthy of a visit. Some very fine Nymphaeas enlivened this structure with their charming flowers, including, amongst others, *N. Zanzibarensis*, *N. cœrulea*, *N. dentata*, *N. Devonensis* and *N. odorata*. Mr. George Savage, the energetic and successful gardener, has for some time adopted the use of glazed pans and pots for the Orchids entrusted to his care. It was very surprising to see the Dendrobiums and Cattleyas especially, with their numerous roots, clinging to the outer surface of the pots, clearly indicating that glazed pots are in no way injurious to the plants. It also economizes a great amount of time and labor, their neat, clean and healthy appearance leaving nothing to be desired.

Rochester, N. Y.

A. D.

New or Little Known Plants.

Erythronium Hendersoni.

PROBABLY the handsomest of all the Dog-toothed Violets is the recently-discovered Oregon species, which is here figured. While it is as graceful in habit as the common one, the bright and strongly colored flowers are more striking and attractive in their beauty. The petals have a very dark purple and somewhat blotched centre, which is surrounded by a band of yellow, and beyond this they are pale purple. The filaments are also purple, and the anthers are brownish. The flowers vary in number from a single one to three or four, usually quite large, with the petals, which are about one and a half inches long, more or less recurved, and becoming decidedly so with age. The leaves are mottled, as in most of the species.

Aside from the coloring of the flower, this species is characterized by the peculiar form of the appendages at the base of the inner petals. These appendages differ in form in different species of the genus, and in some are wholly wanting. Here the petal is very abruptly and almost hastately expanded above the very short claw, and the angles are thickened and somewhat saccate. Toward the median line there are two sub-globose, inflated appendages, which, with the filaments, almost close the orifice of the flower. The bases of the inner petals are so broad as to be nearly contiguous. The outer are narrowed

more gradually downward, and are wholly naked.

Another character to be noted is simple, club-shaped style, bearing a very shortly three-lobed and somewhat cup-shaped stigma. This character it has in common with two other species (*E. citrinum* and *E. Howellii*) of the same region, the common eastern *E. Americanum*, *E. propullans* of Minnesota, and an unnamed Texan species, otherwise much resembling *E. albidum*. All our other species have linear stigmas, including the eastern *E. albidum*, *E. purpurascens* and *E. Hartwegii* of the Sierra Nevada, and a confused group of several imperfectly known species common in the mountains from Montana and northern Colorado to the Pacific. These cannot be clearly defined until they have been carefully studied from living specimens. All are worthy of cultivation.

E. Hendersoni is a native of the mountains of south-western Oregon, where it was first collected in 1887 by Mr. L. F. Henderson, of Portland, and Mr. Thomas Howell, of Arthur, Oregon. S. W.

Cultural Department.

Cultivation of Native Ferns.—I.

IT is the purpose of this series of papers to consider the cultivation of native Ferns which are hardy or nearly so in the region about Boston.

The Ferns considered, embrace all those found in New England and therefore most of the species found in the Middle-Atlantic and North-eastern States. A few native species not found in New England are included, as they are of interest to the horticulturist and are nearly or quite hardy.

The only work on the cultivation of Ferns published in this country is an instructive little book by Mr. John Robinson, entitled "Ferns in their Homes and Ours" (1878). This book treats of the cultivation of Ferns indoors and out, their propagation, classification, life-history, etc. It contains references to the literature of the subject and lists of Ferns for special purposes. For descriptions and figures of native Ferns the reader is referred to Professor Daniel C. Eaton's magnificent quarto work in two volumes, entitled "The Ferns of North America" (1879-80). Both works are published by S. E. Cassino, Boston.*

The cultivation of hardy Ferns as a class, has received very little attention in this country. They are seldom grown at all, and very rarely in the variety and perfection which it is possible to obtain from this beautiful and fascinating group of plants. Some object to Ferns because they are flowerless plants. Most species do depend entirely on their foliage effects for their beauty; but these are so rich, so delicate, so varied, that Ferns may well be considered most desirable plants in a garden. The spring holds forth no greater charm for the lover of nature than the keen pleasure to be enjoyed from watching the unfolding crozier-like fronds of growing Ferns. Some are strong and woolly, soft to the touch, others are covered with chafy scales, the charm of which is irresistible, though difficult to describe; some again are smooth, some are green, others reddish-brown. Each kind is characteristic and has its own peculiar grace and beauty in the young as well as in the matured frond.

To the admirers of Ferns there is no need of upholding their desirable qualities for cultivation, but for the sake of those who are not familiar with them, a few may be mentioned. Ferns are excellent plants for filling up shady, dark and damp spots where other plants would utterly fail. Specimen plants make beautiful foliage effects. Clumps, carpets

*"Our Native Ferns and their Allies" is the title of an inexpensive book, with descriptions, but few figures, by Lucien M. Underwood, latest edition (1888). For New England species, "Fern Etchings," by the late John Williamson, is a desirable book. It is most beautifully illustrated by etchings executed by the author. Published in Louisville, Ky. (second edition, 1879), but now, it is believed, out of print. Neither of these works treats of cultivation. There are many works on British and European Ferns. Two small and desirable books to a cultivator are: (1) "British Ferns and their Allies," by Thomas Moore, George Routledge & Sons, London and New York. (2). "The Fern Garden," by Shirley Hibbard, Groombridge & Sons, London, 1870.

Fig. 50. —*Erythronium Hendersoni*.—See page 316.

or individuals, either by themselves or mixed with suitable flowering plants, especially herbaceous and native species, make most attractive features in a garden. Even the landscape gardener who seeks for large effects, cannot afford to ignore our native Ferns. Massive clumps of Ferns from two to five feet high or more, according to the species grown, may be easily obtained by good cultivation. The value of such clumps, often of truly sub-tropical effect, can hardly be exaggerated for such positions as the border of shrubberies and wooded locations.

It is popularly believed that Ferns are difficult to cultivate, requiring very special conditions and treatment. In the main this may be said to be entirely incorrect; a few kinds, which

are spoken of hereafter, require special treatment, and a few have resisted attempts to cultivate them successfully, but they are greatly in the minority. They are not only in the minority, but they comprise, for the most part, those species which are very small and unimportant to the general cultivator. Moderate sunshine is desirable for Ferns, provided it is not prolonged enough to dry up all moisture from the soil. A good, deep, moist loam, such as would be found on the north side of low buildings, fences or walls, or beneath the shade of trees that are not too absorptive of moisture, is a good place for a Fern border. In my garden the finest specimens get nearly full sunlight during the first half of the day. A six-foot board fence, as well as distant buildings and trees to the south, though not overhanging the Ferns at all, cast a shade on them in the middle of the day and in the afternoon, and help to retain moisture in the soil by shading adjacent ground.

Ferns are grateful for all the care that may be bestowed on them in the way of watering; but yet most species will do very well without it in favorable situations. The writer's Ferns, with the exception of delicate species in pots, are watered only occasionally in the hottest midsummer weather, as that attention is needed more by other plants. A border which has been under cultivation and well-enriched is the best for all but very delicate Ferns. Hardy Ferns are benefited by rich soil and thrive in borders which have been dressed for years with well-rotted manure. To copy nature is very well in attempting to cultivate plants that are difficult to grow or have resisted ordinary methods of handling, but no one should know better than a horticulturist that nature can be improved upon, and Ferns form no exception to the general rule. Give Ferns rich soil, good culture and old, well-rotted manure, or coarser manure as a top dressing in the autumn, and dug in in spring. They will respond kindly to such treatment, and well established specimens of many of the large species will become rich, luxuriant growing plants, which will compare favorably with the very finest specimens to be found growing naturally. As a winter covering for delicate Ferns in the open ground, salt marsh grass, straw or leaves may be used; for all the stronger ones, litters manure is desirable. Some Ferns, mostly the smaller and more delicate species, it is best to plant with peat or leaf mould about the roots. Such additions, though not necessary, would doubtless be advantageous to all species.

Besides those Ferns which are perfectly hardy, there are many species from the New England woods, as well as from our North-west and from Europe, which will thrive if they have an extra protection in winter, and which, on account of their beauty and interest, well repay this trouble. This protection is best given by having such species in a bed which can be covered by a cold-frame in winter. Cover late in the autumn after the ground has slightly frozen, and do not uncover except for occasional examination until the frame is entirely removed in early spring before the Ferns start. The kinds for which this and other special care is desirable will be noted in the discussion of species later.

It may be well to state what is meant by hardiness or want of it in the discussion of native Ferns. Those which live successfully in the open ground in this vicinity without any winter protection other than a slight covering, such as is commonly used for hardy, herbaceous plants, are considered hardy. There are other Ferns from warmer or more protected localities, or perhaps collected in the same locality with perfectly hardy species, which, as a matter of experience, are found to be not perfectly hardy. These either will not stand most winters, or a very severe winter, like the past one, will carry them off. The want of hardiness may be due to several causes. The first and most natural cause is that they need more warmth than our cold winters afford them in an unprotected garden. They may come from dense woods and shaded cliffs, where, naturally, a winter covering of snow protects them from the vicissitudes of changing temperature to which they are subjected in an open garden, or, again, they may be plants a little difficult to cultivate, which may be grown successfully, however, if only spared the trying period of our changeable New England winters. The summer heat is sometimes considered the cause of failure in cultivating plants, but with Ferns, if, in dry weather, sufficient water is supplied, this cause need not be considered.

Of course old Strawberry beds should not be allowed to mature a crop of weed seeds. But ploughing up the beds and replacing the old plants with new ones is generally better practice than any effort at cleaning them. Strong plants set now can be counted on for a good crop next year.

The Cultivation of Mushrooms.

OUR Mushroom-house is underground, eighty-three feet long, eight and a quarter feet wide and seven feet high. It is arched with brick, and heated by a Hitchings' base-burner boiler, and a four-inch hot water pipe along each side of the house. We endeavor to have Mushrooms from the end of October or first of November till the end of April, when maggots begin to infest the Mushrooms, and on this account, together with the warm weather, it is useless to attempt to grow them during the summer. As it takes about ten or twelve weeks from the time the manure is gathered till Mushrooms can reasonably be looked for, it is time to begin now in order to have them in November and December. In some seasons Mushrooms are quite plentiful in the pastures in September and October, but good natural crops are not always to be had, even in favorable pastures.

We use horse-manure, as fresh as can be got, and with the roughest part of the straw shaken out. Manure that has been well moistened in the stable or in the barn cellar is better than the dry manure removed from the stable every morning. Of this we have annual proof, as the best beds have always been made of manure that has accumulated in the cellar for a month before it was used. While manure from stables in which salt hay has been used for bedding should not be taken, I would use manure from stables where corn-husks, straw, hay or sawdust is used, but straw is preferable. Some growers prefer to use clean droppings, but I have never found this an advantage; some mix loam with the manure, but this has not been found of advantage here. Some books deprecate the use of manure from stables where carrots are fed, but this is nonsense, as carrots are fed here very liberally, and the manure from the carrot-fed stock raises excellent crops.

In preparing the manure, get together enough for a bed, say one-quarter or one-half cord, and have it all equally moist; if at all dry, do not hesitate to moisten it with water. Then throw it into a heap to ferment. In a few days, when the heat rises to about 120°, turn it over; at the same time shake it up loosely, and every day or two afterwards, for a couple of weeks or longer, turn it over again. The reason for turning it so often is to get rid of the rank heat, without letting the manure get "burned." When the temperature of the pile shows no tendency to rise above 120°, it is fit to use.

In private gardens there are often regular Mushroom houses, in which the beds are made upon the floor or on box shelves, one above the other, like berths in the cabin of a ship. But beds may be made in any dry cellar or shed, or under the benches in green-houses; almost anywhere, indeed, where they can be kept dry and temperately warm. Absolute darkness is not at all necessary, but shelter from windy draughts and shade from sunshine are necessary. The out-door cultivation of Mushrooms, practiced in Europe, is not practicable here as a rule.

The beds may be of any width or length convenient and about twelve inches deep. In making them, shake the manure loosely, so as to spread it evenly, then beat or tread it down very firmly. In a few days the heat will probably rise to 120° or 125°, but let it subside to 100° or thereabouts before planting the spawn.

We have used the English brick and French flake spawn; the English gives larger Mushrooms and the French whiter ones, but we prefer the bricks. When the bed is in proper condition for spawning, break up some brick-spawn into pieces about two inches square and plant these pieces into the surface of the bed, three inches deep, and in rows about nine inches apart each way. Then smooth over the surface of the bed and pack it firmly, as before. Some ten days after planting the spawn apply a coating of fresh loam one to two inches deep over the bed and beat it down smooth and firm. Endeavor to maintain a steady temperature of 60° day and night. A higher temperature may hasten the crop, a lower one retard it, but we have had, with a temperature of 160°, the best success.

Should the beds become dry, sprinkle them with tepid water, but do not give enough to soak through the soil and into the manure, or the water may rot the spawn. Ventilate very carefully, so long as the atmosphere is sweet, a little ventilation is needed. Never ventilate to reduce temperature. Avoid an over high artificial temperature; if it runs higher than 60° without fire-heat, ventilate to purify the atmosphere rather than to lower the temperature.

We gather the Mushrooms just as their gills are bursting; if not gathered until the heads are spread out they turn dark soon after being cut and are tougher and of poorer flavor than younger plants.

Robert A. Jackson

As a Mushroom bed will only last in good bearing condition for about three weeks, a succession of beds must be kept up in order to have a continuous crop. Many growers get a second crop from their beds, but I have always found it better to clear out the beds as soon as the first crop is over and replace them with new beds, than to depend upon the uncertainty of a second crop.

Wm. Falconer,
Glen Cove, L. I.

The Vegetable Garden.

An abundance of Lima and Snap Beans, Corn, Artichokes, Cauliflower, Spinach, Tomatoes, Lettuces, root crops and Melons, should now be found in every garden. And as the last sowings of Peas, Snap Beans, Corn, Carrots, Beets and Turnips have been made, and the late crops of Cabbage, Cauliflower and Celery planted, it is only necessary now to keep the ground clean and well stirred, and encourage growth as much as possible.

leaf maggot is usually very destructive in the fall, and I know of no remedy except a change of ground for the Spinach crop. The maggot generally appears in August or September and continues to infest the crop throughout the winter; during the late spring and summer months it disappears. About this time of year rabbits begin to be destructive to kitchen garden crops; they eat off newly planted Lettuces to the ground and the growing points out of the young Snap Beans; as a preventive, dust some soot or air slaked lime over the plants, when rabbits will not touch them.

Green-house Stages and Orchid Houses.—Mr. Hurnewell is reviewing the stages in several of his green-houses, replacing the old with new ones made of iron and cement. The side tables are of cement supported by T-iron along the centres of the houses the side-walls are of cement instead of brick, as is generally the case, and the stages for the plants are

House at Honmoku in Japan.—See page 314.
The young crops of Carrots and Beets by hand to about three inches in the rows and Turnips about four inches. Pull out and throw away all flowering plants of Carrots, Parsnips, Salsify and Scorzoneria. Lift Potatoes as soon as they are perfectly ripe and store them in small burlap bags in a cool, airy, but rather dark place. If the Onion crop has not been harvested attend to it as soon as it is ready. The white skinned Onions if dried out-of-doors assume a greenish color, but if dried indoors in a dry, airy shed, they retain their whiteness. Gather, cut and dry Okra pods for winter use; also young pods of Martynia and seeds of Nasturtiums for pickles. Plant Parsley in cold-frames for winter use, and thin the seedlings recently sown in frames. Put in a moderately large sowing of Spinach, using Viroflay or Thick-leaved. This sowing will give an abundance of fine leaves till November of later; the regular winter supply had better not be sown till the second or third week of September. The Spinach-

stair-step fashion and made of flat iron strips. These strips are about one and one-fourth inches wide, by one-fourth inch thick, in some cases set edgewise and about one or one and one-fourth inches apart, in others flat and about half an inch apart. While no doubt those set edgewise form the strongest stages still Mr. Harris the gardener, prefers those set flat, as they are strong enough for all ordinary purposes and much more easily painted. These stages, in the Orchid houses, have tanks of water under them both on the sides and centre of the house. The middle tank is of cement two or more feet deep, open at the top and extending all the way under the staging. A hot water pipe is also laid through it to warm the water and in this way increase evaporation. If needed Mr. Harris speaks in much praise of this plan, but some other skilled orchidists dislike it. There is a detached and deeper tank at one end of the house in which the warm water from the stage tank may be run for watering the plants.

The side tables of the cool Orchid house are of cement and trough-shaped above so as to hold a few inches deep of water. Over this a flat iron staging made of the same material as described above is laid and supported on iron rests, which are placed in the water so as to afford no chance for vermin, such as cockroaches, slugs or wood-lice, to get to the plants.

Mr. Ames' Orchid house stages are also of cement and iron, but there are no open water tanks or troughs under the plants; a coating of gravel is laid over the tables and kept moist. The luxuriant vigor of Mr. Ames' cool Orchids is a good indication of genial quarters. It is a very long, lean-to structure facing the north, nine feet high at the back, eight feet wide and four feet high in front. The pathway is three feet wide and alongside of the back wall, and the bench, which is five feet wide, is all on one level, in front. But as such a wide stage must necessarily be unhandy, recesses in the bench three feet wide by two feet deep occur, with eight feet intervals all along the pathway. The inside back wall is covered with netting to hold some sphagnum, and is kept a living carpet of dwarf Selaginella. The pathway is of cement. Ventilation is admitted all along the roof at the top, and in the front wall ventilators nine by fourteen inches occur at distances of twelve feet apart. The house is heated by steam with six rows of one and a half inch pipes under the bench. W. F.

Lenten Roses.—These are hybrids and varieties of species of Hellebore which bloom during April and May. They are far more satisfactory as hardy plants in America than Christmas Roses. A good, deep loam, partial shade, plenty of water during the growing season—April and May—and a covering of horse litter, for the purpose of protection in winter, is all they require. The flowering stem in *H. Ellebrus niger* is produced directly from the crown in the form of a one, rarely two, flowered, leafless scape. In the Lenten Roses the inflorescence is much branched; the secondary branches bear two or three flowers, and are always accompanied by almost stalkless, yet normal, leaves. The flowers are spreading, or campanulate, and vary in color from white to slaty purple, with sometimes a mixture of both, and prettily spotted. Propagation is by division, which should always be done in spring; or by seeds, sown as soon as ripe, and kept over in a cool frame to be brought into the green-house to germinate in spring. Some of the best are *H. atrorubus*, *H. Caucasicus punctatus*, *H. Colchicus*, *H. Olympicus*, *H. orientalis* and its varieties, many of which are sold under specific titles, such as, *H. orientales antiquorum*, one of the best, with flowers white, softly toned with pink and gray; *H. orientales guttatus*, white, and one of the earliest and best for cutting, being quite equal in beauty to a Christmas Rose, but not lasting so long when cut. The hybrids raised by F. C. Heinemann and others are mostly with *H. orientalis*, the seed-bearing parent and the foregoing species. The best are: Albin Otto, Commissioners Benary, F. C. Heinemann, Hofgärten, Inspector Hartweg and Willy Schmidt, the latter being robust in habit, with pure white flowers, which should make it valuable to the trade.

T. D. Hatfield.

Plant Notes.

Primula Rusbyi.

THE inquiry of an English correspondent concerning the habitat of this new Primrose prompts me to send to GARDEN AND FOREST a note on the beauty of the plant, its discovery and habitat.

Early on the morning of the 4th of May, 1881, I had left my camp at the end of a wagon road in one of the cañons of the base of the Santa Rita Mountains of southern Arizona, had mounted successive heights—the grassy slopes covered with a sparse growth of Oaks and Arbutus, the breezy ridges crowned with Pines, and the more difficult steeps dark with the Douglas Spruce—and was clambering painfully up the long, bare crest of Mount Wrightson, the monarch of that mountain group, when I was reanimated by the exclamations of delight of my young assistant, then a little in advance, over the prettiest flower he had yet seen in Arizona, as he declared. I found it to be a Primula. It was much smaller than *P. Parryi* of the mountains of Colorado, but so nearly answering to the description of that species, that I puzzled over it, as I collected it again and again on those summits, trying to learn if it was really distinct, until Mr. Greene named it and described it from

specimens collected by Mr. Rusby in New Mexico in August following.

Its habitat is the meagre soil of bare ledges and the verge and shelves of cliffs of summits of 7,000 to 10,000 feet elevation. Its range from the mountains about Clifton, New Mexico, southward along the Cordilleras certainly as far as 200 miles beyond the boundary.

The beauty of this Primula must make it a choice addition to the list of plants for rockeries, etc., and the fact that along the northern limits of its distribution it must be exposed to much freezing is a guarantee of its hardiness.

The "Sour" or "Pie Cherry," is a conspicuous object during the last weeks of July in central and northern New Hampshire, where a farm house is rarely seen without a clump of this low spreading tree or bush along the garden walls. It is a variety of the old Morello Cherry, a form of *Prunus Cerasus*. The bright red fruit hanging upon long stems is very ornamental and as the birds do not relish its acid flesh it hangs a long time. Formerly the Sour Cherry was very generally cultivated through the Middle and Northern States, but the Black Knot, to which this plant is subject, has nearly exterminated it, in spite of its habit of spreading by suckers which it throws up vigorously in all directions. According to Darlington, it had almost entirely disappeared from Pennsylvania early in the century, and it is now unknown in southern New England, although it was a common garden plant in that part of the country thirty or forty years ago. In the prairie states, too, it has had to succumb, and it is now apparently in northern New England only that this once common and familiar plant can be seen in this country. The New Hampshire plants are sometimes infested with the Black Knot, but they are often quite free from it; and there is every appearance that they will survive there many years longer. The Morello Cherry is sometimes ten or even twenty feet high, with slender, graceful branches, spreading out horizontally and forming a round bushy top. The leaves are one and a half to three inches long, on slender petioles rarely an inch long. The fruit stalks are usually solitary, sometimes in fascicles of two or three. The fruit is fleshy, acid, rarely more than a half or two-thirds of an inch in diameter, bright red or nearly purple when dead ripe. Formerly this was considered the best Cherry for cooking, and was highly esteemed in the manufacture of "Cherry Bounce." S.

Aralia Cashimera.—This is one of the noblest and most stately hardy herbaceous plants of recent introduction. It forms a mass of dark green foliage, six feet high by as much through, and in August bears narrow terminal racemes, three or four feet long, composed of numerous umbels of white flowers. The leaflets of the immense compound leaves are four or five inches long, hispidulous, sharply serrate, broadly acuminate, prominently veined, with a pale lower surface. It is a native of the mountains of Cashmere and of Afghanistan, where the botanists of the late Afghan Boundary Commission found it in the Birch forests of the Malana valley at an elevation of nearly 10,000 feet. It would be difficult to find a better subject among herbaceous plants for planting singly on the margins of a lawn or shrubbery. *Aralia Cashimera* is perfectly hardy, and may be easily raised from seed, which it produces in great abundance. D.

Shepherdia argentea.—A correspondent writing from Mandan, in Dakota, calls attention to the probable value of this plant, the Bull Berry of the settlers in the upper Missouri valley, for hedges in the severe climate of the northern plains. "The *Shepherdia* grows on the Missouri bottoms, where it is sometimes overflowed, and where it reaches a height of twenty-five feet and is somewhat diffuse; it is most abundant on the steep bluffs of streams where there is not much grass, but it appears also on the summits of some of the highest and driest buttes in this vicinity, where it is short and compact. It seems to grow slowly. Isolated clumps of these bushes are beautiful. The red berries are gathered and used for food by Indians and by whites, and are said to make good jelly." The *Shepherdia* is hardy at the east, and, when covered with its bright red fruit, extremely ornamental.

A New Rose.—In the report of the July meeting of the Belgian Botanical Society, M. Crépin gives a full account of a supposed very fine new species of Tea Rose, which has been discovered by General Collett on the mountains between Birmah and Siam. It has a pure white flower, five inches in diameter,

and differs from the common *Rosa chinensis*, Jacq. (*R. indica*, Auct.) by its single-flowered inflorescence, entire outer sepals, unarmed floriferous axis, and very large flower. It may prove to be an extreme variety of *R. chinensis*, but at any rate cultivators should look after it. It is fully described in M. Crépin's paper under the name of *Rosa gigantea*, Collett MSS.—*Gardeners' Chronicle*.

The Florists' Convention.

Extracts from Papers Read.

FROM THE PRESIDENT'S ADDRESS.

"What we need, and what our profession demands, is a training school for our children and the young men who are to follow in our footsteps, where shall be taught a scientific and technical knowledge of the things pertaining to plant life and plant growth, in their relations to soil, and heat, and water. Our need, and the need of the young men who are to follow, is such an education as will enable us to analyze soils, and to know, scientifically, their constituent parts, and their relation to the fibre and tissue of a plant; to be able to detect deleterious and injurious substances, to check and control the chemical action in soils, to adjust to a nicety the proportions of heat, food and water. Our most successful men are often confounded and amazed at their own failures, and can seldom assign an intelligent reason for the same. Often in the same house, under apparently similar conditions, with the same kind of soil, failure attends, where, in former years, was had abundant success. Instances of this kind abound on every hand, and we are all familiar with them. This need not be, for with a right education and proper training—such as I hope awaits the young men of the future—these problems, so serious and difficult to ourselves, will, to them, disappear as the dew before the morning sun. This knowledge, so desirable and important, can only be imparted by specialists and teachers devoted to such work. Industrial and scientific education is making remarkable progress the world over, and we, who have the good of the profession at heart, must see to it that it is kept abreast of the times. With all our boasted achievements in plant growing and flower production, the fact remains that it has been wrought out by an enormous waste of time and physical force. How to correct this, is the question uppermost in the minds of many thoughtful florists.

"Mr. Thorpe, in his address to you at Philadelphia, expressed a desire that at no distant date there might be established a National Experimental Garden; if to that could be united a school for the special training of persons for our vocation, where a practical and scientific education would be imparted, such an institution would prove of incalculable benefit to every member of the trade."

Mr. Hill suggested, as an incentive to experiments in hybridizing, that the Society should offer liberal prizes for new plants of American origin, and closed with some sound advice on commercial integrity, from which we quote:

"Those desiring the good of the profession, and who have its welfare at heart, have entered solemn protest against the dissemination of plants under false names. This abuse, which has grown out of avarice and a lack of moral principle, must be checked. We must not, we cannot afford to pass this matter by; the fact remains that the most unblushing frauds have been perpetrated on an over-confident public. Commercial probity, uprightness in our dealings with our patrons, is one of the things this Society must insist upon, until this blight which has fastened itself upon our calling is eliminated and destroyed. There must be no uncertain sound issue from this body of men on this particular subject.

"The renaming of plants must not be overlooked. We must hold inviolate and sacred the right of any man or woman to name the plant through whose skill, patience and care it has been produced; and not only that, but we must, by the moral force of this Society, render secure his or her right and title in the same forever. No one has the right, either through caprice or malice, to change or attach any other name save that given it by its disseminator.

"Another suggestion in connection with this subject may with propriety be referred to. Where the translated name from a foreign tongue is used, the original should follow in parenthesis. I question the expediency of using translations, but if it must be done, it is only right and proper that the original shall follow. To do this will certainly allay suspicion, and would prevent the unsuspecting from making duplicate purchases."

ROSES FROM THE GROWER'S STANDPOINT.

This was the subject of a paper by Mr. Edwin Lonsdale, of Philadelphia.—After stating that the first essential in the case was that the Rose could be profitably produced, the speaker discussed at length the value of different varieties:

"Bon Silene is a very old favorite, and is still one of the most profitable varieties in many localities. Its fresh pink color and ideal shape commends it to all flower lovers, and its productiveness will keep it on the list for some time to come. The day has gone by for high prices, of course, but it will continue in steady demand.

"Catharine Mermet commands the admiration of every one who sees it. Its delicate coloring, delicious fragrance and exquisite form has made it a deserved favorite. Unfortunately, not all of us can grow it profitably. Many admit that they are compelled to grow it, but it does not pay. It requires special treatment to bring out its paying qualities; and is very much inclined to run to blind wood if grown in too light a soil. It prefers a rather stiff, though porous, soil, for no Rose is more impatient of excessive moisture at the roots, and a night temperature of not higher than fifty-five degrees produces the finest flowers.

"The Bride is a sport from the last named variety, being identical with it, excepting in color, which is white. It has established itself as one of the best white Roses we have. Of course it does not compare with the Puritan when at its best, nor with Niphetos for productiveness; but it can generally be depended upon to bring a fair price when delivered in good condition. It has almost entirely displaced Cornelia Cook, and will hold its own for some time to come.

"Niphetos, it has been said, will be grown when all the white Roses now in cultivation have been forgotten. This is perhaps going a little too far; but it goes to show in what esteem this Rose is held, either by itself in a bouquet, or in "set" pieces, for which purpose no Rose is better adapted. For productiveness, taking quality through the crop, I think it leads them all.

"Much was hoped from the Puritan; and these hopes had some foundation; but, alas! experience has demonstrated that the majority of the many buds formed produce imperfect blooms. After the experience of last winter, it cannot be placed on the list of Roses likely to prove profitable.

"The advent of the now somewhat old and famous Perle des Jardins marked a new era in Rose culture. Hitherto Safrano and Isabella Sprunt were the standard sorts grown, with Bon Silene. Maréchal Neil was only grown in a few localities, but the Perle was accorded a place in every establishment, and it caused many florists to turn their attention to Rose growing. It will be a long time before the Perle is superseded, and, for general purposes, it remains one of the best we have. However, it is true that some of our very best growers do not find it profitable, because of so many flowers coming malformed. It is believed by some florists to require a more porous soil than most varieties do, and a night temperature of from 60° to 65°.

"Sunset is a sport from the last named and requires the same treatment. It has entirely superseded Safrano, and its offspring, Ned Falcot, and is likely to be more popular in the future than it has been in the past.

"Papa Gontier has not been in general cultivation sufficiently long for all growers to learn its requirements thoroughly, or to bring out its good qualities. That it has established itself as a favorite amongst flower buyers there is no doubt. Its long stems and good foliage would give it high rank, even if its fine color were not so desirable. The tendency to lose its leaves in winter, however, is against it, and if this tendency can be overcome it must be considered a first-class variety.

"Souvenir d'un Ami is another very old Rose and never much of a favorite as a cut flower. Its popularity is evidently on the wane in New York, possibly because of the preference for larger Roses.

"La France bounded in popular favor suddenly as a winter bloomer. Its adaptability for forcing must have been discovered about the time Mr. Bennett's Hybrid Teas were introduced, to which class La France undoubtedly belongs. It is a great favorite with all flower lovers, and, generally speaking, profitable to the grower. More than a dozen florists have told me that it has been the best paying Rose they grew. La France, and, in fact, all Hybrid Teas, under which head may be classified Duke of Connaught, William F. Bennett, Countess of Pembroke and a few others, are more susceptible to the attacks of Black Spot than the true Teas are. As a preventive of this, avoid too much moisture during cool weather. The fall months, before it is thought time to start a fire, are the worst for this class of Roses.

"No Rose ever created so much attention in this country as the William F. Bennett. The high price paid for half the stock, and the peculiar restriction placed upon it, aided in whetting the appetite of all florists, especially when its color and form were known. It has been one of the most valuable Roses introduced into our list of winter blooming sorts for a number of years. The \$5,000 paid for the Rose proved to be a good advertisement, and few of those who invested in it when first distributed ever had cause for regret. It is a hard Rose to get started on account of its free blooming tendency, but by persistent disbudding, when planted no more than three or four inches deep in rich, light soil, on a well-drained table, it is one of the most profitable varieties grown. It requires more heat than most of the Teas, and seems to improve in constitution every year.

"Madame Cuisin has had a hard struggle to gain the recognition to which it is entitled. It is a distinct type from the class generally in use for cut flowers in winter, being somewhat short in petal, and if cut too soon it has a diminutive appearance; but when allowed to get two-thirds open, at which time it is at its best, it has the appearance, to those unacquainted with it, of being ready to drop. It is, however, one of the best varieties for keeping in the whole list.

"Mademoiselle de Watteville belongs to the same class, but it is larger, and lighter in color. It is sometimes called the Tulip Rose, because the edges of the petals are tipped with a darker shade of pink. It has been planted quite extensively for the New York market, but whether it will prove a wise investment or not remains to be seen.

"American Beauty is perhaps the most remarkable Rose on the list. A Rose of its size, form and fragrance, and at the same time a perpetual bloomer, is indeed a great stride onward. Some may feel that it is more of a boon to the retailers than to the grower; certain it is that good flowers of it would never sell at wholesale for less than \$25 per hundred so long as the fires are going. It was introduced to the American public just when the large Hybrid Perpetual Roses had become fashionable, and flower buyers wanted them at all seasons of the year. American Beauty has relieved the retailers from all anxiety, for it is obtainable from January to September. A houseful of these plants, when doing well, is a splendid sight; their large, finely formed, sweet-scented, pink Roses, borne on shoots several feet high, would make even its severe European critics change their tone. It is easy to understand why it is condemned over the sea, because it is useless out-of-doors even here, and in winter time under glass, in that sunless climate, it could not open its blossoms with any degree of satisfaction. It seems to do equally well in solid beds and tables. It will stand much heat and moisture when in good health, and seems to do better the third year after planting out than the first. The plan of bending down the strong shoots seems to be the best for this Rose. It causes flowering shoots to break from the base, which generally produce fine blooms."

FROM THE ESSAY OF MR. H. H. BATTLES.

"Every person engaged in growing plants should know the first principles, at least, in botany. Last winter, while talking to a grower who had been in business all his life, as had his father before him, I asked him a few questions about hybridizing, thinking I would try to instruct myself by getting some good, practical ideas. He said "he did not take much stock in it, and thought it better to let Nature take its course and let them cross themselves." It occurred to me that an argument like this was on a par with advising faith cure to a disabled man when the most skilled and advanced surgical operation was necessary. Darwin was hardly of this gentleman's way of thinking; he made a great many experiments in hybridizing; he speaks of the seventh generation of plants, and crossing them when grown under different conditions; of the struggle for existence among them, the effect of climate on reproduction, the sleep of the plants, self-production during sleep, the influence of gravitation upon them, the power of digestion, their movements in relation to their wants and the diverse means by which they gain their subsistence. A great many of the subjects seem to be of no practical use, but putting our minds in this channel is what elevates, not only ourselves, but those with whom we come in contact, and in order to do this we must first become interested in botany. On this subject there is no better teacher than the late Professor Asa Gray, whom, it is said, no one has ever yet approached, in the rare art of making purely scientific theories and dry details popular and interesting. From his charming elementary work, "How Plants Grow," to his more elaborate "Manual," there is one simple, concise, and yet exhaustive, method of treating the

various grades of the science. Flowery rhetoric, beautiful figures, lofty speculations and romantic fancies are discarded, and in their place is a simplicity of statement, a transparency of language and an enthusiasm which lights up every page. The leading scientific men of this country and Europe have awarded the highest place in the galaxy of botanists to Professor Gray.

Now, for the dealer to know the habits and requirements of plants would be very useful and interesting; but there are other subjects which demand his attention first. He comes directly in contact with consumers, not only caters to their wants, but stimulates the demand for flowers by the judicious handling of them. Surrounded by the most beautiful colors, the most exquisite forms, and the most delicious fragrance in nature, one of the first thoughts of the dealer should be the artistic arrangement of flowers. Taste, to a very great degree, is a matter of education, and the study of color, form and position should be carefully considered; the knowledge of a few of the laws of color are absolutely essential to the intelligent arrangement of flowers."

After stating the laws to be observed in the proper mingling of various colors, Mr. Battles gave several rules for practice, like the following: "If you have a blue vase, use orange tints, if a green one, use red. If you are obliged to use flowers that do not harmonize, separate and relieve them with white ones. Be careful of reds, which are the most trying colors. It is not unusual to see an expensive design or basket in which is some choice tone of red, say a Jacqueminot Rose, where the effect is entirely destroyed by a few red Carnations or Bouvardia, which would have been much better thrown away than put into the design.

"The study of color is a beautiful and interesting one and does not lack text-books; the subject is exhaustively treated by Chevreul, 'On Color,' who is at the head of Gobelin's Tapestry works, and has made this subject a life study; also in G. Field's 'Chromatograph,' which has been modernized by J. S. Taylor, London. There is a delightful book on color, too, by A. H. Church."

THE CULTIVATION OF PALMS.

Mr. C. D. Ball, of Holmesburg, Pa., read a paper on "Ferns, Palms, and Decorative Plants," from which we take the following:

"Nearly all Palms are propagated from imported seeds, which, if obtained fresh, are not difficult to germinate. Orders should be placed early enough to insure getting new crops as soon as possible after being gathered. Some varieties soon lose their vitality, and the sooner they are planted after being received the more likelihood there will be of good results. In sowing I use five or six inch pots, filling them about one-third full of broken pot or charcoal for drainage. The soil used should be a mixture of about equal parts finely-sifted peat and loam, to which a little sand is added. The seeds can be planted thickly, almost touching each other. They should be covered with from half an inch to an inch deep, according to the kind and size of seeds, and the surface pressed firm and smooth. Then plunge the pots to the rim in cocoa-fibre in a warm house, where a fair bottom heat can be maintained. The soil should be kept always moist, but not wet, or the seeds are likely to decay before they germinate. By plunging the pots in the manner recommended it can be kept in this condition without frequent watering.

"The time required to germinate varies under different conditions and with different varieties. Some kinds, such as *Areca lutescens*, *Latania Borbonica*, *Cocos Weddeliana*, etc., usually take from one to two months before the growth shows above the surface. The young plants should not be potted off too soon; it is better to leave them until they are thoroughly rooted and the tops are well up. *Areca lutescens*, *Kentias* and some others of this type should be left until the second leaf appears. When ready they should be potted off into as small-sized pots as will contain the roots without injury. A two or three inch rose-pot I prefer, on account of the long, stiff roots made. The soil should be about the same as that used for the seeds. After potting they should be placed in a close, warm house. Yet great care must be taken in watering; the roots and foliage are tender, and easily damped off if kept too wet. The best plan is to plunge the pots in cocoa-fibre, fine ashes or something similar. A more even temperature can be maintained at the roots and the soil can be kept moist without frequent watering. A little bottom heat is of great help to the plants until they have become established.

"The second shift should not be made until they are well rooted through and somewhat pot-bound, and then to the

next sized pot only, using about the same kind of soil as before, although it is best not to sift it now. The larger pieces can be chopped up sufficiently fine to use, as Palms like open, fibrous soil. At the next shift, and from that time on, I lessen the quantity of peat to about one-third part, and add a small portion of fine, well-rotted cow manure for all the stronger rooting varieties. With most of the more rapid growing varieties the plant will now have reached the four-inch pot stage. This can be attained by proper handling in about one year from the time they were taken from the seed-pots. From now on the same precautions should be taken not to over-pot or over-water at the roots. Good drainage in the pots is always essential as the soil must be kept pure and well drained. While growing, all Palms require frequent syringing over the foliage, especially during the spring and summer months. In winter little or no growth is made and water should not be applied so liberally. About the middle of February they should be thoroughly overhauled, as this is the time they will want to move forward again. Those requiring more pot room should be shifted into a pot a size larger; very often, however, it is better to shake the old soil out and repot into the same sized pot if it is found that the roots are not perfectly healthy and there are not plenty of them. Care should be taken at every potting that no part of the stem be buried. The plant-base must merely rest on the surface of the soil. The roots should never be cut, as with some varieties it might prove very disastrous.

"During the spring and summer the growth of the year should be made, and shifting on should be done, whenever required, before fall. Plenty of moisture and heat is necessary to get a good growth, and syringing, once or twice a day, and water thrown on the paths on hot, sunny days is advisable. Sufficient ventilation should not be overlooked, as pure air is essential. Even during the summer it is often well to keep the fires going slowly, to maintain an even temperature. The houses should be kept well shaded, as Palms will not stand the full sunlight. The foliage is easily affected. A few applications of manure water during the summer will be very beneficial with most varieties.

"If wanted for fall sales they should be hardened off before that time by gradually lowering the temperature and admitting air more freely; it would not do to send them out in a soft condition."

NOMENCLATURE.

The purpose of this paper, prepared by Mr. R. J. Halliday, of Baltimore, was not to correct the botanical names of plants, but to enforce the advantages of uniform names of plants in trade.

"My idea," said Mr. Halliday, "is to correct floral nomenclature, and to abolish the high-sounding names which are bestowed on plants, so that we can understandingly buy from and sell to each other. The best way to accomplish this, I believe, would be to appoint a committee of twelve reliable men to classify and regulate nomenclature. The committee would do much towards removing existing abuses—fixing correct names in place of misleading ones. In catalogues and classifications the scientific, as well as the popular name of a flower, should be given on all occasions. The omission has been the source of much annoyance. Suppose we have a Fuchsia named *Souvenir de Prince Albert*, imported from France, under this florist's name. Some one, not satisfied with the name, changes it to *Babbling Brook*, in order to have something different from his brother florists. Is not the public deceived by such a course? *Heliotrope Madame Blomage*, imported from Europe and here re-named *Snow Wreath*, was ordered back by Cannell, of Swanley, England, who had it already under its proper name. He was so angry with us for our Yankee trick, having the plant in abundance, that he named it *White Lady*, and not a few American florists paid a fancy price for it under the latter name, although, by this time, it had become well known and cheap in this country under two other names. There are many cases similar to this. What is the proper name for *rose Ball of Snow*—is it an American Seedling, or is it *Boule de Neige*, of French origin? If the latter, I would like to catalogue it with both names, one in italics, as many persons believe this to be a new Rose. French growers say, Only one of our Yankee tricks! We do not want a bad reputation abroad. Is the *Geranium White Swan* an American seedling, or is it *La Cygne*, which I imported two years ago? If the latter, would not your committee recommend catalogues to give the French and English name in brackets?

"To remedy this, as I have said, a committee of twelve men,

of whom nine should agree before a verdict is formed, would be a step in the right direction. The beginner in the business wants authority for what he sees displayed in our catalogues and heralded over the country in magazines and newspapers. We want fewer names and more distinct kinds. Catalogues are becoming a jumble and a reduction is needed in plant names. Every florist should have the right to name his own seedling; this right should be preserved and no one allowed to re-name it and place it on the market under any other appellation. This Committee of Nomenclature which I propose should be empowered to pass on lists of plants submitted by members of the association at its annual meeting. Such species and varieties as in its judgment are entitled to the approval of the Association, should be recommended when at least nine of the members concur, and the list should be official upon approval by a majority vote of the members present at any general meeting. It should also be the duty of the committee to declare, when the same plant is sold under different names, which name shall be adopted; to make lists of Roses and other plants that are identical, although they have been known under several names, and to settle all questions brought before it as to the correct names of plants, where the name may be questioned or a dispute arise."

Convention Notes.

In his address of welcome, Mr. John N. May gave the following graphic illustration of the growth of the trade in florists in this city: "About the year 1840 Isaac Buchanan, who is still in active business, carried daily his available stock in a large basket, to be sold at what is now the head of Wall Street, and he then considered it a good day's trade to take in two dollars, while three dollars was an extra large sum for one day's sales. As late as the year 1871 two members of the firm of Pennock Bros., of Philadelphia, then, as now, the leading cut flower dealers of that city, came to New York in search of rosebuds for the Assembly ball, and, after spending three days here and visiting all the principal growers, returned with fifty-nine buds. Contrast that fact with the trade now, when the daily average of rosebuds sent to this city amounts to over 30,000, and when, instead of plants being brought to New York in baskets, more than one hundred large wagon loads are sent every market day, in the spring, to the West Street market alone, not to speak of the supply at the innumerable stands dotted all over the city."

Mr. Charles T. Starr, of Avondale, Pennsylvania, said: "Among Carnations I consider the *Century* and *Portia* the best red varieties; *Grace Wilder* leads in pink; *Buttercup* is still by far the best yellow, though several others have their strong claims, and may do best in some sections. *Chester Bride* is the finest of variegated colors, of decided character for that class, and among the white kinds we use *Kinzie's*, as the finest of late ones. Peter Henderson does well when old or early propagated plants are used, and *Snowden* when grown from cuttings made from the ends of the blooming stalks, just before they show bud. The new white called *William Swayne* seems to combine the good qualities of the two last named, and promises to be the finest white, for this section at least. Soil seems to exert such an influence on the growing of Carnations, as also does the construction of forcing-houses to bloom them in, that it will be very difficult to make a list that would suit all circumstances. Judicious experience is the only safe guide."

Mr. Benjamin Gray, of Malden, Massachusetts, said it was a happy coincidence that the kinds of Orchids profitable for florists' use are all of easy cultivation. The best sorts, easily obtainable, are *Lalia autumnalis* and *S. albida*, *Cattleya Trianae*, *Cologne cristata*, *Calanthe Veitchi*, *C. vestita rubra* and *C. vestita lutea*, *Dendrobium nobile* and *D. Wardianum*. If to these we add *Cypripedium insigne*, *C. Harrisianum*, *C. villosum* and *C. Spicerianum*, *Cattleya Bowringiana* and *Odontoglossum Alexandrae* we have a list which will give us succession of bloom from November until March, the season during which Orchid flowers are in greatest demand. The kinds named may all be grown in the same house, with the exception of the *Calanthes* and *Dendrobiums*, which require a high temperature, with plenty of water while growing, and should be kept cool, with enough water to prevent them from shriveling while at rest and until the buds are formed, when they may be brought into the house with the others, a few at a time, for succession of bloom.

In reply to the question whether propagation from blind shoots had a tendency to render plants less floriferous, Mr. James Pentland, of Baltimore, replied, "Emphatically, no, and

this after an experience of fifty years." Mr. J. N. May added, that in a recent test, he had propagated 300 plants—Catharine Mermet Roses—from blooming shoots, which were the finest and strongest he could find in his house, and also 300 plants from what is usually termed "blind wood." He continued: "Do not understand that this wood was taken from little weak shoots. It was taken from good, firm wood, with healthy foliage. As a result, I have failed to see a particle of difference in the produce of these plants. I am convinced that, so long as we propagate from good, sound wood, whether it be blind or blooming, we will get as good a plant in the one instance as in the other."

Here are a few sentences from the address of Mr. Battles which florists should remember: "When a gentleman wishes to send a very large and expensive bouquet, the salesman should advise sending the flowers loose in a box (which can be arranged prettily), that the lady may select the ones she wishes to wear. . . . A practice which is not quite extinct, is that of making handles on corsage bouquets, and covering them with tin foil; the sooner this is done away with, the better. . . . How many people have very unhappy recollections of funerals where they have been surrounded by ghastly designs and stifling odors. . . . Lettering on designs has been greatly overdone. I would advise strongly against it; often customers insist, but, if left to your taste, decide against it."

"Three years ago," said Mr. Robert Craig, "the *Latania Borbonica*, in six-inch pots, found tardy sale, in New York and Philadelphia, at 75 cents each. The increased demand for that class of plants is such that now they readily bring about twice that amount, and the supply is not nearly equal to the demand. In fact, the demand for these plants has already influenced the price in Europe. In several recent importations at least twenty per cent. has been added to the price. This is an indication that the increased use of Palms here has been felt abroad, even with vast quantities there grown. I am sure that this price and demand will continue to grow, because we cannot get these grand effects from any other class of plants."

Mr. M. A. Hunt, of Terre Haute, Ind., in replying to the question, "What varieties of Roses introduced within the last two years are worth growing for winter forcing?" said that "Almost without an exception those which gave great promise have proven failures for this purpose." He had found an exception in the case of a little Rose not very generally known, but which can be highly recommended to those who are in a position to make up their own work, though not, perhaps, for shipping for any distance. He referred to the Primrose Dame. Although not a strong grower, it is a very productive Rose, finely shaped and, either in the bud or open Rose-form, is one which is very desirable.

Halls for exhibiting plants, flowers and fruits are better, as well as more cheaply constructed, without board floors. Plants can then be arranged in groups on raised banks or in depressions of various forms best adapted to the character of the different objects to be displayed. Where green sod or moss can be easily procured a better effect can be produced than when plants are staged on tables. Besides this, water, which is always needed in abundance in such exhibitions, can be used to much better advantage with such an arrangement. For fruits and cut flowers, side tables in most halls can be neatly arranged just under the windows, in which light such things are best displayed.

Mr. Ernest Asmus, of West Hoboken, N. J., said, that among Hybrid Perpetuals for early forcing, say from December until February, light colored varieties are the most suitable. His choice of six was Anna Alexieff, Anna de Diesbach, Mrs. John Laing, Magna Charta, Achilles, Gounod and Madame Gabriel Luizet. For late forcing, the best among light colored Roses are Paul Neyron, Baroness de Rothschild, Merveille de Lyon, Mabel Morrison, Captain Christy, Victor Verdier, Marquis de Castellaine, Henry Schulthers and Ulrich Brunner; and, among dark ones, Gen. Jacqueminot, Prince Camille de Rohan, Louis Van Houtte and Baron de Bonstetten.

A good market Chrysanthemum must have a strong, vigorous habit, with branches able to sustain the flowers erect, and fine, healthy foliage. The flowers should be large and well-developed, and not more than two or three on a spray. The colors should be distinct and unique. There is a strong demand for the finest possible flowers, as compared with the smaller pompon varieties. This suggests that growers would do well to pay more attention to quality than to quantity.

A prize of \$500 was offered by Mr. Peter Henderson for the best herbarium, to consist of not less than 500 species of native plants, arranged according to their natural orders. This prize is to be open for competition to gardeners or the sons of gardeners, or to any one engaged in the trade as a grower or seller of plants, who is also a member of the Society. Mr. Henderson's offer was accepted unanimously with a vote of thanks.

Mr. John Smith, of Yonkers, gave it as his experience that slate, when used for benches, exercised no deleterious influence on plants. Indeed, plants on slate benches were much less liable to attacks from various pests than plants on benches of wood, which afforded harbor for insects and vermin, besides encouraging the growth of harmful fungi as they decayed.

Mr. Thomas Cartledge, of Philadelphia, said that only Roses with long stems and good foliage could be sold to advantage. A large and perfect flower with a short stem and poor foliage did not satisfy customers, and would not sell as readily or for as good a price as a fair or ordinary flower, well furnished with good leaves and a long stem.

"To keep down the ravages of snails among Ferns no better means can be employed than Lettuce leaves, Potatoes, or Turnips hollowed out. Perhaps Lettuce leaves are the best. The snails creep inside the leaves during the night, and remain there until morning, when they can be gathered up and destroyed."

The following officers were elected for the next year: President, John N. May, Summit, New Jersey; Vice-President, W. J. Palmer, Buffalo, New York; Treasurer, M. A. Hunt, Terre Haute, Indiana; Secretary, William J. Stewart, Boston, Massachusetts.

"The *American Florist* is a power that deserves our hearty support. It helps us, and the gentlemen connected with it deserve great credit."

The moment of spontaneous and genuine enthusiasm came when John Thorpe, the founder of the Society, was led upon the platform.

Notes.

At the meeting of the Massachusetts Horticultural Society, August 11th, Mr. B. G. Smith, exhibited a basket of fruit of the Wilson Jr. Blackberry, a variety raised by the late Judge Parry, of New Jersey, by crossing the Wilson with the Dorchester. The fruit is very large, handsome and regular, and of good flavor, although lacking somewhat the delicacy of the Wilson, which was also shown in great perfection.

The flowering of *Stuartia pseudo-camellia*, a Japanese species, in the Veitch nursery in England, referred to in our London Letter, seems to have been one of the horticultural events of the London season. This plant was distributed in this country many years ago by the Messrs. Parsons, and flowered profusely this season in the garden of Mr. Charles A. Dana, at Glen Cove, N. Y. A drawing of the flowers of this plant has been made, and will appear in a future issue.

Mr. Walter E. Coburn exhibited before the Massachusetts Horticultural Society, on the 11th of August, a collection of no less than 200 species and varieties of wild flowers, including thirty-seven species of grasses and sedges in twenty genera. These collections of wild flowers are exceedingly interesting and instructive features of the weekly free exhibition of the Massachusetts Society.

Hybrid Gladioli of the *Gandavensis* race are grown in great quantities, and generally in considerable perfection, in the neighborhood of Boston, where there are some large commercial collections. The weekly exhibition of the Massachusetts Horticultural Society (August 18th) was largely devoted to these flowers. The wet season, however, has not been favorable to them, and the exhibition fell short of those of several other years, both in the beauty of the varieties shown and in the excellence of individual specimens. The rare and lovely yellow-fringed Orchis (*Habenaria ciliaris*) was shown in great profusion and in excellent condition in Mr. Hitchin's collection of wild flowers. Another interesting feature of this exhibition was great masses of *Sabbatia chloroides*, one of the handsomest of American plants. It is common at Plymouth, Massachusetts, and at other points along the Atlantic coast, and is seen sometimes in the windows of the enterprising Boston florists. It should find a ready sale, as the beautiful pink flowers are delightfully fragrant, and remain fresh for some time when cut, while unexpanded flower buds will open in water after the plants have been gathered.

Sentimental Objections to Felling Trees.

IT hardly needs special affirmation in these pages that a fine tree or group of trees is of itself an object to admire and to preserve with reverential care. And yet cases often arise when the removal of a noble tree is demanded on grounds distinctly higher and broader than those upon which the affection and respect for it are based.

It is our frequent inability to recognize such cases for what they are, and our unwillingness to act in them even when they are clearly recognized, which prove that our attitude towards trees is sentimental and irrational. Whether a tree is or is not a fine example of its kind is a question subordinate to the broader one whether it hurts or helps the general aspect of the scenery in which it stands, whether it enhances or detracts from the beauty of neighboring things; whether, in short, it stands where it ought to stand, or, on the contrary, where something else or nothing at all ought to stand. In almost every possible case a tree is a part of a larger whole, and it is a fundamental axiom in every search for beauty that the interests of the whole must take precedence of the interests of any of its parts.

If a group of trees is incongruous in form or color, and could be made harmonious by the removal of one or more individuals, there should be no question as to their removal, no matter what intrinsic claims they may have to admiration. It may often be a difficult task to decide which ones to sacrifice; but it is a task which should be entered upon without sentimental or superstitious compunctions. A bleeding stump may almost make a heart bleed for the moment, but this is a wound that will quickly heal under the influence of the increased beauty of the trees which remain. In like manner, when a single tree or a whole group is detrimental in a wider way, when it hides a still more beautiful tree or group, or a fine middle distance, or a lovely stretch of horizon; when it hides anything which would be of distinctly more value than itself in the scene, or when it gives an uncomfortable look of crowding and of excluding air and light, it should be sacrificed. And a like result will be sure to follow—quick

forgetfulness of the vanished charm will follow upon the revelation of still greater charms.

It is impossible to take even the shortest walk abroad without seeing many places which would be vastly improved were one or more trees cut down. Yet even when the desirability of their removal is confessed by their owner, how difficult it is to persuade him to raise the axe! The house may be damp and dreary; other and perhaps still finer trees may be concealed from sight; all outlook upon a delightful prospect may be shut off; injury may be worked in a dozen different ways, and yet "because he loves the tree" it must remain. If he really loved trees and really cared for beauty in general, it would hurt him more to see the tree where it was palpably out of place than not to see it at all.

But if it were only when fine trees are concerned that this super-sentimental spirit was revealed, it would be easy, at least, to comprehend its existence. It appears, however, almost as often when the most ill-grown, feeble and ugly specimens are in question. For example, as has recently been pointed out in several letters published in these pages, hundreds of Norway Spruces, so far decayed that they are all but dead, disfigure our parks and cemeteries. No one professes to admire their condition or to believe that it has possibilities of improvement. Yet there is sure to be an outcry if a proposal to cut them is made. They are trees, and therefore sacred. The fact that the general effect would, in any case, be better without them, and that they are half-dead themselves, does not impair their sanctity or render the would-be cutter anything less than a heartless vandal.

It is the same in private grounds—one is daily driven to wonder why this or that perishing Spruce or Pine is preserved, and to accept in a spirit very far from acquiescent the answer that it is because the owner "is fond of trees."

It is quite time that unhealthy sentiment should give place to a genuine and sturdy respect for trees. There can be no true advance in the popular love for trees themselves until the public shall distinctly appreciate the difference between a fine tree and a poor one. And there can be no true advance in gardening art until we are clearly convinced that the beauty of a whole is more important than the beauty of any individual thing, and are firmly determined to act carefully and discreetly—yet boldly, too—upon this conviction.

The appropriation by Congress of \$250,000 to be used to investigate the extent to which the arid western portions of the United States can be made fertile by irrigation, and for the selection of sites for reservoirs and other hydraulic works necessary for the storage of water for irrigation and for the preparation of maps in connection with this work, is a wise and proper one. It has already passed the Senate, and will probably be agreed to in the House. There can be no question of the wisdom of this investigation. It is the beginning of one of the most important works ever undertaken by the government of the United States. It is believed by Major Powell, the Director of the Geological Survey, that fifteen per cent. of the arid region within the limits of the United States, or an area of 150,000 square miles—that is, an area equal to more than one-half of the total area of the land now cultivated in the United States—can be reclaimed for agriculture and made to produce valuable crops permanently by means of irrigation. The promoters of this scheme must bear in mind, however, that the forests which cover, more or less densely, the mountain ranges of western America, from which the water for irrigating purposes must be brought into the valleys, are natural reservoirs; that they hold back water which would otherwise cause floods and torrents which no structure of masonry will be able to withstand; and that by checking evaporation, which consumes such a large part of the rain which falls on the western

interior portions of this continent, they largely increase its value. As long as Congress permits the devastation of our western mountain-forests to go on unchecked and unpunished, efforts to secure a comprehensive and permanent system of irrigation for the western States and Territories can never succeed. Reservoirs are valuable adjuncts to the forest in maintaining a water supply for large irrigating enterprises; but unless the forests are preserved, as an initial step, permanent and valuable results cannot be hoped for.

A recent issue of the *Revue Horticole* calls attention to the great value of the little known *Iris pabularia*, the *Krisham* of Cashmere, as a forage plant. This plant, it appears, will flourish in the driest and most arid soil, and once established it cannot be exterminated. The leaves, which attain a height of twelve to sixteen inches, are eaten by cattle either green or dried, the same plant producing two or three crops of leaves in a season. It is recommended that the seeds should be shown in beds, and then that the young plants should be set very early the following spring where they are to remain. They should be planted in rows ten inches each way if the soil is very poor, and fifteen to twenty inches apart in richer soil. A thorough watering will aid the plants to make a good start, should it be dry when they are set. It is doubtful if *Iris pabularia* will prove hardy in the Northern States, but it should certainly be tested in California, and in our dry south-western region, where, as well as in Florida, it may be destined to play an important part in the rural economy of all that part of the country. Seed can be obtained from the Messrs. Vilmorin, of Paris.

The Treatment of Slopes and Banks.

IT is a common mistake, where a road or a flat surface of turf is to be formed at a different elevation from that of the adjoining ground, to give the bordering banks too nearly the form of inclined planes, and to make them too steep, as at *abc* in the diagram. Such slopes at the outset, while all about them is raw, are comparatively neat, and they can be formed cheaply by unskilled laborers, with little guidance or thought on the part of those in direction. They are objectionable, first, because it is difficult and costly to keep them in good order. On such steep slopes, the drainage is either too quick, in which case the grass upon them suffers from drought, or, on the other hand, subsoil water finds an outlet through the bank, making its surface soft and easily washed. Such a bank, therefore, needs to be protected by the best possible turf. But if the slope is in "kept" ground, it is difficult to form or maintain good turf upon it. Neither scythes, lawn-mowers nor rollers can be used to advantage, nor are manures apt to be evenly distributed upon it. Consequently, the turf soon falls into bad condition. If the ground is pastured, as is often desirable in case of a park-like treatment, cattle going up or down the slope poach and gouge it. In either case the grass soon grows in tufts, and the character of a continuous web of turf is lost. Storms wash out the soil between the tufts, and then freezing and thawing and further washings soon bring the whole surface to a sorry condition.

By lessening the inclination of the surface, difficulties of the class thus explained may be overcome. But there will remain, however, another and a more important objection to banks in the form of regularly inclined planes in most situations. They are stiff, formal and plainly artificial. Recognizing that they are so, it seems to be often supposed that the only revision of them necessary to a satisfactory result will be secured if a surface can be formed of a single, uniform, convex curved cross-section—like the front part of an upholstered, spring-seated sofa—made to meet the road or grass-plot at an abrupt angle, as one would trim down the edges of a pie before baking. (Shown by the line *de* in the diagram.) Such a slope is

really not less formal than an inclined plane. To make it less so, the top of the slope may be thrown back from its base further at some points than at others. But it will yet have a very unnatural aspect.

The reason of this is less difficult to understand than might be supposed, judging from the frequency with which such banks are seen in very costly works of landscape gardening, so-called.

A continuous body of good turf implies a continuous body of deep, friable soil. If the effect of a single rain-storm upon a body of such soil thrown up in a pile of convex section is carefully observed, it will be seen that a portion of the soil is washed out upon the adjoining level surface, obliterating the angle where the original slope met it, and making the lower part of the slope concave. (Shown by the lines *ijk* in the diagram.) The longer the bank of soil remains bare and subject to the wash of rain, the more it will spread at the bottom, and the less will remain of the original convex section.

Fig. 51.—Good and Bad Slopes.

Further than this: as a natural bank of loam rarely occurs that is of uniform consistency throughout, the action of the weather upon it will seldom produce a curved slope of the same cross-section at all points, and its outlines will, consequently, become varied and informal.

The lesson to be learned from observation of Nature in this matter is that it is a safe general rule, in making a sloping bank, to give it an "ogee" cross-section. (An "ogee" is an architectural term, meaning a moulding the upper part of which curves outward and the lower inward, or, more broadly, any reversed curve, such as "Hogarth's line of beauty," used in school copy-books for the stems of many of the capital letters. It may be illustrated, in a practical way, by grasping a thin elastic rod with one hand at each end, and then bending one up and the other down.) The line *fgh* is a regular ogee curve, the concave portion *fg* being equal in length and shape to the convex portion *gh*. As a rule, the proportions of the curve should be varied from time to time, so as to produce an undulating surface—graceful, if grace is a quality to be desired in the locality, but in all cases informal and natural. A slope may have at one place a cross section like *lmn* in the diagram, in which the concave part of the slope *lm* is shorter than the convex part *mn*, while a short distance away the slope may resemble the line *opq*, in which the relative importance of the concave and convex parts is reversed.

The diagram illustrates another principle in regard to slopes. If a broad, grassy surface had to terminate at a steep slope, falling to a road or fence, it would, presumably, be best to connect the broad surface with the steep one by means of a long convex curve, as at *mn*, completing the desired ogee slope by a short convex curve, as at *lm*. On the contrary, if the broad, grassy surface had to terminate at a steep slope rising to a fence, terrace, shrub border, or other marked boundary, the concave curve ought to predominate, as in the line *opq*. In other words, the slope,

if open and grassy, in either case ought to appear to be a part of the larger surface of turf, unless there was some obvious reason to the contrary. In making a steep slope on the downhill side of a road, there ought to be, if possible, a nearly level space between the edge of the road and the beginning of the steep slope of from five to fifteen feet, partly to satisfy the eye as to a sense of danger of accidentally driving down the slope and partly to make it appear as if the road had been built upon a natural shelf or terrace. The latter reason applies equally to a slope on the uphill side of a road. In either case, the distance and shape of the slope should be varied from time to time, taking advantage of the configuration of the adjoining ground, or of the existence of rocks or trees, as suggestions for determining where to widen the space between the slopes and the road, or to make them more gentle.

J. C. Olmsted.

Brookline, Mass.

July on the Shores of Buzzard's Bay.

COMPARED with central and western Massachusetts, this south-eastern portion of the state is, of course, deficient both in striking landscape features and in trees of noble size. One goes to Berkshire, not to Plymouth County, to find beautiful views, in the popular sense of the word, and finely developed specimens of trees of many species. Yet the true lover of landscape beauty, as well as the lover of nature's minor productions, does not fail of satisfaction here. Ours hardly looks like a sea-shore—it wears rather the aspect of the shore of a great quiet lake, for beaches are few and narrow, and almost everywhere vegetation comes close down to the salt water. But prettiness, if not grandeur, results from this fact; and even when the water is out of sight there is a great deal of charm in our moist meadows and sandy heath-like tracts, our thick, low-growing forests everywhere encircling tiny ponds or larger lakes, our ubiquitous, picturesque stone fences, and the low, unpainted gray cottages, which harmonize so well with them and with the character and tone of the landscape in general.

Our trees are few in number, and the two which are most prominent in the more westerly parts of Massachusetts—the Sugar Maple and the Elm—are wholly wanting, in a wild estate. White and Pitch Pines, Scarlet Maples, the northern Oaks, Gray Birches, a few Tupelos, an occasional Sassafras, and shrub-like Junipers—these are all we have; and few of them are of large size, for the woods are almost altogether “second growth,” and in some places clearly show by the lines of overgrown stone-wall which intersect them that they cover what were once cultivated fields. Yet here and there one sees White Pines of grand build and no inconsiderable height forming stately groves devoid of undergrowth; and in all other places the young trees compensate by their graceful habit and felicitous intermingling for whatever they may lack in size.

The real richness of the district lies, however, in its shrubs and herbaceous plants. The Heath Family rules in the land and to say this is to say enough in its praise. The place of the long-vanished Mayflower is not unworthily filled in July by the Wintergreen. Huckleberries and Blueberries of many sorts, from the tallest to the lowest, hung out their exquisite white bells by myriads all through the first part of the month, while, as the season has been a late one, the Andromeda is but just past its prime. Mountain and Sheep Laurel have both been blooming in great abundance, and the latter—after a fashion which many flowers have hereabouts and which Mr. Burroughs once remarked upon—has been deep and brilliant in color to a degree seldom seen elsewhere. The White Azalea is going, after having filled the swamps for weeks with its incomparable perfume, but Clethra is fast getting ready to fill its placé. Several Pyrolas are now in bloom, the most abundant being the Shin-leaf; the two Chimaphilas are flowering; and those who like the corpse-like Indian Pipe may find it in abundance.

These are by no means all our *Ericaceæ* nor are the *Ericaceæ* our only boast among blossoming shrubs. The four species of *Ilex*—Holly, Black Alder, Ink Berry and *I. lævigata*—are just dropping their pretty white blossoms. The *Viburnums* are covered now with green fruit which will soon grow pink on its way towards blackness, and be, for awhile, almost more effective than flowers. The Buttonbush is in bud, mingling everywhere with the Alder clumps. The day of the Elder-blossoms is not yet quite past and we have them in abundance, while nowhere could one find Wild Roses with flowers more thickly crowded or richer and deeper in hue. Two *Spiræas*—Meadow Sweet and Steeplebush—are everywhere; and, in short, the only shrub one misses for which one looks on the New England coast is the Barberry, which, common further north and also in Connecticut, seems to have passed us entirely by in its welcome work of colonization.

As for our herbaceous plants, maritime and other, their list is too long to tell, even although August rather than July is their time for flowering in greatest variety. One of the prettiest is the Spreading Dogbane (*Apocynum androsæmifolium*), with its blood-red leaf stalks, and drooping, white, bell-shaped flowers. The Tall Meadow Rue is still in bloom, and with it one occasionally finds the curiously ill-scented form of the purple *Thalictrum* (var. *ceriferum*). The Virginia Anemone occurs, but less finely developed than further west. *Lilium Philadelphicum* is just going out of flower as the great Turk's Cap Lily is coming in. A month ago the low grounds along the shore were blue with two species of Iris, and their humbler cousin, the Blue-eyed Grass. To-day they are spotted with the yellow Star Grass, and spiked with the tall white Alettris. It is a great country for Milkweeds, for Compositæ, for Evening Primroses, for Potentillas, and, of course, for Rushes and Sedges. Several *Polygalas* are now in blossom and the pretty little wild Flax. And as for Orchids, we have just had meadows pink over broad spaces with *Calopogons*, intermixed with which were spikes of the still more graceful and lovely pink *Pogonia*. Two or three greenish *Habenarias* are coming into flower, and our white one (*Habenaria blephariglottis*, var. *holopetala*) will soon be present in large quantities, together with, in lesser quantities, both species of *Goodyera*.

There is nothing new or striking, I know, in this catalogue, and perhaps its greatest interest may lie in the fact that I confess it so incomplete as to be hardly a catalogue at all—for what I wanted to show was that, unassuming though our district is, there is good reason for our liking it so well. The only thing I have to note which may be unexpected, is that in addition to the common Green-brier—*Smilax rotundifolia*—*S. glauca* grows here in great abundance, although by rights (I mean according to Dr. Gray) it should not venture further north than southern New York. Even this is hardly news, as the plant had already been found by Mr. C. E. Faxon on Blue Hill, near Boston; and even if it were news I could not claim the credit of the discovery. It would belong to a hunter of these woods whose eyes are a good deal keener than mine. It may be worth while to add that our Pines, which last year bore no seed, are this year full of ripening cones—both the White and the Pitch Pines.

M. G. Van Rensselaer.

Marion, Mass.

A Bridge in the Thiergarten, Berlin.

THE *Thiergarten* in Berlin is, without doubt, the finest large public park in Europe, and it seems doubly beautiful and valuable as it forms a veritable oasis in the flat, sandy and generally treeless surroundings of the German capital. It was laid out in accordance with the plans of Knobelsdorf, the architect of Frederick the Great, about the middle of the last century, and, in accordance with the taste of the time, partly in a formal way. An open space, peopled with many statues, which was called “The Star,” because it was the meeting point of a number of straight-lined alleys, formed its central feature. But the

largest portion of it was, nevertheless, left in forest, and the alterations subsequently effected have consistently looked towards the preservation and development of its natural charms. As it now appears, it is the model of what a great public park, to be used by the inhabitants of a populous city, should be—amply provided with spacious concourses, drives and promenades, adorned with works of sculpture, many of which are indeed intrinsically poor, but almost all well placed and appropriately environed, and yet, over the greater part of its surface, presenting to the eye a constantly varying succession of natural-seeming landscape effects. No contrast could be greater than that presented by the most formal and the most natural portions of this park. Here we have the long, straight drive, which leads from the Brandenburg Gate to the confines of the suburb of Charlottenburg, and there deep, bosky glades, wild-looking little lakes, or passages of forest scenery apparently as untouched by the hand of man as though the city were a hundred miles away. Yet there is no disharmony between part and part, for the transition from one to another is rightly managed, and instead of an impression of unmotivated diversity, we gain an impression of unity in variety.

The illustration herewith given is from a photograph which represents, not one of the wildest corners of the *Thiergarten*, yet one in which, although the work of man conspicuously appears, natural character has not been destroyed. The bridge, called the "Lion Bridge," from the figures which support it at either end, serves for foot-passengers only, and if less beautiful than some others, is interesting as showing that at least a comparative degree of beauty and an air of simplicity and appropriateness to rural surroundings are not impossible of achievement by the use of iron. The natural development of the trees has in no way been interfered with, and the vista of distant plantations, which the space between them affords, is much more beautiful than could be shown in a picture of this size. But the chief point to which we wish to call attention is the management of the water. Too often we see the streams and pools in parks brought into more or less formal shapes and bordered with a stiff line of stone or concrete; or, even when this is not the case, kept "tidy" by constant interference with the natural growth of the grasses or shrubs which border them. Formally shaped and bordered ponds have, of course, their place—as elements in a design the general character of which is formality. But when a natural landscape aspect is desired, the water should be as naturally treated as the ground. In this picture we see the results of such treatment, partly due, of course, to natural causes, but partly, no doubt, to intelligent, fostering care. No words are needed to explain how beautiful are the irregular borders of this pool, and the rich, encroaching growths of its aquatic plants. To produce, or to preserve, such effects as these, is the highest art when harmony permits them—it is the art which conceals art, and thus equals or surpasses Nature herself in the impression it produces.

Foreign Correspondence.

London Letter.

INCESSANT rains have played havoc with out-door gardens; flowers are not only later by a fortnight or more, but the crop of bloom, except on hardy shrubs, has been poor. Strawberries have been almost a total failure, and bush-fruits, especially Raspberries, are a poor crop, and insipid in flavor. A wet summer, however, is not an unmixed evil, and we shall enjoy the benefit of it next season, for out-door vegetation of every description is growing in a marvelous way. Ornamental trees and shrubs are making such growth as we have not seen for years, and large fruit trees, though, as a rule, borne down with fruit, are forming vigorous shoots,

Under glass the effects of a sunless sky for weeks in succession are not so apparent, and this is particularly noticeable in the great gardens and nurseries, where a large variety of plants is grown. Our great national garden at Kew, for instance, has been greatly benefited by the wet season, and both in the open air and in the houses I have never seen the vegetation look finer, and even at the present time, when the flower season is usually considered on the wane, the gardens beam with beautiful, rare and new plants in flower, so numerous that I shall devote the present letter to mentioning some of the most noteworthy among them.

Among the Orchids a few rarities are in bloom, the choicest and most beautiful being *Sobralia leucoxantha*, a new species of which only about half a dozen plants are said to be in the country. In growth it resembles the dwarf form of *S. macrantha*, and the flower is almost as large, being four or five inches across. The sepals are snow white, as are also the petals, which are broader, while the labellum has a circular lobe exquisitely frilled, and of a bright, clear yellow. Its flowers differ from those of the other new *Sobralia*, *S. xantholeuca*, the sepals and petals in the latter being yellow, while the centre only is white. Like its relative, the common *S. macrantha*, it succeeds well in the Cattleya house. The charming little *Phalenopsis Marie*, which was discovered by Mr. Burbidge while traveling for the Messrs. Veitch, is in bloom. It belongs to the Sumatrana section; has long, green leaves and short spikes of small flowers. Their color is white, heavily blotched with coffee-brown, and with a narrow, filose labellum stained with purple or amethyst. It is also one of the rarest species. I ought to mention the wonderful success obtained at Kew in flowering the great moth Orchid, *P. grandiflora*. A few years ago this could not be even grown in a healthy state, but now it grows like a weed and flowers abundantly. The plants are grown in upright cylinders about a foot high, made of strips of teak wood, and filled with drainage-material, with only a little compost of peat-moss and charcoal at the top for the plants to get a root-hold in. The specimens in some of the cylinders carry five spikes, with from twelve to eighteen flowers on each. This magnificent display, numbering two to three dozen spikes in all, has been enjoyed for the past two months. The little *Cypripediums* of the *niveum* group are in flower together, and one may see what affinity there is between *C. niveum*, *C. concolor*, *C. Godefroyæ* and *C. bellatulum*. Though they merge, as it were, into one another, there is no question but that they are distinct from the gardener's purpose. *C. bellatulum* is very heavily spotted, and is a rounder flower than that of the *C. Godefroyæ*, and is, therefore, at once distinguishable.

A rare *Ipomæa*, named *I. Hardingei*, is in bloom in the tropical Water-Lily house, and a very beautiful plant it is. This is said to be a hybrid, one of its parents being the common *I. paniculata*. The flowers are similar in size, color and form to those of the parent, but the leaves, instead of being digitate, are bilobed, larger and hairy. It is a rapid growing stove-climber, and is capable of garlanding a roof or pillar in a charming way.

A new water plant, *Eichornia tricolor*, is in flower at Kew for the first time. In habit of growth it closely resembles *E. azurea*, the leaves being cordate, bright green, and with swollen petioles, but the flowers are not so fine. The lower petals are rich purple, the upper ones pale blue with yellow centre, and are borne on erect spikes about two feet high. On seeing it I at once compared the flower with those of the common *Schizanthus pinnatus*, the resemblance being very striking. It is only valuable for growing with tropical Water Lilies and other aquatics.

A tropical bulbous plant, *Hæmanthus Katharinæ*, is now in full flower, and a more brilliant or imposing summer flowering bulb for the stove is not in cultivation. From the great globular bulb it sends up a stout stem bearing

numbers of broad, long leaves, and overtopping these is the huge head of flowers, like a half globe of scarlet stars bespangled with golden tipped stamens which protrude from them. It lasts in bloom for some weeks, and amidst the usual surrounding greenery of a plant-stove stands out a conspicuous object. It came from the west coast of Africa, and therefore delights in heat and moisture in its growing season. It is certainly a plant to note by those who look for brightly-flowered stove plants in August. Another highly commendable stove bulb is *Crinum giganteum*, from the same region. Its flowers, produced in an umbel of from five to eight on a stout

three or more flowers on each stem, and has been in bloom for a month past. Similar to this variety, but not so fine, is that named *eximia*, and there is another called *major*, all of which will, perhaps, in course of time, be grown in place of the old sort.

Among other flowers of the week here worth noting are the following: *Impatiens Hookeri*, the new tropical Balsam sent out recently by Mr. Bull. It is in all respects a stove plant of the first rank, easily grown, of vigorous habit and a profuse bloomer. The flowers are large and of a brilliant carmine-magenta. Like its relative, *I Sultani*, it is already largely grown in this country, and may be

A Bridge in the Thiergarten, Berlin.—See page 327.

stem from two to three feet high, are nearly six inches across, pure white and with a fragrance like that of vanilla. It is of the easiest culture, and remains in bloom for weeks. Its specific name is misleading, as there are several *Criniums* to which this would be a pigmy in size.

Of quite a different type of beauty is the *Milla biflora* from Mexico. It is a slender growing plant, with narrow, grassy foliage and wiry stems rising about a foot high and carrying one or more flowers. These are about two inches across, perfectly star-shaped, of snowy whiteness and fragrant. It is very beautiful, and lasts in beauty a long time during the present month. At Kew it is grown in pots, and treated as an ordinary half hardy bulb, as it has been found useless to plant it in the open ground. It is quite worthy of any extra attention bestowed upon it.

Another green-house bulb of surpassing brilliancy is a variety of the common *Vallota purpurea* named *magnifica*. It is altogether larger than the type in bulb and leaf, has a taller and stouter flower-stem, and flowers nearly twice the size. They are funnel-shaped, of a glowing vermilion, with conspicuous white centre. It carries

found in all the best gardens. Another of Mr. Bull's recent introductions is *Aristolochia elegans*, one of the prettiest in flower and most elegant in growth in the genus, and while most of the species are too large for ordinary houses, this may be grown as a small trained pot-plant. The peculiar shape and strange color of its flowers make it an object of interest in a plant-store. Those who want a continuous and abundant crop of cut flowers should get the Bolivian *Dipladenia (D. Bolivensis)*. Its large, funnel-shaped flowers are snow-white, with only a blotch of orange in the centres. The plant is a climber, graceful yet vigorous, and continues in bloom for weeks in succession. This and the lovely little *Passiflora Kermesina*, of which I lately made a note, are two of the best stove-climbers, and if planted close together they add to each other's charms. In the green-house one of the best climbers is *Rhodochiton volubile*, an awkward name for a most exquisite plant. At this season it festoons the rafters or pillars of a cool green-house with wreaths of purple, bell-like calyxes, with deep crimson almost black—corollas. It is of the simplest culture in large pots or when planted out in free soil.

One of your delightful Magnolias, *M. glauca*, or Swamp Laurel, has been in bloom for a month past, and the beauty of its ivory white cups and its delicious fragrance are a surprise to us. Our wet weather has apparently suited it, for I have never seen it so fine as it is this year. Usually the flower buds become scorched on dry soils before they have time to expand.

London, August 8th, 1888.

W. Goldring.

New or Little Known Plants.

Spiræa pubescens.

THIS dwarf *Spiræa* is a decided acquisition to gardens, flowering, as it does here, from the tenth to the fifteenth of May, or two or three weeks earlier than the well-known *S. triloba*, which it resembles in habit, although smaller in all its parts. Its flowers, as are those of that species, are produced in dense, umbellate corymbs from the ends of short, lateral, leafy branches of the year, and quite cover a considerable portion of the main stems. These are slender, terete, zigzag, slightly pendulous, two or three feet high, the shoots of the year densely covered with pubescents. The leaves are ovate-acute, sharply serrate above the middle or somewhat three-lobed, puberulous above and densely villous-pubescent on the under surface, especially on the midrib and two or three principal veins. The inflorescence, as pointed out by Maximowicz, is quite naked, with the exception of a line of hairs on the ventral sinus of the follicles. This plant must not be confounded with the *S. pubescens* of Lindley, which is referred by Maximowicz to *S. Chinensis*, which is considered by Mr. Hemsley the same as the *S. dasyantha* of Bunge, of which he remarks, "*S. pubescens* is certainly very closely allied, yet easily distinguished by its narrower, less distinctly veined leaves, having longer hairs on the under surface, and glabrous flowers."

*S. pubescens** is a native of the mountains of northern China and Mongolia. The plant from which our illustration on the opposite page was made, flowered in the Arnold Arboretum this year for the first time. It was raised from seed sent some years ago, by Dr. Bretschneider, from Pekin.

Cultural Department.

Cultivation of Native Ferns.—II.

SOME very delicate native Ferns which are difficult to cultivate do well grown in pots and wintered in a pit. In summer such potted Ferns may be sunk in a bed of coal ashes in a shady place. A frame for potted Ferns, alpine plants, etc., which has proved successful, is made as follows: A large shallow box, with loosely fitting bottom, is raised on logs about ten inches from the ground. Stones, broken crocks, etc., are laid on the bottom of the box to the depth of several inches, then covered with several inches of sand. The pots are sunk in the sand. This gives perfect drainage, which is a primal requisite, and no earth worms get into the pots on account of being raised from the ground.

In potting Ferns use plenty of broken crocks for drainage. The mixture of soil advised by Mr. John Robinson is peat, leaf mould from the woods, mason's sand and virgin loam, equal parts. He says cocoanut refuse may be used instead of leaf mould. The admixture should be light and porous, with no tendency to hold stagnant water. It should not be sifted. Charcoal broken in bits and crushed is a good thing to mix with soil for Ferns, as it tends to counteract any injurious results from excessive moisture.

Few of the Ferns we have to consider require pot-culture, and for more detail on this subject the reader may profitably consult Mr. Robinson's book on Ferns—referred to in the first article of this series.

It is often desirable to establish in pots choice Ferns which have been collected, before planting them in the open ground, especially if collected at a very unseasonable time.

* *Spiræa pubescens*, Turcz.; Bull. Soc. Nat. Mosc., v. 190. Maxim., Act. Hort. Petrop., vi. 93. Franchet, Pl. David, 106. Forbes & Hemsley, Enum. Pl. China, in Journ. Linn. Soc., xxii, 227.

Much pleasure may be derived from fine native Ferns potted and kept in the house for summer decoration. *Onoclea*, *Struthiopteris*, the *Osmundas*, large species of *Aspidium* and *Adiantum*, are particularly suitable for this purpose.

In cultural directions, a word should be said about rockeries. Rockeries, as commonly made, are unsatisfactory. They are too apt to be made of rocks with a little soil, whereas they should be large bodies of soil, with rocks buried and cropping out on the surface. Rockeries are frequently built to a considerable height above the surface of the adjacent soil; in fact, much too high, as they then require excessive watering to prevent their drying up. For a small rockery of four to eight feet in width twelve to eighteen inches, or, at most, two feet, is quite high enough for the highest parts. That is quite sufficient to give the varying elevations desirable for different kinds of Ferns and to give a pleasing effect.

All of the Ferns considered, except those specially noted, can be grown perfectly well without rocks, and in so far they may be considered superfluous. In my garden there is no rockery, properly so called. Stones and rocks of considerable size, however, may be laid on the ground and half buried in Fern-beds, giving a good effect and helping materially to retain moisture by covering the soil.

The moist, cool surface of rocks makes a grateful surface along which the roots of Ferns, and other plants as well, like to creep. At the Botanic Gardens in Cambridge, some delicate species, such as *Asplenium viride*, *Pellaea gracilis*, etc., are grown very successfully in niches of rock-work, with very little soil, although plentifully supplied with moisture, and covered with sashes in winter.

Rocks may be used with great advantage and moderate cost on a natural bank or steep incline, and in such places are most admirable.

Directions for making rock-works are to be found in Robinson's "Alpine Flowers."*

It is to be understood that we are considering rockeries for growing Ferns and for small garden effects, not rockeries of sufficient dignity to give landscape effects; for these special studies are required.

The propagation of Ferns of the class under consideration is generally an unimportant affair, as they are, for the most part, comparatively easily obtained from the woods. They may be propagated by dividing the crowns or running root-stocks during the dormant season, in autumn or early spring. They can also be propagated from spores. For directions for this last method, see Mr. Robinson's book. Ferns are seldom much troubled by insect pests. *Onoclea sensibilis* is the only Fern which attracts insects to any extent. Garden slugs sometimes do damage to the smaller species.

Ferns may be purchased from a few collectors and dealers in this country, but by far the most interesting way, if possible, is to collect them one's self. It vastly increases the pleasure to be derived from the Fern garden to have each specimen a pleasant reminder of the woods, mountain, valley or swamp where it was collected. Seek out some rich locality for Ferns, and with a beginning thus made, a good collection may soon be built up. Fortunately, some of the most desirable species for cultivation are also the commonest.

Ferns are best transplanted in the dormant season, but they may be moved successfully at any time of year. For the beginner early autumn is a good time to collect, as the dormant season is approaching, and yet the various species are easily recognized, as the fronds have not yet dried off.

It is not necessary to consider the season in collecting Ferns, for they can be transplanted at any time with scarcely the loss of a single plant. Success in transplanting most native Ferns is so certain as to be a foregone conclusion, if reasonable care is given them.

When collecting get up all the roots possible and pack in slightly moistened sphagnum moss for transportation. In default of sphagnum, any moss, fern fronds, leaves or grass will do, if the journey is not a long one. Excessive moisture is objectionable in packing, as it induces the Ferns to throw out a weak, sickly growth. The fronds may be cut off without permanent injury, if it is necessary to save space in packing, although it is best to leave them on, especially with ever-green species.

To show the extreme hardiness and vitality of Ferns, it may be mentioned that some years ago, in midsummer, several species of Ferns were collected far from home. The tops were cut off, the roots wrapped in moss, and for eight weeks they were carried in a hand-bag, without the loss of a single specimen. Again, in Covent Garden Market, London, dry roots of Ferns are exposed for sale and grow perfectly

* "Alpine Flowers for English Gardens," by W. Robinson, F.L.S. London, 1879.

well, notwithstanding the fact that they are quite dry and have few or no roots when sold.

In digging up Ferns a stout trowel is good, a dull, stout, broad-bladed knife is better, and best is a tool sold in London shops, but easily made by any metal worker. It is a gouge-shaped piece of steel riveted firmly to a hard wood handle; the tool is eleven inches long and one and one-half inches broad. It is invaluable in collecting wild plants, as it is strong and narrow, so that it is easily inserted into crevices; it is half knife, half trowel. A sharp spade and a hatchet or strong knife are of value in collecting roots of some large Ferns.

Boston.

Robert T. Jackson.

Early Apples.

ABOUT thirty years ago I purchased a number of trees of the leading kinds of Apples in order to study their qualities and their adaptability to my soil.

Although a tart fruit, and one which may with propriety be called a Sour Harvest Apple, it will not compare in size or quality with the apple generally known by that name in this state, which is the Primate. This, in perfection, is unquestionably the best early apple we have. Its season is in July and August, and it lasts four or five weeks. Its defects are extreme liability to insect attacks and its tendency to become watery. Its crisp, tender flesh and fine flavor, added to its earliness, render it a great favorite in spite of the above objections. If there are locations where it is exempt from these drawbacks it cannot fail to satisfy the most fastidious. It is also an early and regular bearer.

The Red June is a very handsome fruit, and the tree a fine, erect grower, but the apple lacks the tender crispness of the others, and is subject to the apple-scab, which sometimes mars a great portion of its surface. This year, however, they were finer and more beautiful than ever. The Duchess of Oldenburg is a large, fine-looking fruit, a little later than any of

Fig. 52.—*Spiraea pubescens*.—See page 330.

Among the early kinds planted there were Red Astrachan, Early Harvest, Early Joe, Summer Rose, Keswick's Codlin, Duchess of Oldenburg, Carolina Red June, Primate and Saint Lawrence. These trees are all alive to-day, and a failure to get Apples every season from some of them has never occurred. Of the above named, the Codlin is the least desirable, though a prolific biennial bearer. The fruit is too acid and low in quality either for dessert or for cooking. Astrachan is also quite sour, but a far better Apple to eat than the Codlin—earlier, handsomer and better in every way. Its chief demerits are its liability to rot early, and its habit of growing in clusters, which affords a fine nesting place for the codling moth and other insects. If they could be thinned till single Apples took the place of clusters, it would no doubt obviate this difficulty to a great extent, and, perhaps, when spraying the trees with arsenites becomes general, we shall have less to fear from these insects. Early Harvest comes in at the same time, and though less acid, is smaller, and not so liable to insect depredations.

the preceding, and though not so desirable as a dessert fruit, is an admirable Apple to follow these for cooking purposes. It generally grows very smooth, much more so than Astrachan, Codlin or Primate. It ought to be a good market fruit, owing to its fine size and attractive appearance. The Primate is too tender in this respect, and needs to be handled more carefully than eggs; the least pressure mars the delicate skin and injures its appearance.

The Saint Lawrence is in season at the same time as the Oldenburg, and is a better Apple, being crisper, milder and more highly flavored. The flesh is white and tender, often streaked or veined with red. Its season is in August, just after Summer Rose is ripe. It is an abundant biennial bearer. The only objection I have ever found against it is that it does not last long enough.

Early Joe proved to be Summer Rose, a small to medium sized Apple of fine quality and handsome appearance, the largest specimen reaching a diameter of two to two and a

half inches. They are remarkably handsome, always sound, smooth and fair; indeed, a wormy one is hard to find and blemishes of any kind are rare. What peculiar properties the tree possesses, why it should escape insect attacks and always present the same smooth and wax-like appearance in the midst of other varieties badly affected, is another unsolved problem. This fact, together with its other good qualities, increases my appreciation of it every year, so that, all things considered, it commends itself as the best Apple of its season that I have grown. The smallest specimens of an inch in diameter are as perfect as the larger ones, which is not true of any other Apple with which I am acquainted.

Since writing the above the report of the United States Department of Agriculture has come to hand, in which the chief of the Pomological Division has this to say of the Summer Rose: "In my opinion this little favorite surpasses Carolina June, Early Harvest, and all other early Apples. It is as early as any, begins to bear soon after planting, and seldom fails to carry a full crop, even when most varieties fail. The tree has a beautiful, round head, the branches are stout but not heavy, with very distinct gray dots upon the new growth. It is essentially a family Apple, beginning to ripen with the very earliest, and continuing for about six weeks. It sells well in market, but is more especially a dessert variety. It originated in New Jersey. Size: small, two to three inches; shape: flat to round, regular; surface: very smooth; color: white, with stripes and splashes of the most delicate tints of carmine; dots, very small; basin, wide, abrupt and rather deep, regular; eye, small and colored; cavity, narrow, regular, not russeted; stem, usually quite short; core, large, closed, regular, meeting the eye; seeds, numerous, short and plump, light brown; flesh, white, with rarely a tint of pink next the skin; fine-grained, tender, crisp, juicy, except when over ripe; flavor, sub-acid, very pleasant; quality, as good as the best of the early kinds; season, June to August, in the Central States."

In conclusion, let me call attention to the unusual prevalence this season, among the early apples, of that insidious enemy, the apple maggot. The Jersey Sweet has been unfit for anything but stock food for years past from the presence of these insects, and Golden Sweets have been nearly as bad. This season Primate, Astrachan and Early Harvest have been affected. The increase of this pest gives abundant cause for alarm, and measures must be sought for checking its progress, or our early apples are doomed.

Montclair, N. J.

E. Williams.

Hyacinths for Forcing.

SELECTIONS should be made and bulbs secured as soon as possible; the sooner ordered the better the stock will probably be, and the prices are not likely to be lower. Besides, one of the chief points to observe in forcing Hyacinths is to have them potted early, so as to give them a long season to fill the pots full of roots before winter sets in. Well-rooted Hyacinths usually throw up perfectly developed, strong flower spikes; poorly-rooted bulbs produce malformed spikes or often fail altogether; indeed, no poorly-rooted Hyacinth is fit for early forcing. Many growers pot Hyacinths for succession, say, a lot about the first of September, and others at intervals of three or four weeks till the end of October, but this plan has no advantages. Some varieties naturally flower earlier than others, and, with a judicious selection of varieties when forcing time comes, and by introducing the earliest kinds first to the forcing-house, a continuous supply can be maintained from the first of February till April.

The deep Hyacinth pots are the best, but ordinary flower pots are good enough. One bulb in a five-inch pot, or two or three bulbs in a six-inch pot are sufficient. In this way Hyacinths can be used to advantage as pot plants in the window or green-house. But florists who grow Hyacinths for cut flowers only, seldom pot them at all, but grow them in flats, three to four inches deep, and of any convenient size. The bulbs are set one or two inches apart.

Any fresh, fibrous, loamy soil, such as is used for pot-plants, will answer for Hyacinths, but a little extra sand helps it. Rotted sods, with one-fourth its bulk of well-rotted cow or barn-yard manure or leaf soil and one-fourth of sharp pit or river sand, is a capital compost. Be cautious about using much manure in the soil; rather apply stimulants from the surface after the bulbs are started in the forcing-house. And never use fresh, wet or pasty manure.

All bulbs will grow and bloom well if in potting they are buried in the soil, as is the practice with Freesias, Alliums

and Crocuses, and nearly all of them will flourish as well if the bulbs are partly above ground, as Cyclamens and Hyacinths are usually grown. In potting, place the Hyacinth bulbs two-thirds their depth in the soil, and throw a dash of clean sand under and about them to induce ready rooting and lessen any tendency to decay.

After potting them water from above through a fine rose and place them close together in some cool place (but not under trees) out of doors, bank them over with four or five inches of earth, sand or ashes, and let them stay there till November, when they may be taken indoors to a cool part of the cellar or shed, and there again covered with earth, coconut fibre, half decayed leaves, or other material, but the covering now need not be so deep as it was out of doors. Never allow frost to reach the bulbs; at the same time keep the temperature of the place where they are stored below 45°.

By the first of January some of the bulbs will begin to grow a little. A few of the most advanced may then be brought into the green-house, and kept for the first eight or ten days in a shady place and in a temperature of 45° to 50°. After that time remove to a warmer temperature, say 60° to 65°. But until growth advances pretty well, do not place them in a light, sunny place; it is a good plan to invert a flower pot over newly exposed crowns for a week or more, till the foliage and flower spike grow up a little and assume a greener color. High, collar-like bands of stiff paper or tin are used for the same purpose. After the Hyacinths come into bloom it is well to remove them to a moderately cool room or green-house, say 45° to 50°, in order to stiffen the stems and prolong the duration of the flowers.

Catalogues are filled with varieties of Hyacinths, and it often is hard to choose the most serviceable sorts. Those mentioned in the annexed list are all excellent and well-tried varieties for cultivation in pots. The double varieties are not as desirable as the single ones, and there are not many good yellow varieties.

SINGLE-FLOWERED HYACINTHS.—White.—Alba maxima, Baron Van Thuyl, La Grandesse.

White, with rose shade.—Grandeur à Merveille.

Light red.—Charles Dickens, Fabiola, Lord Macaulay, Mrs. Beecher Stowe.

Dark red.—Amy, Garibaldi, Pelissier, Von Schiller.

Blue.—Charles Dickens, Czar Peter, Leonidas, Lord Derby.

Dark blue.—General Havelock, King of the Blues, Sir Henry Barkley, William the First.

Yellow.—Ida, Bird of Paradise, Obelisk.

DOUBLE-FLOWERED HYACINTHS.—White.—Florence Nightingale, La Tour d'Auvergne, Prince of Waterloo.

Rose.—Grootvoorst, Lord Wellington.

Dark red.—Louis Napoleon, Sans Souci, Waterloo.

Light blue.—Blocksburg, Rembrandt, Lord Nelson.

Dark blue.—Garrick, Laurens Koster, Louis Phillippe.

Yellow.—Goethe, Jaune Supreme. *William Falconer.*
Glen Cove, N. Y.

Notes from the Arnold Arboretum.

Tilia dasystyla (*T. euchlora* of C. Koch, a name which he thought more appropriate than the much older one of *dasystyla*), is certainly, in foliage at least, the handsomest of all the Lindens. The ample leaves are thick and somewhat leathery, dark, deep green and beautifully shining on the upper surface, while the lower surface is paler green, with rather small tufts of light brown hairs in the axils of the veins. The young branches are conspicuous from the bright green of the bark which covers them. This tree is a native, probably, of the mountains of Asiatic Turkey and of the Caucasus. It is not very often seen in cultivation, although of late years it has been somewhat planted in Berlin and other German cities, and it is occasionally met with in English nurseries. Here the plants, although still young, are perfectly hardy; they have not flowered yet, and, of course, give no idea of the habit this tree will assume here, or of its probable value in American plantations. Has any one else planted this tree in the United States? If so he will confer a favor upon the Editor of this journal by communicating to him the results of his experiences with it.

The Sorrel Tree, or Sour-wood (*Oxydendrum arboreum*), sometimes called also the Lily-of-the-Valley tree, on account of the shape and color of its flowers, is now blooming. It is the *Andromeda arborea* (the first name) of some of the old collections. The Sour-wood is hardly more than a tall shrub at the north, here rarely attaining a height of more than ten or twelve feet, but in the south, in the mountain forests of Carolina and Tennessee, where it grows in its greatest perfection,

it becomes a slender tree, often fifty feet high. It has deciduous, membranaceous, lanceolate leaves, four to six inches long, and an inflorescence consisting of a spreading panicle of one-sided, drooping, many-flowered racemes, terminating the leafy branches of the season. The pure white, bell-shaped flowers are a quarter of an inch long. It is surprising that this beautiful plant is now so rarely found in gardens. Its handsome, white flowers open at a season when few trees are in bloom, while the brilliant colors, unsurpassed, perhaps, by those of any other American plant, which its leaves take on in autumn, make its cultivation doubly desirable. The name *Oxydendrum* is derived from two Greek words, signifying sour and tree, and relate to the acid flavor of the leaves.

Another plant peculiar to the mountain forests of the Southern States, and too seldom seen in gardens, *Clethra acuminata*, is now in bloom. It is a tall shrub, sometimes eighteen or twenty feet high in the high southern valleys, but at the north rarely attaining half that size. It has large leaves, four to seven inches long, and nodding, solitary racemes of yellow-white flowers, shorter than the caducous bracts. This plant is perfectly hardy here. It is less beautiful, however, than the northern representatives of this genus, the familiar Sweet Pepperbush, which just now is the chief ornament of northern swamps, which it enlivens with its lustrous, dark green foliage and handsome, upright racemes of pure white, spicily-fragrant flowers. This is one of the handsomest shrubs found in North America; it is easily cultivated, and thrives in any good garden soil. Some attention, of late years, has been directed to the value of the *Clethra* as a garden plant, and it is now found occasionally in commercial nurseries.

Callicarpa purpurea, a member of the Verbenaceae family, is now in flower. It is a shrub three or four feet high, with erect and rather rigid branches, opposite, ovate-acuminate leaves, and axillary cymes of small, inconspicuous purple flowers, which would hardly entitle this plant to a place in the garden. The inconspicuous flowers, however, are followed in the autumn by numerous bright purple glossy fruit which quite cover the branches, making this plant and the other species of the genus exceedingly beautiful and attractive objects. *Callicarpa purpurea* is a widely distributed plant from Japan to India, and is practically hardy here. The stems are sometimes killed back in severe winters nearly to the ground, but they always spring up again in time to produce the late flowers which do not appear until the early weeks of August. There is an American species of this genus (*C. Americana*) found from Virginia to the Keys of Southern Florida, generally near the coast, Texas and the West Indies, which unfortunately is not hardy at the north, as it is in fruit a more showy plant even than its Asiatic congener. *Callicarpa* is derived from two Greek words, meaning beautiful and fruit; and these plants are sometimes called French Mulberries, for no very apparent reason. The Japanese species is easily cultivated, requiring no special soil or treatment; and it can be easily raised from seed, which are produced in abundance and germinate freely.

Rosa Beggeriana, var. *genuina*, is a wild Rose of central Asia which has the merit of keeping in bloom here all summer long. Its introduction into cultivation is due to Dr. Aitchison, botanist of the late Afghan Boundary Survey who found it "a common shrub at the western extremity of the Kuram district and throughout the Hariab, in vicinity of streams and water courses; it is also very common near cultivation, where it forms natural hedges along the various channels of irrigation, at an altitude of from 4,000 to 9,000 feet. It forms a bush of from four to six feet in height, the latter in more favored localities. When in bloom it is covered with a mass of pure white small flowers. The fruit is little larger than an ordinary pea, at first orange-red, when fully ripe of a deep purple-black. The shrub is briar-scented. This species is employed, as well as *R. Eglanteria* and *R. Eca*, the Gooseberry, and Hippophae, in forming hedges in the Hariab district; and is much browsed by cattle, especially goats."*

This Afghan Rose forms here a stout, tall bush, five or six feet high, with slender and rather flexible branches, without prickles, and sparingly armed with slender, slightly recurved spines. The leaves, which are composed of three or four pairs of small, oval, sharply serrate leaflets, are pale gray-green. The hardness of this plant and its habit of blooming continuously throughout the season, make it a useful, as well as an interesting, addition to single Roses.

There is no genus of plants hardy here which contains so many shrubs, with handsome flowers appearing in August, as *Hypericum* or St. John's Wort. There are a number of Ameri-

can species in flower in the collection now; but as drawings of several of these have been made, and will be published in future issues of GARDEN AND FOREST, they need not be named even at this time. A few foreign species, however, are worthy of mention. The handsomest of these is *H. calycinum*, a native of south-eastern Europe, and popularly known as Aaron's Beard or the Rose of Sharon. It is a dwarf plant, spreading rapidly by creeping, woody root-stalks, with simple stems, barely a foot high, and large, crowded, ovate or oblong, obtuse, dark green leaves, covered with small pellucid dots. The flowers are bright yellow, three or four inches in diameter, two or three together, upon the summits of the branches, or sometimes in corymbs of five or six. In England this plant is often used to cover the ground in shrubbery beds, for which purpose its compact habit, almost evergreen foliage, and power to spread rapidly, admirably adapt it. But, unfortunately, here it is not entirely hardy; and the stems, in spite of winter protection, are often killed back to the ground. The roots, however, survive the most severe winters, and the annual killing back, while it prevents the plants from spreading and so largely destroys their usefulness for clothing wide stretches of naked ground, does not prevent them from blooming every year, or destroy their beauty for the herbaceous border or the margin of the shrubbery. The only Japanese shrubby species of *Hypericum* is *H. patulum* (*H. Euralum* of some collections). It is a hardy plant here, with slender, smooth, spreading purple branches, not more than two feet high, ovate-acute, entire, revolute leaves, and usually solitary, pale yellow, somewhat cup-shaped flowers. Although less showy than some of the American species, *H. patulum* is one of the most delicate and graceful of all the *Hypericums*, and one of the best of summer-blooming shrubs for the rock-garden.

Androsæmum hircinum (*Hypericum hircinum*), the Goat-scented St. John's Wort, is a very showy plant in flower, with erect stems, two or three feet high, winged branches, ovate-lanceolate leaves, somewhat emarginate at the base, their margins glandular, and very large, pale flowers, with narrowly acuminate petals and long styles. The strong and disagreeable odor of the flowers, to which this plant owes its common name, makes this species, in spite of their profusion and individual beauty, less attractive than many of the other St. John's Worts. There is in the collection a dwarf variety (var. *minor*), a compact and handsome little plant identical with the species, except that it is smaller in all its parts. *Androsæmum hircinum* is a native of southern Europe from northern Spain to the Grecian Islands, and, in spite of its southern origin, is perfectly hardy here.

August 13th.

J.

The Forest.

The Care of Woodlands.

To the Editor of GARDEN AND FOREST:

Sir.—I read a great deal of the importance of planting forest trees and of maintaining forests, but I can find no definite instruction for the care of woodlands. I have two hundred acres of fine wood, but it yields me nothing. How is this property to be made increasingly productive? Can you give me some practical advice or tell me where I can find it?

Baltimore, Md.

Stewart Brown.

[No question is more often asked the editors of this journal than how natural woods should be treated in order to make them yield the greatest profit. It is, of course, impossible to do more than explain a few of the general rules which can be universally applied in the management of woods, with the understanding that each particular piece of woodland or forest requires special study and special treatment, dependent upon its character and condition, the nature of the soil upon which it stands, and the crop which it is desired to obtain from it. A forest of deciduous trees—especially in this country, where a large number of different species are almost universally associated together—is more difficult to manage than one composed of Conifers, which usually grow gregariously, and are, moreover, little dependent upon artificial thinning and pruning. The operations of scientific forestry are all directed to the perpetuation of the forest. They are based on the principle that trees can be grown on certain land more profitably than any other crop, and that this fact being established, rural economy demands that the forest should be a permanent fixture on such land.

*Aitchison, Jour. Linn. Soc., xix, 161.

The operations of thinning, cutting, planting and sowing are all directed to securing the natural reproductions of the forest with the least possible expenditure of money, to which the element of time is properly considered subordinate. There are, of course, exceptions to this rule, as in the case of a forest of Conifers growing upon a level sandy plain, when it is often more economical to cut down all the trees, grub up the roots, and replant, than to allow the forest to reproduce itself naturally by means of self-sown seeds.

The deciduous forests or bodies of woods now found in the more thickly settled portions of the Eastern and Northern States, and generally connected with farms, are usually of two classes: (1) Woods composed almost entirely of old trees, belonging to species of comparatively little economic value, the trees valuable for timber or for fuel having been cut from time to time when needed on the farm or to bring in a little money. The excessive pasturage to which all such woodland is subjected has prevented the growth of young trees to replace those which have been cut, and has destroyed the undergrowth which protects seedling trees, checks evaporation from the surface, where the forest-floor is not densely shaded, and by preventing the blowing away of the fallen leaves, helps to increase its coating of vegetable mould. Such woods, when they are not injured by excessive pasturage, often suffer by the rooting of hogs, which destroy many young trees, and, by selecting the sweet seeds of the White Oaks, the Chestnut and the Beech, and discarding the bitter acorns of the Black Oaks, are, in some parts of the country, gradually changing the composition of deciduous forests. The trees which remain in these old woods often show, in dead branches and dying tops, the effects of injudicious thinning, and of the exhaustion which excessive pasturage brings, sooner or later, to every forest.

(2) Coppice-woods—that is, woods composed largely of suckers, or the growth from the stumps of trees previously cut, it being the custom in some parts of the country, especially in New England, to cut a piece of woods clean, leaving the old stumps to furnish a fresh supply of trees. The disadvantages of this system are, that stump-shoots never make as long-lived or valuable trees as seedlings; that as each old stump produces several shoots, these are crowded together so that no one of them is able to grow into a good tree; that some species of trees produce shoots from the stump more freely and more vigorously than others, so that if left to themselves, these species must eventually occupy the ground, to the exclusion of all others, and that, as a stump loses its power to produce shoots, after two or three crops have been taken from it, a wood treated continually in this way must either disappear eventually or change the character of its composition. Animals are not less injurious to the coppice than to the wood in which old trees have been left standing; they devour and break down the young shoots or root them out entirely.

The first thing to be done, if a piece of deciduous woods, whatever its character, condition or extent, is to be improved and made permanently profitable, is to exclude from it rigorously all browsing animals. Then the owner must decide what sort of trees he desires his woods to be composed of principally. The nature of the soil and the character of the native vegetation should primarily determine his choice, which may depend secondarily, however, upon the purposes to which his forest-crop is to be applied, and upon probable future local demands for timber. In European countries, where the number of species of trees growing naturally is very small, the scientific forester is rarely compelled to occupy himself with forests composed of more than two different deciduous trees, the Oak and the Beech, but in American forests, where sometimes twenty or thirty species of more or less valuable trees are closely associated together in small areas, the difficulties of forest management are greatly increased, and we have still to learn how a mixed forest of many species can be most profitably

worked. At present, at least, the owner must select the most valuable species among those which grow the most freely on his ground, and then, the crop being thus decided upon, devote himself to the development and the succession of the individuals of those species. The nature of the crop being thus determined upon, all the trees, in the case of woods of the class first described, not belonging to any of the species which are to be perpetuated and which have passed their prime and therefore cannot be profitably left standing, should be cut. The condition of a tree can be roughly decided by an examination of its top; when the upper branches begin to fail, it is a sign that it is no longer in a healthy condition or capable of producing much more material. A tree in scientific forestry is considered ripe and ready for the axe when the bulk of its annual increase of wood diminishes or does not increase. This information is easily obtained by means of a simple mechanical contrivance which enables the forester to measure the exact thickness of the annual deposits of wood without injury to the tree and so to determine accurately the annual increase of material. If old individuals belonging to the species to be perpetuated in the forest exist, they should be left to bear seed, from which the future forest is to spring; and the condition of these old trees can often be greatly improved and their lives considerably prolonged, by cutting away all dead branches, by shortening the others, and by reducing the heads. This process not only increases the vigor of the individual, but allows the light to penetrate to the forest-floor about it, and so enables the seed which falls to germinate and grow. Young trees, if any exist of the species selected, must from time to time be freed from the encroachment of undesirable neighbors, and the seedlings, which will soon appear after animals are excluded from the forest and light is admitted by the removal of decrepit or useless trees, must be thinned every few years. Gradually, as the young trees grow up, the remnants of the old forest may be removed—first, the unpruned trees of the non-selected species, not cut when the improvement was undertaken, and then finally, and after the ground is sufficiently stocked with seedlings, the old seed-bearing trees of the selected sorts. The management of a coppice, with the exceptions that there are no old trees to remove, and that the ground is already stocked with a growth of shoots all of the same age, is practically the same. The variety of trees of which the woods is to be composed being determined upon, their growth must be encouraged, and the others removed. When several shoots proceed from a single stem only one should be left to grow, unless it is found that a particular forest can more profitably produce posts or railroad ties than timber of larger dimensions, in which case better returns are often obtained by allowing several stems to grow up together. A mixed system is often found the most profitable in the treatment of a wood originally coppice. A certain number of trees are, at the outset, selected to grow to maturity. All the rest of the shoots are then cut away to allow these selected trees to grow without interference, and thus to get a good start. The next crop of stump-shoots grow up, preventing the growth of side branches on the standard trees, but without interfering otherwise with their development, and serving as an undergrowth and protection to the forest floor. The old stumps, after two or three crops of coppice-wood have been taken, cease to be productive, and the ground which they filled, unless it is too shaded by the standard trees, is finally occupied with a growth of seedlings.

There should be in a perfectly healthy and satisfactory forest three stories of vegetation, so to speak. 1st. A growth of tall trees, near enough together to insure the development of tall, straight stems, without low side branches, which destroy their value for timber; but not so near that their heads exclude all light from the forest floor, and so prevent the growth among them of other plants; 2d. A crop of younger trees growing under and among the last, either of the same species or of some valuable species

capable of supporting shade, and which will replace the older trees when these reach maturity; and 3d, a growth of low undershrubs and seedling trees covering the forest floor, holding the leaves which fall from above, and containing the material for future forests. The task of converting the most neglected and unpromising piece of woods into a forest of this character is not difficult in this climate. It requires only a short time comparatively, but it cannot be done without labor, and without careful study of trees, their nature and requirements.—Ed.]

Correspondence.

To the Editor of GARDEN AND FOREST :

Sir.—The admirable words which have appeared in GARDEN AND FOREST upon the gardener's art have given birth to these thoughts which, perhaps, are worth a place in your columns :

The right of landscape gardening to be acknowledged as one of the fine arts, will not be denied by those who have taken time and pains to consider what is comprehended in those two words.

The first and vital element of success in landscape gardening, lies in the character and intelligence of him who undertakes it. There must be in him an intense, innate love of nature which cannot be repressed—a love which delights in all her beauties, which would bind up all her wounds, and which sympathizes in all her varying moods. It is a reality, and by a strange instinct nature recognizes the fact and adorns herself for the true hearted.

Successful floriculture and arboriculture demand an affection as genuine and self-denying in character as the culture of a little family in the home nest. Care, watchfulness, tenderness, are the elements of success, and in both cases the lack of them is not only painfully obvious, but a sure cause of failure. We are close akin to the fauna and flora of earth.

There is an idiosyncrasy peculiar to the creation of landscapes. The painter, the sculptor and the architect all deal with dead materials. Every touch of the brush, every stroke of the chisel, will produce effects which will remain until age disintegrates or untoward circumstances destroy them. The landscape gardener deals with living materials, he is *en rapport* with them, there is a mutual affinity, and if the artist proves faithful to his trust, he will achieve a living picture. His designs are planted, not painted, and it may be they will not reach their perfection for fifty years or more. They are designs which prefigure the future, and are unique prophecies.

We must also consider the breadth and extent of his work. A skilled painter may require years to perfect a painting of extraordinary size. What then shall we say of a stretch of canvas (so to speak) of hundreds of acres, every foot of which must be covered with the embodied thoughts, conceptions and imaginations of the artist? Unfortunately for him, a park, especially in cities or in their immediate suburbs, can rarely be chosen for original beauty of situation, or facility of adaptation to his plans. But there is a worse living hindrance—park commissioners and politicians who insert themselves between himself and his designs like gravel between cog-wheels.

His whole work must be conceived in accordance with the laws of nature, and developed in the most perfect and enticing forms. In his creation no unsightly shadow of ugliness will be tolerated by way of contrast or relief. Contrasts indeed there must be, but such only as come from differing forms of beauty. Delicacy and grace are heightened by boldness and ruggedness.

There is another consideration which adds to the complexity of the work of a landscape gardener. No duplication, however attractive the original device may be, is allowable. No groups of trees or rocks, no lake or dell, can "have its brother," save in their natural relation to each other. The broad highways for carriages, the bridle paths and the foot paths, must be all kept severely separated, as the glimpse of a neighboring walk would be an unpermitted suggestion of limitation.

All these paths must abound with points of beauty—distant views through long vistas, distant views suddenly revealed, groves whose rich, thick foliage forms a leafy screen, indicate paths, cunning snuggeries and "delectable bowers" which those dear ones seek who are all in all to each other—and not the least beautiful, the wondrous effect of light and shadow on rock and fen, on flower and shrub, on lawn and coppice.

But this same landscape gardener is also an architect, a "*pontifex maximus*," not in the magnitude, but in the number of his bridges and in the variety and appropriateness of his plans. All this wealth of beauty and comeliness is to be created—born out of the fullness and richness of the imagination.

It is a work which none but a true artist could possibly design and achieve.

C. Allen.

Providence, R. I.

To the Editor of GARDEN AND FOREST :

Sir.—I have read the two articles on Prospect Park with interest. Their value is impaired by the fact that they seem to be based upon information obtained from the report of last January, or prior to that date. Since January the Commission has been reorganized, and the criticisms upon its spirit and purposes were not pertinent at the time of the publication of the two articles.

Alfred C. Chapin.

Mayor's Office, Brooklyn, August 1st, 1888.

[The criticisms to which Mayor Chapin alludes were directed to the ignorance and indifference which are responsible for the deplorable mismanagement of Prospect Park as indicated by the twenty-seventh report of the Brooklyn Park Department. Since the publication of that report the Park Commission has been reconstructed, as the Mayor states, and as suggestive of the spirit and purposes with which the members of the new Board will endeavor to discharge the important duties entrusted to them, the Mayor's letter will be read with extreme gratification.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—Although Washington Square is partially encircled by fine residences, it is seldom crossed by their occupants, and, forming the boundary line between up-town and down-town streets, is frequented almost solely by what are called the "lower classes." Indeed, one part of it is popularly known as the "Tramps' Retreat." But do these facts supply any reason why the park should be neglected by the authorities and present a very different aspect from either Union or Madison Square? If it is frequented chiefly by the poor, and, therefore, by large numbers of persons to whom it offers their only chance for refreshment and the enjoyment of any approach to natural beauty, should not particular care, instead of a conspicuous want of care, be its portion?

A Down-town New Yorker.

Recent Publications.

Historie des Plantes, par H. Baillon, Paris, Librairie Hachette & Co. The ninth volume of this classical work has appeared. It is devoted to a study of *Aristolochiaceæ*, *Cactaceæ*, *Mesembryanthemaceæ*, *Portulacæ*, *Caryophyllaceæ*, *Chenopodiaceæ*, *Eleatinaceæ*, *Frankeniaceæ*, *Droseraceæ*, *Tamariaceæ*, *Salicaceæ*, *Batidaceæ*, *Podostomaceæ*, *Plantaginaceæ*, *Solanaceæ*, and *Scrophulariaceæ*. This volume, like its predecessors, is illustrated with beautifully executed wood-cuts, quite equal to any of the same character that have appeared in recent French botanical works. Higher praise cannot be given to them.

Number 155 of the *Journal of the Linnean Society* (vol. xxiii.) is devoted to a continuation of Forbes and Hemsley's useful catalogue of Chinese plants, prepared in the herbarium of the Royal Gardens at Kew, and which is now brought down to Compositæ. Great interest is attached to this catalogue, because it contains the new plants recently discovered by Henry and other Englishmen in the central, mountain region above the great cataract of the Yangtse, or about 1,500 miles from the coast. This region, which until recently has been quite unknown, botanically, proves to be extraordinarily rich in new genera and species, and with the Yun-nan district to the south-west of it, of whose richness the Abbé Delavey has already given us a good idea, is now the best field for botanical exploration. It may be expected, too, to furnish a large number of hardy and interesting plants, especially trees and shrubs, to European and American gardens, as the climate, judged by the latitude and elevation of this region, is probably not very unlike, although somewhat less humid than that of the high Alleghany Mountain region of our Southern States. Mr. Hemsley describes, in the present issue of the catalogue, seven new species of *Viburnums*, of which one is said to attain a height of thirty feet, and a new tree with the

flowers of a *Viburnum*, but with digitally compound leaves, for which a new genus, *Actinotinus*, is proposed (Hook, Ic. pl. xviii, t. 1740). No less than six new species of *Lonicera* are described, of which one at least, *L. fuchsoides* (t. 9), recalling in general aspect some of the Andean species of *Fuchsia*, should prove a real addition to garden shrubs.

There are interesting additions, too, to *Rubiaceæ* and *Valerianaceæ*, although proportionately less numerous than those already mentioned, and of much less horticultural interest. The publication of this catalogue cannot fail to stimulate the study of botany and the collection of plants by European and American residents in China, where, with the single exception of central Africa, there is now certainly more to learn about plants than in any other part of the world.

Notes.

Petunias and Drummond's Phlox are used largely in bedding at New England sea-side resorts. Both of these plants seem to flourish in the salt air.

M. Naudin finds that *Eucalyptus coccifera*, *E. anigera* and *E. cordata* are the hardiest of the great collection of *Eucalyptus* tested by him in the gardens of the Villa Thuret.

It is said that Mr. Gladstone owns a large tract of land on the Canada shore, commanding a fine view of Niagara Falls, which he refused to sell when the Canadian Reservation was formed.

It is stated in *Nature* that one of the largest Pine trees (*P. sylvestris*) ever grown in Sweden has recently been cut. It measured over 120 feet in height, and was 12.5 feet in diameter two feet from the ground.

The fact that the dried fruit product of California has increased from 5,070,000 pounds in 1883 to 26,605,000 pounds in 1887, gives some idea of the marvelous development of the fruit-growing industry of the State.

The Wisconsin State Horticultural Society offers liberal premiums for seedling Apples which will endure the trying climate of that region, and energetic search for chance seedlings that may be hardy is being made, with efforts to learn their history.

Hieracium aurantiacum, the European species, which has proved a troublesome weed to farmers in some parts of this State, especially in the neighborhood of Albany, has now appeared in Marion, on the shores of Buzzard's Bay, in Massachusetts.

A correspondent, writing to an English horticultural journal, describes a specimen of *Hydrangea hortensis* that he saw at a flower-show at Chichester. It was growing in a twelve-inch pot, and bore 100 heads of bloom, many of them as large as those commonly seen on single-stemmed market plants.

From the last annual report of Sir R. Schomburgk, director of the Botanic Garden at Adelaide, in South Australia, just received, it appears that the so-called Japan Clover (*Lespedeza striata*), now such an important and valuable forage crop in our south Atlantic States, does not promise to be valuable in south Australia, where the climate, doubtless, as it is in the Mediterranean Basin, is too dry for it.

The discovery of two new enemies of the Asparagus beetle is announced in the *Annales de la Société Entomologique de France*—one of them an internal parasite, which doubtless has had an important influence in controlling the numbers of the beetle. In making a note of this in *Insect Life*, the editors say that up to the present time not a single natural enemy of this insect has been discovered in America, although the beetle is doing much damage and extending its work over a larger area every year. The obvious suggestion is made to import this parasite from France and give it a chance to prey upon the beetles.

As one might expect, a poet who loves nature, often, in a word or two, depicts the character of a tree or flower more effectively than do pages of commonplace description. For example, in speaking somewhere of the Larch, Wordsworth notes the beauty of its vivid light green in early summer and then remarks upon the contrast this offers to that "death-like character in winter" which is so peculiarly its own. Certainly if we were to choose from the vegetable world an image not of deadness merely but of death itself, no tree would be so appropriate as the Larch. But it took a poet's eye and pen to see and record the fact.

At a recent meeting of the Royal Horticultural Society, we read in *The Garden*, Dr. Masters showed ripe fruits of a curious monstrosity known as the Plymouth Strawberry. "It is an alpine Strawberry, in which all the parts of the flower are more or less represented by leaves. The plant was mentioned by old botanical writers, but afterwards disappeared, or was so completely overlooked, that its very existence was assumed to be a myth. Of late years, however, the plant has reappeared in several gardens, and the correctness of the old writers has been vindicated."

Florists are learning that arrangements formed of a single kind of flower, or of two or three kinds at most, are often in better taste than those in which many varieties are combined. But in disposing of our garden and wild flowers in summer we too often fail to recognize this fact. Once in a while, however, one sees an arrangement that could not be bettered. For example, an old lady recently delighted her neighbors in a Boston horse-car by the beauty of an open basket she carried. It was filled exclusively with white and pale pink Sweet Peas, not too closely crowded together, above which rose a cloud of the tiny, delicate white blossoms of the garden Galium.

The current number of *Insect Life* gives an experiment which seems to prove that the white grub, so destructive of lawns, can be easily controlled by the ordinary kerosene emulsion. A white grub (larva of *Allorhina nitida*), had been killing the grass on the Capitol grounds at Washington. The soil was infested to such a degree that an average of six worms were found to every square foot of surface. The ground was treated with the kerosene emulsion, diluted fifteen times, and kept soaked for some days. The result was the destruction of the grubs, with no injury to the grass. No doubt the ordinary white grubs (larvæ of *Lachnosterna*) would be affected in the same way.

Mr. A. A. Crozier writes to *Agricultural Science* to advise the growing of samples of grasses and other forage plants in hills, rather than in small plats or short rows, as is usually done. This brings the kinds near together for comparison, yet leaves them distinct so as to readily catch the eye. The quantity is sufficient to identify the species, and as the plants have better opportunity to develop, the habit of growth is better shown. The hills should be far enough apart to permit horse cultivation, for land is cheaper than labor. The kinds planted will be likely to be so prominent in the hills that ordinary hands may be entrusted to weed them. As usually grown, grass plats become so filled with weeds that their value to the public is greatly impaired. It is well in planting to leave vacant spaces for kinds to be afterward obtained. These may be occupied temporarily with duplicates or with other crops.

The exhibition of the Massachusetts Horticultural Society on August 25th was notable for the display of seedling Gladioli, which has probably never been equaled in the United States. Mr. J. Warren Clark showed a large collection of his new seedlings, in which were a remarkably large proportion of light colors, and the much-sought-for yellows. This collection showed, to a marked degree, the influence of the blood of *G. purpureo-auratus*, or rather of its offspring, the so-called Lemoine race, in the handsome, dark-colored blotch on the lower segments of the perianth, which has always been supposed to mark the descendants of that species. Mr. Clark's collection was remarkable for uniformity of excellence and striking variety of color. Mr. W. E. Endicott, of Canton, exhibited eight Gandavensis and four Lemoine seedlings, with flowers of extraordinary size and beauty. In a small collection staged by Mr. H. B. Watts, of Leicester, was a seedling raised from a Lemoine variety crossed with a Gandavensis which showed no trace of the dark blotch which has heretofore been an unailing indication of the potent Purpureo-auratus blood—an exception worthy of record. Mr. R. T. Jackson, of Dorchester, showed a number of seedlings obtained by crossing varieties of *G. Gandavensis* with *G. dracocephalus*, a species from the Cape of Good Hope, with brownish-yellow flowers. This new race, although hardly "fixed" as yet, is full of promise. The plants are wonderfully vigorous, growing to a much greater height than either of their parents, and flowering freely. The coloring of the flowers is, as a rule, brilliant; and they all show the Dracocephalus parentage in the hood-like upper divisions of the perianth, and in the long, narrow, central lobe of the lower division. The improvement of the Gladiolus and the raising of new seedlings now largely occupies the attention of some of the most intelligent and progressive horticulturists of New England.

The Responsibilities of Florists and Nurserymen.

IN a late issue attention was invited to the important influence exerted by florists, seedsmen and nurserymen in forming the public taste in horticultural matters. In some directions this influence becomes almost absolutely controlling. It is the florist, for example, who decides for all, except a few inquiring amateurs, what kinds of cut flowers and plants shall be used for the decoration of homes and what kinds shall remain practically unknown. Now, no one can wield an influence of this sort without a corresponding obligation, and in this light the growers and dealers in plants and flowers owe it as a duty to their patrons to see that the public taste is developed by being fed on what is good. Especially is this true when they are called upon to decide for those who are not in a position to decide for themselves which of the old favorites among our plants and flowers shall retain their place in popular esteem and which shall be replaced by newer rivals; which novelties shall be accepted as genuine additions to our sources of enjoyment and which shall be rejected as undeserving of favor.

The desire for novelties as such—for things new, irrespective of their intrinsic excellence—is a strong passion in the human breast, and one upon which a trader of any kind is tempted to play. Although we owe to this passion for novelty much that we have gained in all departments of human effort, its results have nowhere been of unmixed good; and in the department of horticulture evil results have often marked its gratification. Consider the prodigious degree to which the lists of cultivated Roses and other flowers have been enlarged. Every season brings new claimants for favor to the front; rivalry in the introduction of novelties often prevents a thorough testing of the merits of older plants; novelty rather than beauty is often their chief merit; and if they are generally cultivated it can only be at the sacrifice of other kinds. There is no room for all these thousand varieties either in the nursery, or in the florist's shop, or in the purchaser's home; and though the public has undoubtedly something to do with deciding which shall be grown and which neglected, the florist's power is infinitely greater. Many persons who buy have

no taste at all in such matters; others are willing to submit their taste to the florist's judgment with regard to beauty; and if the florist makes, not beauty, but mere novelty, his criterion, the average buyer will but too readily fall in with his mood.

Sometimes, it is true, the public is wiser than its purveyors anticipated. For example, an attempt was made last winter to introduce into the New York and Philadelphia markets certain horrors called "dyed flowers;" but they soon disappeared from view, and we were told, upon inquiry, because "the public did not care about them." But when it comes to more delicate questions—as the difference between Rose and Rose—we cannot, and perhaps ought not to depend upon the public taste; and the florist must necessarily know more and should have an acuter feeling for beauty than his patrons. If, in recommending plants or flowers to his patrons, he should consistently make beauty his criterion, and pride himself upon supplying the most excellent varieties in the most perfect condition, rather than those which are "very expensive because they are new and scarce," he would, in the long run, distance his competitors. He might miss a chance now and then of making a temporary "great success" with one novelty or another, but taking month with month and year with year, he would be sure of the best class of custom, and the most of it. The truth is, we think, not that the public, in theory, cares less for beauty than for rarity, but that it finds it harder to be sure of getting it. A purchaser, devoid of confidence in his own taste (and most purchasers are of this sort), knows he can trust a florist when he says a flower is new or rare, but is by no means so sure he can trust him in matters of taste; and in default of the certainty that he will get the most beautiful possible thing, takes the most singular or expensive. If conditions were different, his choice, we believe, would be different, too; and thus it is that our florists' responsibility in this direction is so great.

Naturally, we have not the slightest wish to decry that constant, vigorous and often costly search for novelties which yearly enlarges our sources of enjoyment by giving us newly-introduced species of flowers or newly-cultivated varieties, which are often real acquisitions. It would be a misfortune, indeed, if we were to be forever restricted to our present list of flowers, long and rich though it is. All we wish to say is that there is danger as well as promise in the search for new things, and that the florist should try to preserve us from the danger while bringing the promise to right fulfillment. The private green-house and garden of the botanical enthusiast; the experimental station established by public or individual munificence—these are the places for the perpetuation of plants whose interest lies in their rarity or singularity, rather than in their beauty of form, their splendor or delicacy of flower, or their richness of perfume. Beauty and sweetness in all their myriad varieties are the things that the public really wants, and these the florist should endeavor to supply. A feeling for real excellence should guide and inspire the enterprising search for novelty, as it should be the only test when the acceptance and perpetuation of a novelty is in question.

We are glad to acknowledge that their past history gives us reason to believe that the florists and nurserymen will not disappoint us. As a rule, our florists' shops have always contained more good things than poor ones; more that are recommended by their excellence and fewer by their mere rarity or costliness. Every year shows an improvement in the quality of the flowers offered and in the effectiveness of their arrangement. We see no cause to doubt that our florists and nurserymen will continue to grow in taste themselves, and in a consciousness of their responsibility as agents in the elevation of the taste of the nation; and these words have been written less as words of needed warning than as words of friendly recognition and encouragement.

THE price of White Pine stumpage has increased enormously of late years—several hundred per cent. in some instances, as the great forests of this tree approach nearer and nearer to extermination; but while the price of the finished lumber has also increased, it has not yet reached the point which will exclude it from many of those uses for which it was once almost exclusively employed in this country. White pine lumber is high enough, however, to cause anxiety among lumbermen, and to compel them to find some cheaper and more available material to take its place. The most immediately available wood for this purpose is yellow poplar, as the wood of the Tulip tree is called commercially. It is light and soft, straight-grained and easily worked; it stands well, and when it is not painted it turns with age to a deep rich color. Nashville, in Tennessee, has always been the important manufacturing point for this lumber, as the Tulip tree is found in its greatest perfection along the banks of the streams which flow down the western slope of the Alleghany Mountains; and south of the Ohio and north of the Gulf States it has always been the best local building material. The attention which is now paid to yellow poplar, however, is much more general, and the manufacturers of this lumber are active in their efforts to secure logs and regulate the price of the manufactured lumber. But yellow poplar is not destined to play any very important or leading part in the lumber supply of the United States, and the future of the business is hardly worth considering. The Tulip tree does not form forests by itself, and is not even a considerable element in the forest anywhere. The trees are often very large, but they are widely scattered, and the most accessible have already been cut. There are still great quantities, in the aggregate, of this timber standing, but much of it is now almost too inaccessible for profitable manufacture.

Bass-wood, or linden, a soft and easily worked wood, which is found in considerable abundance in the extreme Northern States, is now used to replace white pine in the manufacture of mouldings and similar objects, for which it is well suited. The quantity of bass-wood, however, is too small to make this tree really important as a factor of the national lumber supply.

Much attention has been paid in late years, as has already been explained in these columns, to cottonwood, southern cypress, and sweet gum as substitutes for white pine. Sweet gum will probably be very largely used before many years, and for some purposes, like flooring strips, it will make an excellent substitute for white pine. The supply, too, is large, and it is likely to last, as the Gum tree grows on land which cannot be used for agricultural purposes.

But the real substitutes for white pine, or rather the only trees now growing on this continent in sufficient quantities ever to take its place, are the Long-leaved Pine of the Southern States, and the Oregon Fir of Puget Sound. These are the trees upon which the American people will have to depend during the twentieth century, or until they are exhausted or a new crop of White Pine grows up in the Northern States and in Canada.

Flowers in Japan.—I.

THERE is no country in the world where flowers are so universally beloved as in Japan. They are inseparable from the life, art and literature of the people, and to deprive the Japanese of their flowers would be to take the sunshine out of their lives. They are enjoyed equally by high and low. The richer classes, in the seclusion of their well-kept gardens, can feast their eyes on the beautiful, while the poor have the benefit of the public parks, gardens and flower-shows, and the poorest of the poor devote a few cents of their earnings to the gratification of their taste.

But in Japan, where everything is characterized by

extreme simplicity, the people are consistent in caring more for the beauty of individual flowers than for the effect of large masses. The graceful and refined lines of a few well arranged flowers and twigs are a never-ending source of pleasure to them and no desire is shown to make a vulgar display of great quantities of blossoms. The art of flower-arrangement, which forms a part of the education of girls of the upper classes, has simplicity for its foundation. It is divided into a number of schools or classes, and a long course of study is required before one can become proficient in either of them. Nothing in the arrangement of flowers is left to accident or to individual taste; it is governed by rules as fixed as those which govern music.

A great variety of flowers follow in constant succession through the different seasons. The snow has hardly disappeared when the early Plum, the prime favorite of all, bursts its buds and is hailed with welcome by the delighted people as the first token of the coming spring. Great gardens or groves of old gnarled, moss-covered Plum trees abound in and about the cities, and thither in the blooming season the people resort *en masse*, dressed in holiday attire, to enjoy an æsthetic feast under the trees and drink fragrant tea. Here they give vent to their delight by inscribing poetic sentiments, too brief, perhaps, to be called poems, and hanging them on the branches of the Plum trees. The Cherry blossoms follow the Plum in quick succession before its latest-blooming varieties have disappeared. The Cherry (Sakura), which almost rivals the Plum in popularity, has many different varieties, single and double, white and pink. But all these trees have the same peculiarity—they bear no edible fruit. They are planted for the flowers only, and so dense is the growth of these, that they resemble great pink and white clouds when seen from a distance. In Tokio the favorite resorts for the people in Cherry blossom time are Umeno Park and Mokojima, the latter being a road which runs along the banks of the Sunida River. Great old Cherry trees line both sides of this road for a distance of five miles, and the branches, meeting overhead, form a perfect canopy of dense blossoms. In the park at Umeno are many exceptionally large trees, some of a variety which resembles the Weeping Willow in habit, and covered with innumerable small pink flowers. Some of these trees are from four to six feet in diameter. At all these resorts temporary tea-houses or refreshment booths are erected. A favorite beverage is Cherry tea, made from last year's blossoms which have been dried and put away for the purpose.

Among later flowers the Wistaria, Pæony, Lotus, Azalea, Iris and Chrysanthemum are the chief favorites. The Wistaria is seen at its best at the celebrated temple-garden of Kameido (Turtle Well) in Tokio. The place derives its name from an old well over which is placed an immense stone turtle. The Wistaria vines are very old and the stems of some of them measure two feet in diameter, while their racemes of flowers, when in greatest perfection, are from four to five feet in length. They are trained over trellises on the borders of the lake, which is filled with enormous golden carp that come to the surface at the clapping of hands to be fed by the visitors.

The Lotus grows naturally and abundantly in all the moats and ponds in and about Tokio and throughout central and southern Japan. The leaves appear on the surface of the water about the beginning of June, and gradually rise until they stand from four to seven feet above the surface, measuring from two to four feet in diameter. The flowers appear about the beginning of August, and continue throughout the month. After the petals have fallen the seed-pods continue to grow, and, while green, form a favorite article of food, as do the long, white roots, which are eaten as vegetables. For Buddhists the Lotus has a somewhat sacred character, and it is often cultivated in the ponds of the temple-gardens by the priests, who use the flowers for altar decorations. Buddha himself is generally represented seated on a Lotus flower, and it

enters very extensively into all forms of Japanese art and decorative work.

The Iris is also a favorite among favorites, and a well-known tea-house-garden at Mokujuma, near Tokio, is celebrated for its annual display of these flowers. The plants are grown here in beds and ditches, somewhat below the surface and partly filled with water.

Flowers are distributed among the people by means of perambulating flower-sellers, and by flower-fairs. The seller goes about the streets carrying two huge bamboo baskets swung from a pole across his shoulders. These baskets (see illustration, page 343) are divided into a number of different compartments, each containing a different variety of cut flowers or leaves. The carrier is sometimes almost hidden by the great mass of flowers and foliage he bears. Yet the construction is light, easily carried, and, like all the articles produced by this people, at once simple, practical and artistic. The common people are the vender's patrons as well as the rich, for, as I have said, the most indigent will buy a few fresh flowers with which to beautify their humble homes.

The flower-fairs or shows take place at fixed dates alternately in the various wards or districts of the city and are held at night. Throughout the preceding afternoon one may see great numbers of farmers and gardeners from the suburbs and the country dragging in their carts filled with all kinds of flowers in pots, as well as with large trees and shrubs with their roots roughly tied up in coarse sacking. When they reach the site of the fair their wares are arranged as temptingly as possible on either side of the street, trees and shrubs at one end and flowers at the other. Innumerable lanterns and torches illuminate the scene. With twilight the first customers straggle along, and by night the streets are crowded with a good-natured, happy throng of men, women and children. Then the bargaining begins, for it is well known to every purchaser that it is the custom to ask from five to ten times as much for the objects offered as the seller expects ultimately to obtain. When the price of a dwarfed Cherry-tree covered with a mass of buds is asked, the gardener answers promptly "one yen, fifty sen" (a yen is divided into 100 sen). The customer shows no surprise, but gravely offers twenty sen. And after many exclamations of "Impossible, honorable master," feints of departure on the part of the would-be buyer, offers to accept intermediate sums, and enthusiastic praises of the beauties, visible and invisible, of the specimen, it is sold, perhaps, for twenty-five sen. Plants are very cheap on these occasions and for a modest sum one can get enough to stock a small garden. But opportunities for the enjoyment and purchase of flowers are not the only attraction of these fairs. Booths for the sale of candy, cakes and children's toys; performances by trained monkeys, birds and dogs; jugglers, musicians and sellers of refreshments surround one until the head is in a confused whirl. But amid all this crowding, noise and bustle the greatest good nature prevails and a more orderly crowd cannot be imagined. As they return to their homes, each person with his burden of sweet-smelling flowers, accompanied by joyous laughing children, one feels that they are indeed the happiest people in the world.

New York.

Theodore Wores.

A Protection for Artificially Fertilized Flowers.

FASCINATING as is the work of cross-fertilizing flowers, there are some annoyances in it that destroy a considerable part of the pleasure. One of the worst of these is the difficulty of inclosing the flowers in sacks after they have been operated upon. The small paper sack, such as seedsmen use, is made of such stiff paper that it is sometimes difficult to tie it about the stem of a flower without injuring some of the delicate organs. Then, after it is attached, it is so heavy that it not infrequently breaks the flower stem, particularly in windy weather. It is quite troublesome, also, to untie the string when it is desirable to remove the sack for the pollination. Sacks made of tissue paper obviate some of the objections, but they introduce another—the thin paper

is so readily wet through by the rain that it will not last.

Some of these difficulties are obviated by the following device: Make small sacks of a very thin, oiled paper, such as nurserymen use for wrapping plants to be sent by mail. Cut them out after a small seedsman's package, as a pattern, leaving the little lappel at the top which, in the ordinary package, is used for sealing it up. Then place a short piece of fine copper wire across the sack, just at the base of the lappel, and paste the latter back over it, as shown in the drawing. This wire serves as a substitute for the string. After the sack has been slipped over the flower, draw the two sides of it

Fig. 53.—Sack for Protecting Artificially Fertilized Flowers.

together with the thumb and finger of the left hand, so that the stem of the flower is directly between the thumb and finger. Then, with the right hand, bring the edges of the sack together and withdraw the left hand, and pinch the neck of the sack snugly about the stem, thus closing it, while the wire prevents it from opening. Then fold down the corner of the sack. The operation requires considerably less time than it takes to describe it, and less than half as long as it takes to tie a string about the neck of the sack. This sack can be taken off as readily as it is put on; it is very light, so that the wind does not cause it to break the peduncle of the most delicate flower; it does not become wet by the rain, and it possesses the additional advantage that the paper being translucent, by simply looking through the sack toward the sun, one can readily see whether or not the ovary has commenced to swell, and thus detect if the operation has been successful. Different sized sacks should be provided to accommodate different sized flowers. For the smallest flowers the sacks need be but an inch wide and two inches long.

I corresponded with a well-known manufacturer of paper bags in New York, to see if such sacks could be cheaply made. In reply, I received some very nicely made duplicates of the sample sent, with the wires inserted, and with the information that they could be furnished at \$1.25 per thousand.

E. S. Goff.

Foreign Correspondence.

London Letter.

BARON SCHROEDER sent some flowers from a few of his choice Orchids to the exhibition of the Royal Horticultural Society to-day. One of these was the extremely rare *Saccolabium Heathii*, which, until lately, was quite unique in cultivation. It is a white variety of *S. Blumei*, from which it differs in no way except in the snowy color of its flowers. The spike shown measured fully fifteen inches in length and every tiny white bloom looks like a miniature bird. The perfume is delightful. This rarity came to view a year or two ago by a chance in an importation of the ordinary *S. Blumei*, and the lucky possessors of it, Messrs. Heath, of Cheltenham, sold it to Mr. W. See, of Downside, Leatherhead, and he disposed of it to Baron Schroeder, retaining, however, a small piece in his possession. This small piece has been secured, I hear, for one of your great American Orchid growers, so that there will be one plant of this Orchid in Europe and one in America. I cannot adequately describe to you the chaste purity of the flower, and, though I am not an Orchid enthusiast, I greatly admire this one. Another choice Orchid from the Baron's garden was *Laelia callistoglossa*, one of Messrs. Veitch's finest hybrids, it being a cross between *L. purpurata* and *Cattleya Gigas*, and I have no hesitation in saying that it is the most splendid *Laelia* or *Cattleya* in cultivation. The flowers are larger than those of any *C. Gigas* I have seen; the sepals and petals are broad and do not curl, as in *L. purpurata*, and in color are a soft

mauve-purple, while the labellum, which is fully two inches across, is of the deepest crimson purple. A four-flowered spike from the Baron of that wonderful hybrid, *Cypripedium Morganice*, showed what a grand plant it is when grown to perfection. It is a cross between *C. Stonei* and *C. Veitchi*, and is exactly intermediate between the parents, the chief attraction of the flowers being the broad, prolonged petals, which are heavily spotted with black on a pale ground. The very distinct and beautiful *Cattleya Schroederiana* was shown in flower. This flower recalls *C. dolosa*, being about the same size and form, and of a uniform, pale mauve-purple color. It is a dwarf growing plant, with pseudo-bulbs about four inches high. Another choice *Cattleya* was *C. Chamberlaini*, a hybrid between *C. Dowiana* and *C. guttata Leopoldi*. The flowers are about the size of those of *Lælia elegans*, and have plum purple sepals and petals, and a labellum of the deepest carmine-magenta. The exquisite little *Lælia Batemanniana*, the hybrid between *Sophranitis grandiflora* and a *Cattleya* of which Baron Schroeder is the only possessor, was shown in perfection, much finer, indeed, than when exhibited here for the first time. The flowers are some two inches across, with sepals and petals of a deep rose pink, or, to be more exact, the color is like that of *Odonoglossum roseum*, while the small lip is crimson, with a golden centre. This priceless little Orchid is, perhaps, the rarest in the Dell collection. One more Orchid is worth noticing, and that is *Cattleya granulosa asperata*, a large flower, with olive green sepals, blotched and spotted with chocolate, and a broad and flat lip of crimson-purple, marbled with white. I have dwelt upon these Orchid varieties because I think it will interest those of your readers who are collecting Orchids, and because we have so seldom an opportunity of describing them.

Celogyne Sanderiana, exhibited at an earlier meeting by Baron Ferdinand Rothschild, and certificated, is worthy of mention after these varieties as, without exception, the finest of all the white-flowered *Cælogynes*, and Orchid lovers look upon it as a grand addition to showy Orchids. In growth it is not remarkable, having globular-oblong bulbs as big as a hen's egg, and long, deep green leaves. The drooping flower-spike carries about half a dozen flowers, each three and a half inches across, with white sepals and a broad labellum, spotted and barred with yellow. No details were given of its native country, but it is presumably an Eastern plant.

Messrs. Cannell, of Swanley, showed several new double varieties of Begonia, of which one was singled out as worthy of a certificate. This was called *C. Stowell*, and has flowers four inches across, very double, of a pleasing cherry rose color; the habit of growth is dwarf and sturdy. A new variety of the Oriental Poppy, *Papaver orientale*, was certificated. It is called *Blush Queen*, and instead of the flowers being fiery scarlet, as in the type, they are a pale pink, with black centre. It is a very striking plant and is looked upon as a great gain to hardy herbaceous plants. Among a number of border Carnations one only was considered worthy of a certificate. This was a sort called *B. H. Elliott*, and has medium sized and very full flowers, with yellow petals flaked and tipped with crimson. Messrs. Paul, of Cheshunt, showed a good collection of cut Roses, among which I noted a few that I thought good although not much known. These included that lovely sort, *The Bride*, which I believe we have to thank an American for. It was shown splendidly and a grower told me he thought it would turn out a first-rate autumn Rose. Another was *American Beauty*, also from your side, and likely to become a favorite here. It is a free bloomer, with petals of good substance and of a rich plum-crimson, if I may so describe an indescribable color. *Lady Darnley* is a new Rose that is a good deal talked about here. It reminded me of *Marie Baumann*, though it is different in color somewhat and the form is not so flat. *Silver Queen*, one of William Paul's novelties, is coming to the front. It is a pale pink sort, with flowers of excellent

form and substance. His *Queen of Queens*, too, which was sent out a few years ago, has been shown well this season, and promises to be a good late Rose. Other new Roses I noticed to-day in fine condition were: *Mlle. Eugène Verdier*, a Tea variety, and *Souvenir de Mad. Alfred Vy*, a hybrid perpetual of a plum purple color. It is almost too early for the second crop of Rose bloom, but if the present favorable weather continues, there will be some fine displays at future meetings.

F. Goldring.

London, August 14th, 1888.

New or Little Known Plants.

Lycium pallidum.

OF the seventy species of *Lycium* known to botanists only *L. vulgare*, a native of southern Europe, the well-known Matrimony Vine of all old gardens, and *L. Chinense*, are commonly seen in cultivation. Two north African species, *L. Afrum* and *L. barbarum*, are sometimes cultivated, although the plants seen under the latter name can usually be referred to the Chinese species. The genus *Lycium* is widely distributed through the dry, extra-tropical portion of the world, with two principal centres of distribution, one in southern Africa and the other in the dry regions of western South America, from which several species extend into the territory of the United States, from California to western Texas, with one species in the southern United States, and another in the Sandwich Islands. None of the species of south-western North America, which are all rigid, spiny shrubs, often forming a considerable part of the shrubby desert-growth, have ever been seen in gardens, with the exception of the one figured upon page 341 of this issue—*Lycium pallidum**—which has now been growing in the Arnold Arboretum for several years. It is the largest flowered of the North American species, and one of the first known, having been discovered in New Mexico by Fremont, in 1844, on the Rio Virgen, one of the tributaries of the Colorado River of the west. It is not a rare plant, being found also in Arizona and in southern Utah. *Lycium pallidum*, in cultivation, forms a spreading bush, two to three feet high, with ashy gray, tortuous, somewhat pendulous branches, sparingly armed with long, slender, rigid spines. The leaves are very pale, spatulate and oblanceolate, an inch or two long. The flowers, which are solitary, or sometimes in pairs from the axils of the leaves, are borne on slender peduncles, rather exceeding in length the deeply five cleft calyx. The funnel-form corolla is nearly an inch long, with broad and rounded lobes, slightly pubescent in the interior towards the base. It is green, sometimes tinged with purple. The berries, which are bright red when ripe, are nearly half an inch long. This interesting plant, as well as a few others, from the dry interior region of south-western North America, has proved, quite unexpectedly, perfectly hardy in the Arboretum, where it flowers regularly every year.

C. S. S.

Cultural Department.

The Cultivation of Native Ferns.—III.

THE cultural directions which accompany the following list of native Ferns are based upon personal experience in growing the various species, with the exception of cases otherwise noted. When special directions are not given, the cultivation described in an earlier article is recommended. In the arrangement of species and nomenclature the classification given in "The Ferns of North America," by Professor Daniel C. Eaton, has been followed. The measurements of species have been taken from plants under cultivation. They are maximum measurements of available specimens, but not greater than may be reasonably expected from established plants under good cultivation. Measurements given in italics are from Professor Eaton's work, as the species

* *Lycium pallidum*, Miers. Ill. S. Am. Pl. 11, 108, t. 67.—Torrey, Bot. Mex. Bound. Surv. 154.—Gray, Proc. Am. Acad. vi. 45; Syn. Fl. N. Am. i. 238.

are not at present in the writer's collection or other accessible ones. All species not otherwise designated are indigenous to New England.

According to Professor Eaton, there are 149 species of Ferns indigenous to the United States. Of this number fifty or more species and many varieties may be cultivated in this vicinity in the open ground or with the protection of a cold-frame in winter.

The list of Ferns which are hardy, or nearly so, could doubtless be much extended by species and varieties from the north-western States, Europe and Japan. In this direction there is a good field for experimenting.

Polypodium vulgare. This common evergreen Fern does not grow very luxuriantly in cultivation. Transplant in tufts or sheet-like masses from the rocks or logs on which it grows naturally and plant under similar conditions in the garden. In planting do not bury the running root-stocks beneath the surface of the soil. Leaf-mould. Eight to eleven inches.

Polypodium Californicum. A handsome species which does well with the protection of a frame in winter at the Botanic Garden in Cambridge. Native of California. Nine inches.

Pellaea gracilis. A tiny gem, one of the rarest, and most difficult Ferns to cultivate. Plant in pots with plenty of

Adiantum pedatum. This beautiful Fern, the Maidenhair, is already in high repute, so there is no need to sound its praises. The ebony black stem and exquisite foliage are known everywhere. This species is easily cultivated, and the fronds attain their greatest beauty in moist, shady spots. It is a very useful Fern for cutting, and a supply is easily maintained for any moderate demands. Leaf-mould. Fronds, twelve to sixteen inches broad.

Lomaria Spicant. This very striking and handsome evergreen species is easily cultivated, but, unfortunately, is not perfectly hardy. A native of the far north-west. Peat and leaf-mould. Frame. Fertile fronds, thirteen to eighteen inches; sterile fronds, shorter.

Woodwardia angustifolia. A rare and very handsome Fern, with bright green, distinct foliage. It is hardy, but is not very easily grown, and is safest with the protection of a frame in winter. Peat and leaf-mould. Fifteen inches.

Woodwardia Virginica. Dark foliage, handsome. Culture as for the last species, but is more easily grown. One to three feet.

Asplenium viride. A rare, charming, dwarf Fern. Close to the following species, requiring the same culture. Plants at Cambridge measure four inches.

Fig. 54.—*Lycium pallidum.*—See page 340.

drainage, or in niches of rocks in a cool, moist corner of rock-work frame. This species would probably do well in a Wardian case in a cool green-house. Specimens at the Botanic Garden in Cambridge measure three inches.

Pellaea atropurpurea is a very distinct and attractive evergreen Fern. Easier to cultivate than the last species, but thrives under the same conditions. Eleven to thirteen inches.

Cryptogramme acrostichoides is a rare, attractive, little Fern, easily grown in pots with old mortar. It would doubtless do equally well in a frame. Indigenous to the far north and north-west. Sterile fronds, three to four inches; fertile, six to seven and one-half inches.

Pteris aquilina, or Brake. This commonest of all Ferns is capable of the most splendid results under cultivation in rich, highly manured soil. It has been grown to the height of nearly six feet, and the fronds laid flat would probably have exceeded that length. Unfortunately, the bed was moved last autumn, so that measurements of finest growths cannot be given. It is a little difficult to transplant, but when it gets established it spreads tremendously, and becomes a nuisance in thickly planted borders. Give it plenty of room, with high culture, and it will become one of the prides of the garden. Fifty-six to sixty-four inches.

Asplenium Trichomanes. One of the most exquisite of all our dwarf species. It does not do well in the open border; but thrives in cool, damp niches of rocks and in pots. Evergreen. Peat and leaf-mould. Frame. Four to four and a half inches.

Asplenium ebeneum. Narrow and comparatively tall evergreen fronds. A very attractive species. Peat, leaf-mould, and a frame in winter, as it is not very hardy. If planted in the open border give abundant drainage. Eight to ten inches.

Asplenium angustifolium. This rare and handsome species is one of the most distinct of our native Ferns. Fronds, tall, light green, once pinnate. The most desirable of the large Aspleniums, and of easiest culture. Twenty-four to thirty-three inches.

Asplenium Ruta-muraria. One of our tiniest Ferns and difficult to grow. The finest seen in cultivation was at Kew Gardens, where some rocks, with specimens growing in pockets, had been moved bodily from the woods to the garden. It may be grown for several years by potting carefully, with plenty of broken limestone drainage. One to two and a half inches.

Asplenium thelypteroides. A tall, dark green species. Desirable, and grows very freely. Thirty to thirty-four inches.

Asplenium Filix-femina. This common species grows in strong, fine-tufted masses, and likes a rich soil. It gets rather shabby during the summer, and therefore should not occupy a very conspicuous position in the garden. A new growth may be induced in midsummer, without injury to the plant, by cutting off all the fronds close to the ground, when a new lot will soon take their place. This Fern is a very variable species, and in England a large number of varieties are cultivated in gardens. Fifty-four varieties are offered in the catalogue of one of the English Fern-growers. Many of these varieties are distinct and well worth growing. Two and a half to three and a half feet.

Scolopendrium vulgare. This beautiful and distinct Fern, known as the Hart's-tongue, is extremely rare in this country, and it is best obtained from dealers, or from England, where it is common. It is not indigenous to New England, but is found in New York and some other parts of the country. It requires the protection of a frame in winter. Peat and leaf-mould are advantageous to its successful cultivation. In England large numbers of varieties of this protean Fern are cultivated; but they are not, for the most part, particularly desirable, unless as curiosities. Moore* describes sixty-six varieties with reniform, incised, curled and contorted fronds of every conceivable shape. Thirteen to seventeen inches.

Campptosorus rhizophyllus. The Walking Fern. This interesting species receives its name from its habit of forming little plants at the tips of the fronds, which take root, grow, and in their turn form plantlets at the tips of their fronds, and thus a carpet of Ferns may be formed. Not difficult to grow in pots or in a cool, moist spot, with peat, leaf-mould and lime rubbish. Evergreen. Frame, five to seven inches.

Phegopteris polypodioides. This desirable Fern spreads rapidly, and makes a low, carpet-like growth of much beauty. It is the earliest comer in spring, having well-developed fronds when other Ferns are just pushing up their graceful forms. Of easiest culture. Fifteen to eighteen inches.

Phegopteris hexagonoptera. A species much resembling the above, but of larger and richer growth; does best with protection of a frame in winter. Fourteen to seventeen inches.

Phegopteris dryopteris. This very beautiful dwarf species is one of the most desirable small Ferns for cultivation, as it is easily grown and spreads quite rapidly, making a lovely light green carpet of delicate fronds; leaf-mould. Eight to twelve inches.

Phegopteris calcarca. An attractive species of low stature; succeeds with a frame in winter, and may be hardy. Found in the West. Peat and leaf-mould. Four to eight inches.

Aspidium Noveboracense. A pretty Fern; fronds light green; delicate. Twenty to twenty-four inches.

Aspidium thelypteris. A marsh Fern; distinct, with delicate, thin fronds, very pretty. Twenty inches.

Aspidium Nevadense. A rather tall, handsome species, with bright green fronds. A native of Pacific Slope. Frame. Two feet.

Aspidium cristatum. A tall, narrow, rigid Fern, sub-evergreen, peculiar in its erectness of habit. A handsome and very desirable species of easy culture. Twenty-five to thirty-four inches.

Aspidium cristatum, var. Clintonianum. One of the rare Ferns, and also one of the finest for cultivation, attaining great height and strength under favorable conditions. Two and a half to three feet.

Robert T. Jackson.

Boston.

Plums for the West.

THE notes of Mr. Williams indicate cumulative troubles in attempting to grow the Plums of western Europe and their seedlings, and a growing interest in our native Plums and their crossed seedlings. At the west the foreign Plums have measurably failed from the beginning of prairie settlement, and our farmers have been constantly experimenting with selected native varieties. As a rule, the Miner, Wild Goose and other sorts of the Chickasaw family have failed to perfect paying crops of fruit, though loaded with blossoms annually. The variety giving the best satisfaction in the way of hardiness of tree, perfection of foliage and regular habit of bearing is the Maquoketa. Although plainly of the Chickasaw species, the original tree was found growing at an early day on the Maquoketa River in eastern Iowa. It is rather later in ripening than the typical Wild Goose, and fully its equal in size and quality of fruit.

The varieties of the *P. Americana* family that have proved hardest in tree, best in foliage and most continuous in bear-

ing during the past twenty years are De Soto, Wolf and Wyant. Even frosty weather during the blossoming period does not appear to prevent a full crop of fruit on these sorts. On mature trees, well cared for, the fruit is large enough, handsome enough, and good enough to compete, in Chicago, with the best varieties shipped in from the South, or even from California, where fruit is usually picked prematurely.

We have many other native Plums that seem to have special local merit, and in time they may take the place of the three sorts named. The traces of curculio are found on many specimens of these varieties, but the larvæ so rarely enter the fruit, that full crops of perfect, or nearly perfect, fruit are the rule, and failures the rare exception.

And now let me direct attention to the varieties of the Plum found north and east of the Carpathian Mountains in Europe. Tourists who are judges of fruits will not hesitate to say that the Plums of eastern Poland, northern Silesia and southern Russia are equal to those found in western Europe. Some of these on trial at the West promise to be hardy in tree, perfect in foliage and early bearers of good fruit, not liable to rot or to the attacks of the curculio. As an instance, I have to-day tested the fruit of the Black Plum of Russia. It is a number of days earlier than Wild Goose, and larger, firmer in flesh and better in quality, for any use, than the latter. It is this year absolutely free from marks of the curculio, and its thinness of foliage will not be favorable for the rot. Though very thick and firm, its leaves are narrow and small, so that the fruit is fully exposed to the air, and even to the sun at intervals. This thinness of foliage seems to characterize the east Europe Plums, even the wild Plums and Prunes of the Volga bluffs.

Ames, Iowa.

J. L. Budd.

The Kitchen Garden.

COLD frames should now be made ready for use. The last days of September or earliest days of October often bring a slight frost, enough to scorch the tops of Snap Beans and Tomatoes, Peppers and Egg Plants. Now, if proper forethought has been exercised, these crops will be grown so that it will now be an easy matter to protect them with frames. Place the frames over the crops at once, and pile the sashes near so that they can be put on quickly. Sashes three feet by six are the handiest for general purposes, and for these four-sash frames are most convenient. These frames are twelve and a half feet long, five feet ten inches wide, eighteen inches high at the back, and twelve inches high in front, and made of pine. These can be carried from place to place by two men, and are used for covering from September till May, and stored up one above the other, four or five deep, during the summer months, or in winter when not in use. Temporary frames may be readily constructed by driving some short, stout stakes into the ground along the back and front of a bed of vegetables six feet wide, and nailing boards (two deep) against these stakes. A light frame-work, shaped like a sash, but covered with "Plant-protecting Cloth" instead of glass, is lighter, easier to handle, and almost as effectual as glass sashes in saving vegetables from early frosts. But as sashes or frames cannot be used for all vegetables, sheeting is a fair substitute. It can be spread over the plants at night and held in place by boards or by spadefuls of earth on the edges. Go to a newspaper printing office and get the calico cloth that has been used in cleaning the presses. It is very strong, one, often two, yards wide, and in lengths perhaps of five to seventy feet. It is just as good for this purpose as new, clean calico. Sew these strips into sheets nine or twelve feet wide, and any length to suit up to forty or a hundred feet. Such a sheet is a capital thing to spread over a bed of Tomatoes or Snap Beans to save them from an early frost.

William Falconer.

Glen Cove, N. Y.

September Rose Notes.

AS the cooler nights of autumn have come, more care should be taken in watering and ventilating the young Roses planted out in the Rose houses during the summer months in preparation for winter forcing. They should now be both rooting and growing freely, and becoming thoroughly established, so as to stand the strain of rapid winter growth. And in watering, of course much depends on the weather, though regular syringing should be given just as often as the weather permits. But, when through any oversight the watering of the Rose houses shall have been postponed until late in the afternoon, it is perhaps better to omit it entirely for that occasion, if the night promises to be cold, rather than to have the plants so drenched with moisture that the foliage has no opportunity to dry before the sun gets up the following

* "The Ferns of Great Britain and Ireland." By Thomas Moore, F.L.S. London: 1857.

morning. Or if the plants should be watered under such circumstances, a light fire should be made in the boiler, so as to dry the house somewhat during the night. Some discretion should also be shown in the matter of ventilation, as no hard and fast rule can be laid down for this operation any more than for watering, the state of the weather being all-important. Proper care should be taken that the tender young growth of

It may be mentioned here that another contestant has entered the race for popularity among the Roses for winter blooming, in the form of the new Tea, The Gem, so-called provisionally by its introducer, a grower in the vicinity of Philadelphia. The Gem is of uncertain origin, as the introducer is not positive whether it is an entirely new variety or simply an old sort re-discovered. It somewhat resembles

A Japanese Flower Vendor's Basket.—See page 338.

he Roses is not exposed to cold currents of air, else mildew will surely appear. It is a well-known fact that some varieties are much more tender in this respect than others, Catherine Mermet, and her charming offspring, The Bride, being among the most susceptible to mildew. In fact, it is sometimes rather difficult to keep the former perfectly clear of fungus at this season of the year. Still, a judicious application of sulphur will work wonders in this respect. But while it is quite necessary that the airing of the houses should be watched, it is not intended that the Roses should be coddled, or kept too close. Give them plenty of fresh air, with proper care in other respects, and the result will be seen in the sturdy growth, and the bright, vigorous foliage, that are sure forerunners of good bloom.

Marie Van Houtte in growth, but is claimed to be far superior to that variety, the flowers being about the size of Perle des Jardins and ivory-white in color, frequently tinted with blush or pink in the centre. But as it has not yet been thoroughly tested, it would be best to reserve a positive opinion as to its merits until a longer experience has proved its qualities.

Holmesburg, Pa.

Orchid Notes.—*Paphinia cristata* belongs to a small genus, which is now included in *Lycaste*. All the species are dwarf and bear large flowers in proportion to the size of the plants. *P. cristata* is the oldest, but is by no means plentiful—probably on account of the difficulty in growing it well. It is a very

W. H. Taplin.

handsome kind. The flowers, usually two, are borne on pendent racemes, and are three inches across, plentifully barred and striped with purple on a white ground. The lip is thick and fleshy, purplish-brown in color, and terminated by a tuft of white bristles. It grows here in shallow pans in a mixture of peat and moss. It should be in the warmest house, liberally supplied with water, and at no time allowed to get dry. *P. grandis* and *P. rugosa* are also in flower, but do not vary a great deal from the foregoing, except that the former has much larger flowers.

Calogyne speciosa is not often seen. It grows about eight inches high, its ovate oblong bulbs being terminated by an erect, leathery leaf. The flowers, usually two on an erect spike, are yellowish-green, about four inches across. The large oblong lip is very handsome, reddish-brown, except the front portion, which is pure white, and beautifully fringed. There are also two prominent crests running nearly the whole length of the lip. It is nearly always in flower and growth, and should be accorded very liberal treatment and be kept in a warm house. Another species now in flower, but differing largely from the foregoing, is *C. corrugata*, so named from its wrinkled bulbs. The erect racemes proceed from the young growths, and bear four to six lovely white flowers, about two inches across. The lip has a deep orange blotch on the crest and longitudinal lines of reddish-brown in the throat. Coming from the Khasya hills, it may be grown with the *Odontoglossums*, and, like them, delights in abundance of water, but care must be taken not to over-pot it.

Trichopilia grata is a very pretty and useful Orchid, resembling *T. fragrans*, and, like it, is very fragrant. The sepals and petals are yellow-green, the large, pure white lip being marked with a blotch of yellow. The racemes are strong, somewhat erect, and four to six flowered. It grows admirably under the same treatment accorded the *Odontoglossums*, but should be kept somewhat drier after growth is matured.

Odontoglossum Harryanum is one of the latest and best additions to this large genus. Owing to liberal importations, it is now quite plentiful, and may be seen in nearly every collection. It appears in many forms, and no two drawings of it are alike. That it is very free-flowering in its native state there is evidence in the stout, dry spikes on the imported plants; and imported bulbs produce good spikes, but I have not seen good spikes on home-grown bulbs. The plant in flower with us is from the first importation to England. It is growing freely, and increasing in size of bulbs, with the *Miltonia vexillaria*, and under the same treatment, but I think it would flower better if given more sunlight and a drier atmosphere. In growth it much resembles *O. hastilabium*. The flowers are very handsome, the sepals and petals being of a chestnut-brown, the former barred and tipped with light yellow; the petals are striped with purple and tipped with yellow; the front lobe of the lip is pointed and pure white; the crest is yellow, while the base is heavily striped with light purple.

F. Goldring.

Notes From the Arnold Arboretum.

THE number of trees or shrubs which flower in this climate after the middle of August is not large. The most important of them, from an ornamental point of view, is the so-called Japanese Sophora (*Sophora Japonica*). This is one of the first trees from Japan cultivated in European gardens, having been introduced into England as early as 1763. It is pretty generally distributed through the eastern provinces of China, both wild and in a cultivated state; and it is now supposed that it may have been one of several plants long believed to be natives of Japan, but really Chinese, and introduced by the Japanese in their gardens. *Sophora Japonica* is a round-headed tree, forty or fifty feet high when fully grown, with cinnamon-brown, scaly bark, and wide-spreading branches, those of recent years covered with bright green, lustrous bark. The deciduous leaves are composed of seven to thirteen pairs of oblong-ovate, acute leaflets, an inch to an inch and a half long, dark green and opaque on the upper, and paler on the under surface. The small, creamy-white, pea-shaped flowers, are arranged in large, loosely-branched, terminal panicles, which about the middle of August often quite cover old specimens. Probably the largest specimens of this tree in Europe are the one in Kew Gardens, one of the first plants brought to Europe, and the still larger and more shapely tree near the palace of the *Petit-Trianon* at Versailles. The finest specimen in America perhaps may be seen in the Public Garden in Boston, although it might be expected to grow more rapidly and to a larger size in the Middle States. *Sophora Japonica* is now used in Italy to a considerable ex-

tent as a street tree, notably in Milan, where some of the new boulevards have been successfully planted with it. Its habit adapts it for such a purpose, as do the lightness of the shade, which its pinnate leaves produce, and its habit of flowering late in the summer, when flowers are more valuable than they are earlier in the season. Young plants, however, do not flower very freely, and this tree requires age before it develops all its flowering capacity. The Chinese cultivate this tree largely in some districts for the sake of the "Imperial yellow dye" obtained from the flowers.

Another Japanese tree is now in flower. It is the Japanese variety of *Rhus semialata* (var. *Osbeckii*). *Rhus semialata* is a widely distributed species from Japan, Formosa, and northern and central China to the Himalaya and Khasia mountains. This tree yields the Chinese galls of commerce, which are believed by the Chinese to possess valuable medical properties. The Japanese variety, in which the petioles are broadly wing-margined between the leaflets, is the only one in cultivation. It is a round-headed tree, eighteen or twenty feet high, with smooth, gray bark, and spreading branches, those of the year covered with a rufous pubescence. The leaves are fifteen or eighteen inches long, composed of four or five pairs of ovate-oblong, sharply pointed, serrate, nearly sessile leaflets. These are six or seven inches long, subcoriaceous, dark green and shining on the upper surface, pale, and covered, as are the petioles, with a soft, rusty pubescence, which is more developed on the prominent mid-rib, and fifteen or sixteen primary veins. The small, greenish-white, short-pedicelled flowers are produced in large, terminal, many-branched panicles. The male plant only is in cultivation in this country, so far as I know, and the fruit has not, therefore, been seen here. It is described as flattened, and densely covered with short, purple or white pubescence. The foliage of this Japanese *Rhus* assumes in the autumn the most brilliant orange and scarlet colors. This character, its neat habit, late blooming and perfect hardiness make this one of the most desirable of the small ornamental trees of recent introduction.

Two North American species of *Clematis*, with cylindrical flowers and semi-woody climbing stems, remain in bloom here all summer long. They are *Clematis crispa* and *C. Pitcheri*. The former is a native of river-swamps from North Carolina to Texas. This species is well marked by its membranous foliage with lax venation, and by the conspicuously undulate margin of the upper part of the sepals, which, when the flower is fully expanded, are reflexed from below the middle. The flowers are solitary, on peduncles rather shorter than the leaves, an inch and a half long, bright purple and very fragrant. The leaves are very variable, ternate or pinnate, the leaflets often deeply lobed, especially those near the base of the stems. There is an excellent figure of this plant in Lavallée's "Les Clématites à grandes Fleures" (t. xiv.), and there are figures in the *Botanical Magazine*, t. 1892, and in the *Botanical Register*, t. 60. It is the *C. cordata*, *Botanical Magazine*, t. 1816; the *C. cylindrica*, *Botanical Magazine*, t. 1160, and the *C. Viorna* of Andrew's *Botanical Repository*, t. 71. *Clematis Pitcheri* is found in the country west of the Mississippi River from Missouri to northern Mexico. It may be distinguished from the last species by its thicker and sometimes almost coriaceous leaves and smaller flowers, which are much darker in color, destitute of perfume and borne on peduncles longer than the pinnate leaves, which are composed of two to four pairs of ovate, obtuse, generally undivided, but sometimes three lobed leaflets. It is well figured by Lavallée, "l. c., t. xv.," who also figures, "t. xviii.," under the name of *C. Sargentii*, a mere form of this species with rather small flowers, raised from seed distributed from the Arboretum. The fact that these American cylindrical flowered *Clematis* are perfectly hardy, and that they continue in bloom during several months, make them of considerable garden value, although neither of them are as showy nor as desirable, perhaps, as garden plants, as the scarlet-flowered *C. coccinea* referred to in an earlier issue of these notes.

But a far more valuable plant, from an ornamental point of view, is the common Virgin's Bower, of all eastern North America (*Clematis Virginiana*), which flowers here during the month of August. It grows naturally in low, wet places, along the borders of streams and swamps, sending its long, climbing stems over bushes and low trees. The creamy white and very fragrant flowers are produced in great profusion in loose, axillary clusters, making this plant, next to the Clethra, the most attractive and interesting of the native shrubs which bloom here at this season. The fruit-clusters, with their long and conspicuous feathery tails, which succeed the flowers in autumn, add materially to the ornamental value of this plant. The Traveler's Joy (*Clematis*

Vitalba), a widely distributed species of central and southern Europe, and very similar in general appearance to *C. Virginiana*, but with white flowers, is, on the whole, perhaps, more attractive as an ornamental plant.

August 20th.

The Forest.

European State Forestry.

THE State Department has done a good piece of work in collecting in one volume the reports of our consuls on "Forestry in Europe."* This volume contains a great deal of interesting and valuable information, but, unfortunately, shows the lack of an editor, who might have sifted the relevant from the irrelevant, and by condensation and the avoidance of unnecessary repetitions might have brought out the prominent features which are of value to the American student. There are also found some misleading and sometimes erroneous statements, which are due to misconceptions of the real situation on the part of the consuls.

This is, perhaps, not easily avoided, for it requires a considerable and intimate knowledge of the conditions prevailing in the different European states in regard to their forest management—and the difference in these is great—in order to be able to properly present the facts and to generalize from them.

The ideas which in general prevail in regard to the activity of the governments in Europe with respect to forestry are more or less erroneous, and the present publication is hardly apt to set them aright.

There is a belief that the forests of Europe are mostly in the hands of government, or at least under government control. What is true for a very small part of the country is made to appear universal, and thus the misconception arises.

From a survey of more than three-quarters of the European forest area, including that of Germany, Austria, Switzerland, Italy, France, Spain, Russia, Sweden and Norway, we may draw, then, the following conclusions as to the position which these states take towards forestry interests, and correct the erroneous views existing in this respect.

1. The governments, excepting in Russia, own the smaller part, in many instances only a nominal area of the forest lands—namely, altogether not more than sixteen to twenty per cent. of the total European forest area.

2. Private individual owners enjoy their forest property almost everywhere without interference on the part of the government.

3. Communities—villages, towns and cities—and "eternal" corporations, like churches, colleges, etc., very often own large tracts of forest land as common property. Over these the state, in many cases, exercises supervisory powers, with a view of preventing the waste and depreciation of this common property, acting *quasi* as guardian or trustee, as in other corporated interests. Wherever supervision of private forest property is exercised it is almost always done only after full demonstration that the common welfare, the interest of the many as against the few, demand it, and full indemnification for damage sustained is given in every case.

4. The idea of State supervision in given cases where the danger to the community from forest devastation or destruction is demonstrated, is not an old but a decidedly modern one, having found expression in legislation only within the last twenty to thirty years; mostly within the last fifteen years. While in all other directions of economic life European governments are working towards non-interference and liberation from government restrictions, in the question of forest management the opposite tendency is developing, the necessity for such government supervision on account of various peculiarities of forest property and forest management being more and more recognized.

All European governments, without exception, have felt themselves in duty bound to encourage and aid proper forest management and all efforts at reforestation. This is done:

(a.) By setting a good example in the management of the forests belonging to the State.

(b.) By offering an opportunity of acquiring the necessary knowledge in forest schools and encouraging the employment of trained foresters.

(c.) By aiding and encouraging reforestation, where it appears necessary, with active financial aid.

It may be stated as of special interest to us that nowhere in these States exists there a bounty system, and where it did exist, as, for instance, in France, it failed to produce the results looked for; while the supplying of plant material, free of

cost or at the cost of packing and transportation, and encouragement by the advice and suggestions of forestry officers, or a direct money expenditure for specific purposes of reforestation, have everywhere been practiced with gratifying results.

We also see that the conviction is gaining ground among governments and private citizens, monarchies and republics, that the forests located in certain places serve a more far-reaching and important purpose than that of mere supply of material. Such forests, called protective forests, are, nevertheless, managed with a view of obtaining the material; in such manner, however, that the forest influence may not be disturbed. Forest preservation, in the sense of keeping forests intact and preventing the utilization of their material, is practiced nowhere; it is protection against damage and devastation and proper management that is meant by forest preservation.

Washington, D. C.

B. E. Fernow.

Correspondence.

The Boston Public Garden.

To the Editor of GARDEN AND FOREST:

Sir.—There is so much that is good in the Public Garden in Boston, and its possibilities of improvement are so great, that it is incumbent upon any one who cares either for gardening or for the best interests of the public to raise a voice in criticism of its present condition in behalf of the better condition to which it might so easily be brought.

Its situation in the heart of the city, and in connection with the Common, is fortunate. Its architectural surroundings are more agreeable than those, for instance, of any small park in New York. Its surface is perceptibly, yet gently, modeled, just as one would wish to have it. It embraces a pretty sheet of water and contains many trees, which, although not yet of very large size, are good and promising specimens. In short, the blocking-out of the garden, so to say, is excellent, and if the details of its execution were as good, it would be one of the most charming urban spots in the world. But, it seems to me, these details are so unfortunate, that it is a warning rather than a model.

For some of them the authorities now in charge are not responsible—for the stone coping which surrounds the water to the injury of naturalness of effect; for the statues, which are far from being satisfactory works of art, and for the bridge, which is not only ugly in design, but almost big and heavy enough to carry a railroad. These details it might be difficult to change. But something might be done to mitigate their defects; the bridge supports and parapets might be clothed with vines, and the masses of shrubbery around the pond might more often be brought down over the coping to the water's edge.

It is, however, details of more recent origin, which most seriously injure the beauty of the spot—details which come under the head of gardening proper. Let us stand for a moment on the bridge and see what the outlook offers.

Do we find unity or harmony in any direction? I think no fair-minded observer can say, Yes. The bridge itself crosses the long pond about midway of its length, and forms part of a straight walk which traverses the garden from west to east. Winding paths diverge from this straight walk in all directions, and the first thing we note is that there are far too many of them, and too many wide, graveled spaces where they intersect. Public convenience does not demand so great an expanse of gravel, and beauty is greatly lessened by the degree to which the lawns are cut up, and unity and reposefulness of effect are thereby injured. Next we notice that there is far too much color in the landscape. Green is the color with which nature paints a landscape of this soft, intimate sort, varying it with innumerable shades, but always keeping the medium shades preponderant, and using the lightest and darkest, and above all the brightest, for accentuation only; sprinkling it with the vivid hues of flowers, but keeping these likewise subordinate to the general soft, verdurous tone. Of course, in a garden man cannot follow nature's example with strictness. As he must innovate upon her disposition of surfaces, so he may upon her use of color, but never to such a degree that her ideal is altogether lost to sight. Now, in the Public Garden, color is much too profusely used, alike in the way of bright or variegated trees and shrubs, and in the way of brilliant low plants and flowers. And it is also badly used. Look off towards Boylston Street, for instance, and the most conspicuous object is a group of trees on the edge of the water, a Golden Poplar

* "Forestry in Europe."—Reports from the Consuls of the United States.

between two very light-colored Willows—the combination ugly in itself, and not properly softened by masses of a soberer hue. And then look in every direction at the scores of formal flower beds planted solid with the crudest hues that the ingenuity of the gardener's craft has been able to produce. Were nine-tenths of them away the garden would profit immensely, and the value of the remainder would be as greatly increased. There is often a place for such beds in a garden design, and in the Public Garden there is a very good place. The long, straight path, taking in the conspicuous bridge and ending at Washington's statue, is a formal feature dictated by convenience, and might appropriately and with good effect be bordered throughout with formal beds. Thus the garden would be enlivened, yet its more natural parts would not be disturbed, and the taste of the public for such beds would be as well met as by the multitude of beds which are now misplaced. Misplaced they are indeed. Nowhere can one walk a hundred steps without coming upon a new one, nowhere can one look in the hope of finding a restful verdant view without seeing them scattered about at random in the most glaringly false situations. Nor is it easy, upon examination, to find one of them which is intrinsically good in color. The *Coleus* "Golden Bedder," with its vivid, impure yellow tint, and the "Crystal Palace Gem" *Geranium*, with its cherry-colored blossoms in contrast with yellow-green leaves, are among the most hideous products of recent horticulture, and some of the *Alternantheras* are almost as bad. Yet it would be impossible to count the hundreds of these plants which have been employed; and even when better ones are used they are seldom well combined. Greatly as the modern gardener loves the bedding-out system, he has small idea of the possibilities of beauty it might possess in hands guided by a good eye for form and color. The "crazy quilt" seems to be the work of art which he most earnestly desires to rival. There is, however, at least one instance in the Public Garden of a really good design—the central panels, to north and south of the border which encircles Washington's statue, and which is chiefly composed of those succulent-leaved, low-growing, formally-shaped plants (*Sedums* and *Echeverias*) which above all others are adapted for the purpose. Here the combination of a brown-leaved *Oxalis*, starred by a few small yellow blossoms with the pink-streaked blue-grays of *Stone Crops*, is admirably accomplished as regards both line and color. If the edging close to the statue and the intervening *Palms* were removed, and if all the panels of the border were as good as these two, the arrangement would be a model of excellence, alike in execution and in application.

But these formal beds of gaudy color are not the only things which help to make the Public Garden as restless and inharmonious as possible. Wherever, on the edges of the lawns, there is not a bed, there is sure to be a tropical plant utterly out of keeping with its environment—a *Screw Palm*, an *Agave*, a *Yucca*, an *Araucaria*, a *Dracæna*, or an *India-rubber tree*. Or if not one of these, then a tree or shrub with vivid leaves or an eccentric form. Looking northward from the bridge, for instance, one sees, to the left of the water, first a vase filled with an intermixture of hardy and tropical plants, then a *Golden Poplar*, a yellow *Retinospora*, a *Kilmarnock Willow*; then a *Golden Elder* in a pot, backed by a small *English Elm*, another *Golden Poplar*, and a wand-like *Irish Yew*; then a little *Weeping Willow*, and a half dead, pendulous *Purple Beech*, overhanging an immense bed of *Coleus*, in the shape of a double horse-shoe; this between the winding path and the water, and across the path another big bed casually placed on a sloping piece of lawn and flanked by an *India-rubber plant* and a *Dracæna* that looks a good deal like a broom on end—all within the space of a few feet, in a spot where surely some natural arrangement was called for, and all in no sense combined or disposed, but spotted about at random. It is needless to ask where is the peacefulness, the repose, of such a landscape passage—where is its sense, its beauty of any sort? It has variety enough and to spare, but no trace of unity; contrasts of the most glaring kind, but no faintest shadow of harmony. Nothing helps the effect of anything else, and nothing looks well in itself being so palpably out of place. Of these poor, misused, forlorn looking tropical plants, something the same may be said as was said of the formal beds—both because they are known not to be natural products of our clime, and because they are formal, architectural, in expression, their place is in combination with architecture. On the bridge, or by the pedestal of a statue, some of them might look well. Mingled with shrubberies, or isolated on a lawn, they are ruined themselves and ruin their surroundings.

More than this might be said of the defects of the public

garden—something, for instance, of the many vases which are also isolated on the lawns and even in the middle of the pond; of the plot which is filled with *Aloes*, *Agaves* and *Cacti*, in futile imitation of a Mexican garden, crowded together so their own forms do not show, and as out of place here as a giraffe between the traces of a Boston Herd; of the rock-garden built up under an *Elm tree*, in a flat situation, and filled with another heterogeneous mixture of inappropriate plants. But all I wish to do is to beg the many lovers of nature and lovers of art who daily cross this garden to stop a moment and ask themselves whether it is really as it should be, and, as well as I could, to indicate the point of view from which such an inquiry should be made. And for this purpose surely enough has been said.

M. G. Van Rensselaer.

Marion, Mass.

[The Public Garden in Boston has many defects, and it certainly does not represent, as might perhaps be expected, the true and actual condition of the gardening art in this country, as judged by its best examples. It must be said, however, that the garden has been greatly improved under its present management, and that in several respects it is much less objectionable than it was a few years ago. It is now much better kept in every way than formerly; the number of flower-beds has been reduced, and several useless walks have been done away with. The radical faults with the garden have come largely from an entire disregard of any fixed or established plan for planting, if any one has ever had any such plan or any clear or definite idea on the subject. Flower-beds have been made, and trees and shrubs have been stuck in year after year, not as a part of a carefully studied plan, but haphazard, here and there, or wherever a piece of open turf seemed to offer an opportunity to place a horticultural novelty. The result has been that the garden is now spotted over in every direction with the most incongruous, and often the most absurd, plants, and that there is nowhere, in a garden of twenty-five acres, a single quiet stretch of turf or a single spot where the eye can find repose. This feeling of a want of restfulness, too, is increased by the fact that the boundaries have been left too much exposed, so that it is impossible, within the garden, to obtain anything like a feeling of being in the country. The cost of maintaining the garden is enormous; much of this money could be saved and the garden immensely improved, if half the flower-beds and a great many of the walks were turfed over. The bedding gardening, both spring and summer, while perhaps no worse in design and execution than that seen in Hyde Park and in Battersea Park in London, certainly is not artistic. The plants are not always well selected and the combinations of colors are often appalling. The truth is, that the artistic arrangement of bright colored flowers or foliage plants in masses, whether they are *Tulips* or *Coleus* and *Scarlet Geraniums*, requires great artistic feeling, long practice and rare good judgment. Gardeners rarely possess the first of these qualities, while artists, who might make harmonious combinations of color, lack the technical knowledge and the interest in such combinations. The strongest argument against the bedding out system as a system is found in the difficulty of finding men who can do it in a truly artistic manner. The French make such combinations of color better than any other people, but even in Paris really good combinations of colors are rather the exception than the rule. English work of this sort, as might have been expected, is certainly far inferior to the French, while outside of Chicago, and possibly Pittsburgh, there is nothing so bad in the United States as the bedding in the public and many of the private English gardens. Another objection to elaborate bedding gardening—and this is true as well of any absorbing specialty in gardening—is that it inevitably leads to the neglect of other departments. The Public Garden well illustrates this. Constant daily attention is given to the flower-beds, which are weeded and pinched and cut religiously, while the grass is allowed to be overrun with weeds, the edgings of the walks are

neglected, insects swarm upon the trees, and the pond and fountain-basins are foul and filled with rubbish. The tropical plants stuck about the garden, to which our correspondent calls attention, are a new feature, which, with the hardy and half-hardy shrubs, plunged in pots wherever a place can be found for them, only serve to decrease its beauty and diminish its real usefulness. The money which it costs the city to buy these plants, and build and heat the green-houses in which they must be stored in winter, might be spent more wisely in destroying injurious insects or in cleaning the filth from the pond. The Boston Public Garden is visited by thousands of people every week. Its educational importance, therefore, is great—greater, probably, than that of any other garden of its size in the United States. It is a misfortune, therefore, not only for the people of Boston, but for those of the whole country, that it cannot be made to express the real meaning of what such a garden should be.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—Referring to the article on "The Street Trees in Washington," in *Harper's Magazine* for July, let me say that nine years ago I examined these trees in company with the late Dr. John A. Warder. We thought it a good idea to plant these common, rapidly-growing trees to make shade, while valuable trees, that grew more slowly, were being established, and regretted that they were planted so closely as to give insufficient room for the permanent trees that we supposed would be planted between them to take their places. It seems from Mr. Peter Henderson's remarks that these trees were intended to remain. Of the 63,014 trees planted, 43,914 are of Silver Maple, Box Elder and Poplar. The climate of Washington would admit of a selection of street trees that could not endure the climate of our Northern cities. In that climate especially trees should be selected which hold their leaves fresh in the late summer months. The Silver Maple, Box Elder and Poplars (over two-thirds of the whole number planted) are certainly not the best that could be selected on that account. Compare them in this respect with the Sugar Maple, the Cucumber tree, "*Magnolia acuminata*," the Tulip tree, the Oaks and many others.

The foliage of the Silver Maple is poor in the late summer compared with the above named, and, besides this, the branches are brittle, and the trees are disfigured with broken and dead branches before growing old. The foliage of the Box Elder is quite dense and rich in color early in the season, but never fresh in the latter part of the season after it has reached the age of twenty-five or thirty years, and especially away from the margins of streams. Nearly all the Poplars, with the exception of the Lombardy, are a nuisance in the streets in early summer, shedding their down like rain upon the just and the unjust.

If longevity is taken into consideration, how will the Silver Maples, Box Elders and Poplars appear when fifty years old? Here where I write (Hanover, New Hampshire) the White Elms and Sugar Maples, a hundred years old, line the streets, and are noble trees still. Does any of these 43,914 trees compare with the White Elm? Will any one of them endure the city smoke better than the White Elm? I am not finding fault with what has been done, I only wish to call attention to what has not been done. No trees would make a shade quicker nor so cheaply as these 43,914 trees, and if they shade the streets for even twenty years they will have paid their way, but it is already time to arrange for filling their places. Seeds of trees of valuable and durable kinds should be sown now, the trees grown and transplanted, with plenty of room, so that they will be strong and vigorous before being planted into the intermediate spaces. Then the soft-wooded trees can be cut back on the sides, more or less, allowing the newly-planted ones room to become well established, and by that time the White Maples, Cottonwoods and Box Elders will be in a failing condition.

Robert Douglas.

[This letter was written before Mr. Douglas had seen an editorial article on the same subject in this journal.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—The quotation from an article entitled, "Among My Weeds," in a recent issue of GARDEN AND FOREST, brings to mind some "weeds" of my own cultivating—among them the Poke. It is a matter of wonder that the Poke has not a place in beds where strong, vigorous plants are growing. It is an exceed-

ingly distinct and picturesque plant. The rich colors of its stem and its graceful manner of growth are especially noticeable. A marked trait is, that on the same spray, where the berries are ripe, there will be not only green berries, but flowers and buds. The stem of the spray alone is remarkable for beauty. I have stripped them of the berries and arranged them in a vase-bouquet, and every one was desirous of knowing what the new and rich-colored thing was. So with the flowers, which are unique and pretty. A party of visitors once gathered around a plateau of flowers in which I had arranged the Poke blooms, and were curious to know what sort of Wax-plant it was. The odor of the plant is not pleasant, but this is slight in the flower, if at all noticeable. I raised my crop of Poke from seed, but as the plant is perennial, it will come up from year to year, faithful to the appointed time.

Recent Publications.

Bulletin of Miscellaneous Information.—Royal Gardens, Kew, No. 19, July, 1888.

This, the last number of the useful publication which has reached us, like its predecessors, is filled with valuable information. It contains, among other articles, the following: On Bhabur Grass (*Ischæmum augustifolium*), with a figure, a plant closely resembling the well-known Espartu Grass in habit and in qualities, which make it valuable in the manufacture of paper. Bhabur Grass is a native of northern India, where it grows on dry, bare slopes, and is used mostly in the manufacture of cordage. It is believed that this plant, were it cultivated on a large scale, might become important in furnishing excellent material for paper-making, and that it can be easily cultivated this paper gives abundant evidence.

(2) On the Cayman Islands, a group of three small islands—Grand Cayman, Little Cayman and Cayman Brac—situated in the Caribbean Sea about 200 miles west of Jamaica, and rarely visited by travelers. They contain, however, a population of more than 4,000 persons, who are described as temperate, strong, tall, healthy-looking people, chiefly white or colored, "and who are doubtless descended from the original settlers of the last century." The population of black people is comparatively small. The vegetation of their islands is similar to that of Jamaica, as are the crops, which are principally Sugar-cane and Cocoa-nuts.

(3) On the Prickly Pear in South Africa, being a discussion of the best methods for exterminating the Prickly Pear from South African fields, and of the uses to which these plants can be applied, by Prof. MacOwen, director of the Botanic Garden in Cape Town in South Africa. It is based upon the rapid spread of the Prickly Pear, as one or more species of *Opuntia* are called, in all dry regions of the Old World. These plants are of American origin, but they are as much at home in the Old World as on their native Mexican plateau. They render the land they occupy worthless for all purposes of agriculture, and it is becoming, therefore, a matter of real importance to determine how such plants are to be effectually eradicated at a small cost, or if they cannot be eradicated, how they can be profitably cultivated.

There are also articles in this issue upon *Valonia* (the acorn cups of *Quercus Ægilops*), of which large quantities are imported annually into England from Greece and Asia Minor, and upon Star Anise—*Illicium verum*.

Recent Plant Portraits.

CATLEYA WALKERIANA, *Revue de l'Horticulture Belge*, June. Rhododendron MAIDEN'S BLUSH, *Revue de l'Horticulture Belge*, June; one of the earliest of the race of green-house Rhododendrons raised by the Messrs. Veitch, and derived from *R. javanicum*.

HAKEA LAURINA, *Bulletino de la R. Societa Toscana di Orticultura*, June.

Rose BARDON JOB, *Journal des Roses*, May; a handsome Tea Rose, with semi-double scarlet flowers, raised from the well known Gloire des Rosomanes by Narbonnard & Sons, of Golfe Juan, and recommended as a strong-growing pillar Rose, or for bedding.

BAHIA (ERIOPHYLLUM) CONFERTIFLORA, *Gartenflora*, June 15th; a half shrubby Californian Composite, with small heads of yellow flowers.

CHEENACTIS TENUIFOLIA, *Gartenflora*, June 15th; a loosely-branched, diffuse Composite from the coast of southern California, like the last, of little horticultural interest.

ANTIARRHINUM NUTTALLIANUM, *Gartenflora*, June 15th; a late

California species, with slender, sprawling branches, small leaves, and minute purple flowers, of no interest as a garden plant.

TRICHOPILIA LEHMANNI, *Gartenflora*, July 1st.

ZYGOPETALUM BRACHYPETALUM, var. STENOPETALUM, *Gartenflora*, July 15th.

ASTER ALPINUS, var. SPECIOSUS, *Gartenflora*, July 1st; a stately variety of a well known and widely distributed plant, discovered by Dr. Albert Regel, on the high mountains of central Asia.

GLOXINIA GESNERIOIDES, Charles Schubert, *Wiener Illustrirte Gartenzeitung*, June.

IRIS KOROLKOWII, *Gardener's Chronicle*, July 14th.

PINUS SABINIANA, *Gardener's Chronicle*, July 14th; the well known Digger Pine of California, figured from a specimen grown in the gardens of the Villa Thuret, at Antibes, in the south of France.

OSTROWSKYA MAGNIFERA, *Gardener's Chronicle*, July 21st; a wonderful Campanulaceous plant, discovered by Dr. Albert Regel on the mountains of Chanat Darwas, in eastern Bokhara. "It is a hardy perennial, with tuberous roots. As shown, the stem is three feet in height, green, sprinkled with small red spots, with four-leaved whorls at intervals. The leaves are glabrous, rather fleshy, shortly stalked, oblong-acute, coarsely toothed. The inflorescence is cymose, the flowers on long stalks, at first pendulous, afterwards nearly erect; when fully expanded they measure five and three-quarter inches in diameter. The plant, despite a paleness of color in the flower, is certainly one of the finest herbaceous plants ever introduced, and as there can be no doubt as to its hardihood, and little or any as to its adapting itself readily to cultivation, it is sure to become a popular favorite."

The plant from which this illustration was made was exhibited by the Messrs. Veitch at a late exhibition of the Royal Horticultural Society of England.

Notes.

A young Apple-tree in a yard on Washington Street, near Eggleston Square, Boston, was in full flower on the 2d of September.

Mr. Albert Koebele, an agent of the Entomological Division of the Department of Agriculture, has sailed for Australia to study the parasites affecting the cottony cushion scale, especially in the interest of horticulture in California.

It is expected that not more than one million pounds of tobacco will be raised in Egypt this year, although, on the average, thirteen million pounds have been produced in former seasons. The decrease is owing to the recent action of the Khedive in putting a tax of \$157.50 on each acre of ground devoted to this crop.

At the late convention of Florists a resolution was adopted to the effect that it would be of great advantage to the trade if manufacturers would unite to make pots of uniform size, and members of the Society are invited to sign a circular stating that henceforth they propose to use no other pots than those of the standard size adopted by the Society. A copy of this circular is to be sent to all the potters in the country.

Mr. John J. Thomas reports in the *Country Gentleman* that an orchard of Bartlett pears, in which the trees were sprayed with Paris green, show scarcely a defective specimen of fruit, while on another tree, forty rods distant, which was not treated with the poison, nearly every pear is disfigured by the codlin worm in the core and by the curculio on the surface. The Bartlett pear, from its earliness and texture, is particularly liable to attacks of the curculio.

Mr. F. W. Burbidge describes, in a recent issue of the *London Garden*, an interesting specimen of the Sycamore Maple, with bright red fruit, growing in a garden near Dublin: "The tree itself in growth resembles the type, but the leaves are smaller and of a more shining or glossy green, being glaucous behind. The leaf-stalks or petioles are bright red, and the fruits, instead of being in dense or short clustered racemes of a greenish hue, are borne in long-stalked clusters, and are red, verging on crimson when fully exposed to the sun." Nothing is known of the history of this tree.

In speaking of the Rose American Beauty at the Florists' Convention, Mr. Edwin Lonsdale said that it could be obtained from January till December, and not September, as was reported. The fact that it can be had at all seasons gives this Rose a special value, although, in order to give a fair profit, where artificial heat is needed, it ought not to sell at wholesale

for less than twenty-five dollars a hundred. Mr. Lonsdale finds that in some cases it does better the second year after planting. American Beauty is at this time the main dependence of New York florists for long-stemmed Roses, and brings at retail from three to four dollars a dozen.

The *Revue Horticole*, in a recent issue, calls attention to *Choisya ternata*, which it considers the most desirable of all early spring-flowering shrubs. It is a Mexican evergreen, belonging to the same family as the Orange, with beautiful, dark green, shining foliage, corymbs of numerous pure white, deliciously fragrant flowers, which are produced in the greatest profusion during the months of April and May. The flowers remain fresh for a long time when cut and are well adapted for bouquets. This plant is not, unfortunately, hardy in the Northern States, but it would probably succeed anywhere south of Virginia, or in California, where it will, doubtless, find itself perfectly at home.

Hybrid Gladioli were again the floral feature at the meeting of the Massachusetts Horticultural Society, held on the 1st of September. Mr. J. Warren Clarke duplicated his remarkable collection of seedlings shown the previous week; and Mr. James Cartwright, of Wellesley, sent an equally large collection of almost equal merit. Indeed it would be difficult to say which of these two collections contained the largest number of really valuable varieties. Mr. Hunnewell exhibited a dish of twelve Late Crawford Peaches from his orchard-house. The twelve weighed six pounds six ounces, the largest measuring eleven and a half inches in circumference and weighing eleven and a quarter ounces. Such a dish of Peaches, it is safe to say, has never been seen in Boston before. A dish of Red Bietigheimer was conspicuous in a large collection of summer Apples, exhibited by Mr. Samuel Hartwell, of Lincoln. This is one of the largest and handsomest of the summer Apples, with a smooth, whitish-yellow skin, beautifully shaded with red. Its firm texture and sub-acid flavor, however, make it a better cooking than dessert fruit.

The second annual convention of the Association of American Cemetery Superintendents was held in the Clarendon Hotel, Brooklyn, last week. At the meetings on Wednesday and Thursday a number of papers of great merit were read on important subjects of practical interest. Among them were the following: "An Ideal Cemetery," by Mr. F. Eurich, of Toledo, Ohio; "Landscape Gardening in Cemeteries," by Mr. R. D. Cleveland, of Minneapolis, a son of Mr. H. W. S. Cleveland; "Lawns," by Mr. W. Salway, of Cincinnati; "Roads," by Mr. O. C. Simonds, of Chicago; "Green-houses and Flowers," by Mr. J. E. Barker, of Boston. The members of the Board of Officers—whose names and addresses have been given in an earlier issue of this journal—were unanimously re-elected. It was decided to hold the next convention at Detroit, in the third week of August, 1889. This association is an organization, the existence of which is full of promise for the better ordering and management of American cemeteries, and it will doubtless have an increasing measure of support from the superintendents and trustees of cemeteries throughout the country.

Every one who has visited Montreal in August will remember the enormous Cantaloupe Melons and their fine flavor. They are almost round, flattened at both ends, deeply ribbed; the skin green and netted, and the green flesh very thick. After some ineffectual attempts by Boston dealers to import these Melons, the growers about that city have been making experiments with them, and Mr. W. H. Allen, of Arlington, has achieved a striking success. According to the *American Cultivator*, he imported his seed direct from Montreal and started them under glass with a moderate bottom heat. In fact, he kept the melons under glass as long as he could. One important point in their culture is to water the vines freely, yet after the Melons commence to form, the fruit should not be wet. The growers in Montreal place a small pane of cheap glass under each Melon to prevent contact with the earth. Mr. Allen and other successful growers about Boston always import their seed each year direct from some trustworthy concern in Montreal. Mr. Allen produced fine, ripe specimens this year as early as August 1st, two or three weeks earlier than the ordinary Cantaloupe. He sold the largest and most perfect-shaped Melon of the variety ever seen in Quincy market for three dollars. It weighed nearly thirty pounds. He sold them by the box at one dollar and twenty-five cents each, weighing eighteen to twenty pounds to the melon. The price soon dropped to one dollar each and is now about seventy-five cents.

The Rejuvenescence of Old Trees.

THE fact that old and apparently decrepit deciduous trees can be rejuvenated by judicious pruning, is not well understood in this country, where old trees, which might perhaps be made to live a century or two, are often allowed to perish unnecessarily. The death of a tree can generally be traced to a gradual failing of vigor due to insufficient nourishment, or to internal decay, the result generally of neglect. The first indication of danger usually appears at the top, and when the upper branches of a tree begin to die, it is a sure indication that, unless radical measures are taken to check the trouble, it can only live a comparatively short time. Vigor can be restored to a tree in this condition by shortening all its branches by one-third or one-half of their entire length. The only care needed in this operation is to cut back each main branch to a healthy lateral branch, which will serve to attract and elaborate, by means of its leaves, a sufficient flow of sap to insure the growth of the branch. This is essential in good pruning, and, if neglected, the end of the branch will die back to the first lateral branch or bud below the cut, leaving a point of danger to the tree. Care, too, must be taken to shorten the branches in such a way that the lowest will be the longest, that the greatest possible leaf surface may be exposed to the light. Figure 1 will serve to show how an ancient Oak should be pruned for the purpose of increasing its vigor.* The vigor of a

Fig. 1.

* We are indebted to the Trustees of the Massachusetts Society for Promoting Agriculture for permission to reproduce these figures, which are extracted from Monsieur A. des Car's work upon Tree Pruning, of which an English edition was published in 1881, by the Massachusetts Society, under the title of "A Treatise on Pruning Forest and Ornamental Trees," a work in which the whole theory of pruning is clearly explained and illustrated.

tree depends upon the power of its leaves to elaborate plant food. The larger the leaf surface exposed to the light, the greater will be the vigor of the tree. The object of pruning, therefore, is to increase leaf surface. If half of a branch of a decrepit tree, bearing small and scattered leaves, is cut away, the leaves which will grow upon the half which is left will be so large that their total area will often be more than double the total area of the leaves upon the whole branch before it was cut. The truth of this statement can be easily verified by cutting down to the ground in the spring a feeble seedling Oak, or, indeed, any young seedling tree, when a tall, vigorous shoot, twice the height and diameter, perhaps, of the slender stem it replaces, will appear at the end of a few months, and,

Fig. 2.

although this shoot will only produce a few leaves, its greater vigor is due to the fact that a larger leaf surface is presented to the light by these few large leaves than by the more numerous smaller leaves of the original plant. The vigor, too, of a tree, can be increased after it has been pruned by a good top dressing of well rotted manure, or of fresh soil applied over its roots; and trees growing on banks can often be benefited by deepening the soil on the lower side. A large body of plant food can thus be supplied without burying any part of the trunk and without injury to the tree.

The internal decay which so many old trees perish, through inability to resist the influence of storms, is caused by dead branches allowed to remain upon the tree or from the stumps of branches left in pruning. It is an almost invariable custom in this country, when a branch is cut from the stem of a tree, to leave a stump a few inches long, as shown in Figure 2. The end of this branch, as it has no lateral shoot to insure a flow of sap, is not healed over with a new formation of wood and bark, and soon dies. Decay thus begins, as appears in Figure 3, and this decay gradually extends into the interior of the trunk, as shown in Figure 4, ruining the tree for any useful purpose, and so weakening the supporting power of the stem, that a severe gale will prostrate it. This decay can be prevented by cutting off dead branches as fast as they appear, and by cutting living branches, when it is necessary for any reason to remove them, close to the trunk or close to a lateral branch. The secret of good pruning lies in cutting close, so that the wound may heal by the formation of a new growth over the cut surface. No matter how large it may be necessary to make the wound, no branch stump, large or small, should be left in pruning. A coating of coal-tar applied to the wound as soon as made will serve to protect it from moisture, and will not interfere with the formation of a new layer of wood.

Fig. 3.

Pruning, so far as the trees are concerned, can be done at any time, except in very early spring, when they are gorged with sap and "bleed" more freely than at other seasons of the year. The autumn, however, is found to be the best time for such work. There is more leisure now than earlier in the season, while the coating of ice which often, in this climate, covers the branches of trees in winter, makes it difficult and dangerous to work among them.

Three men at least are needed to prune a large tree properly, and to manage the long, heavy ladders which this operation makes necessary. One man stands at a little distance from the tree and directs where the cuts

shall be made; the second man uses the saw, which must be attached often to a long handle; while the third holds one end of a rope fastened to a belt on the man in the tree, and passed over a branch above his head as a precaution against a fall. Nearly all our forest trees bear severe pruning of this sort, and improve under it. Decrepit Red, Black, White and Swamp Oaks, Black Birches, Beeches, Hickories and Elms have been pruned in this way in the Arnold Arboretum, where many of the trees in the natural woods were perishing from pasturage and neglect. They were covered with dead branches, the foliage upon them was thin and poor, and their dying tops showed that they had but a short time to live. It was important to preserve many of these old trees until a new growth of self-sown seedlings could be brought on to replace them and a covering to the forest floor grown. A portion of these old trees are pruned each year, and those which were operated upon first, or six or seven years ago, show, in their dense, dark-colored foliage, compact habit and vigorous growth, how pruning can, without fresh soil and without the aid of manure, put new life into feeble and dying trees.

Fig. 4.

It often happens that when trees have grown together thickly, as in a forest, they are destitute of lower branches. When such trees are thinned, as often happens in the improvement of grounds, single specimens are left with long, straight stems, and without foliage except at the very top. Such trees, from the point of view of ornamental gardening, are ugly objects, and are, moreover, liable to blow down in the first gale.

But there is no deciduous tree, however tall and unsightly it may be, which cannot be gradually converted into a handsome, branching specimen, by the aid of a saw and a pot of coal-tar.

Flowers in Japan.—II.

THE nurseries of the gardeners who supply the Japanese with the immense quantities of flowers, shrubs and trees they demand are scattered about in the suburbs of the cities. They are well kept and contain a great variety of plants, the most valuable of which are usually very old, dwarfed trees. Singular objects, which are greatly prized, are very old trees, which, to all appearances, are quite dead, but still retain sufficient vitality to send forth a few fresh blooming shoots each spring. Good specimens of such trees are not common, and, on several occasions when I found an unusually fine one, I was told by the gardener that it had been in the possession of his family for two or three generations. Rarity, in Japan, as elsewhere, constitutes a virtue, as I found with regard to some of the most highly prized and expensive plants I saw, the chief recommendation of which was by no means their beauty. A small plant, consisting of half a dozen coarse, Pampas-grass-like blades, was pointed out to me by a gardener as one of his most valuable possessions, his price being 300 yen (about \$250). Upon observing my look of astonishment, he assured me that this was not at all an unusual price, and that in former times he might have sold it for double that amount. I was somewhat incredulous, but I learned later, on trustworthy authority, that this was not a fictitious value. These gardeners also arrange flower-shows in their gardens from time to time. One of them, whose place I frequently visited, held an annual Pæony exhibition, which enjoyed more than a local reputation. The potted plants were placed under a light bamboo awning which extended around three sides of the garden. The flowers were placed on step-like shelves, which showed off each plant

distinctly. The exhibition was always announced by the newspapers and was generally largely attended. Over 200 varieties, each represented by the most perfect specimens, were shown. There are also numbers of private gentlemen who devote themselves to horticulture and who give annual exhibitions of their productions.

But the most wonderful and elaborate displays of this kind are given every spring and autumn by the Mikado at his private gardens in Tokio, the former being devoted to a view of the Cherry blossoms and the latter and most attractive to a Chrysanthemum show.

Of late these entertainments have assumed a semi-European character. Four years ago, when I attended one of them, the Empress and her ladies appeared in the picturesque and unique old court dress, but now that has been superseded by the European style, which, as can be imagined, deprives the occasion of much of its former charm and interest.

The entertainment is given in a large park-like garden, where a collection of the most varied and perfect specimens of the Chrysanthemum are on exhibition. A number of light, neatly constructed bamboo sheds are erected, and underneath, on the tiers of shelves, specimen after specimen of every possible variety of this favorite flower is shown in the greatest perfection. These plants, each in a separate pot, bear only two or three flowers each, the others having been nipped in the bud in order to bring the few remaining ones to the greatest development. There are, however, a few exceptions, consisting of plants each of which bears several hundreds of very perfect, though smaller, flowers; and, as the stem of every individual flower is strengthened by means of a fine strip of bamboo and drawn by a thread in a position to show it to the fullest advantage, they seem even more numerous than they are. One of the causes that have tended to make the Chrysanthemum such a favorite, may be the fact that it is the last of the long series of Japanese flowers, and continuing until covered by winter's snow. The Chrysanthemum also forms the Mikado's official crest.

Another exhibition of the Chrysanthemum, consisting of large figures, made up entirely of these flowers, of different colors, is very popular with the masses. Several months in advance of the Chrysanthemum season the frame-work of great figures, ranging from life-size to thirty feet in height, is constructed of wood and bamboo. Over this frame-work is a covering of rough wicker-work which outlines the forms of the figures. The head, hands and feet are made of *papier maché*, colored like life. The wicker-work interior is then filled in with great quantities of Chrysanthemum plants in bud. If, for instance, one of these figures is to be represented in a white garment, then the whole surface of the figure is filled in with white flowers. If embroidery is to figure thereupon, the effect is produced by variously colored flowers—yellow to represent gold, etc.—and as the embroidery generally consists of floral designs, it is readily produced by flowers of the shade required. The plants are placed inside of the wicker-work covering, with the thickly massed buds protruding, while the roots are inside. The interior space is then filled with earth, and when the solid masses of blossoms burst into bloom, they form a most harmonious glow of color, and so skillfully are they arranged, that the effect, at the proper distance, is quite deceptive, and gives one a very fair representation of richly embroidered costumes.

These figures are arranged singly and in groups, and represent, as a rule, mythological and historical characters. A favorite among these characters is the great hero, General Benke, in the act of slaying an enormous dragon. Another represents a fair courtesan in rich attire, accompanied by her little maid, who stops and gazes with consternation at an old priest who slowly approaches, and prophetically holds a grinning skull before her. A junk of almost natural size, with life-size figures, generally forms one of the most elaborate representations. Wrestlers

in life-like action, solemn gods and goddesses, without number, are here presented in floral attire, to the admiring multitude who flock in thousands to the spot.

New York.

Theodore Wores.

A Woodland Tragedy.

TO the conscientiously scientific student of Nature everything that grows may possibly be of equal interest at all times. But I think that for all desultory observers like myself there is sure, from week to week, to be some new thing which, at the moment, specially touches the fancy and seems more interesting than everything besides. A while ago I was all for the Heaths. Any one of their kindred seemed enchanting, and nothing else seemed half so much so. Just now the Sundews have taken their place in my affections. *Drosera rotundifolia* is our common species. This, of course, is one of the things that must be looked for; but if one looks it appears in a hundred spots, each of more fairy-like loveliness than the other. Tiny islets of moss set around with low Blueberry bushes in half-swampy meadows are its favorite stations, where it forms little clumps of half a dozen plants. But I have found one spot where it grows in much greater profusion. Far back from the high-roads, through a wide-spreading growth of young trees and thickly intermingled shrubs—a growth too young as yet to be called a forest—runs an abandoned road, green now over all its length, and often to be traced only by the fact that it lies a little lower than the general surface of the ground. Along this road, at a place which is swampy after rain but dry enough in time of drought, the moss is tangled with Cranberry vines and spotted with patches of Sundews, while if one stoops and lifts the curtain of shrubs and creepers which overhangs the little foot-high embankment on either side, its face is found to be clothed for yards with the round, red, bristly little leaves, each tiny hair bearing its drop of glue, like a diamond awaiting some Titania's ear. Of course the fact that these miniature, jewel-like arrangements are murderous arrangements is what makes them so attractive. Modest and retiring though it is, this tiny plant gives us a chance to see a bit of the great world-drama called the struggle for life in vivid action. Although we know that one plant always lives by the death of another, we do not often see this truth in clearly visible shape. When we do, as when a Dodder is sucking the life out of some tender stem, we suddenly find our interest in vegetable development intensified; and when it is not a plant but an animal that succumbs, the interest grows positively tragic in strength. We may poison or catch flies by hundreds in our rooms and never think of such words as fate or the struggle for existence—the forces in conflict are too unequal. But watch a little, lovely Sundew leaf when a tiny fly alights upon it, sit patiently for some thirty minutes until the insect disappears in a tight, little, red, clammy fist, and the whole panorama of the world's history seems to unroll before the imagination. Perhaps it is because here the usual results are reversed, and, animal and vegetable forces coming in conflict, the weaker-seeming prevail; perhaps it is simply because we seldom think of plants as acting at all, and suddenly find them in what looks like conscious effort; but, whatever the reason, it must be a dull mind that is not thrilled with a sense of the interdependence of all created things, of the awfulness of Nature's methods, the irresistible force of fate, the iron rule of the law that nothing can live but by the death of something else, when he sees a Sundew clasp its victim. Do such words sound too big for so small a drama—for a catastrophe which can be hidden by the curl of a Fern-tip or the fall of a Blueberry leaf? If so, it is because you have never looked long enough at tiny things to realize that what we call size counts for nothing in Nature's mind, whether beauty or significance be her aim, and have never, while realizing this, seen a Sundew catch a fly.

M. G. van Rensselaer.

Marion, Mass.

Foreign Correspondence.

London Letter.

THE trial plots in the gardens of the Royal Horticultural Society at Chiswick, a few miles from the centre of London, are now full of interest to gardeners and all interested in fruits, flowers or vegetables. For years the Society has made trial of important flowers, fruits and vegetables in order to test their qualities. They invite the principal nurserymen and seedsmen to send collections of particular classes, including their novelties, and all are grown under as suitable conditions as is possible, so that a fair test is given to all, and as the garden of the Society is neutral ground, the trials have much value both to tradesmen and to the gardening public. The subjects vary from year to year. Sometimes it is Peas among vegetables; Strawberries among fruits; Pelargoniums or Begonias among flowers, the subjects being chosen according to their importance, their popularity or the state of the nomenclature of their varieties. By these means one is able to see and inspect in a small area a collection of many varieties, and in this way comparison of qualities can be easily made. These public trials also furnish a check upon the nomenclature, especially in reducing synonymy. For instance, last season, Tomatoes were put under trial. There was a multitude of named varieties, but at judging-time the Committee found so many identical that the number of distinct kinds was very small. This is good work, as it enables the amateur to select the best and shun the worthless sorts.

Among the subjects under trial this year in the way of flowers are China Asters, Ten-week Stocks and bedding Lobelias, and I have to-day been included in the Committee whose work it is to judge these. We found an enormous array of China Asters and Stocks, probably a hundred named sorts, all growing side by side in lines precisely under the same conditions, raised at the same time and planted out simultaneously, and all received the same cultural treatment. The principal exhibitors were, of course, continental firms, as we do not in England save our own China Aster or Stock seeds. Messrs. Vilmorin-Andrieux & Co., of Paris, and Messrs. Benary, of Erfurt, sent most of the seeds for trial, the collections of both being admirable, and it was difficult to say which was best. One who had never seen great collections of these flowers would be astonished at the great diversity of stature, of habit and of color among them. The practice of the Committee is to denote the qualities of the subjects by marks. Thus, one mark is given for good habit of growth, one for form of flower, one for richness, distinctness of color, and so on; but, as a rule, only those sorts that can command three points—that is, are good in habit, in flower and in color—are considered, and the three marks are taken as equivalent to a first-class certificate.

The Ten-week Stocks were a difficult class to judge, as there is such a difference in habit and color among them. I will not attempt to enumerate all the varieties which were counted worthy of a triple distinction, but will select a few. The best of all were comprised in the tall, large-flowered section. The spikes of bloom are massive, and the flowers perfect rosettes, while for profusion of bloom and compactness of growth they are faultless. The selected sorts were blood-red, sulphur-yellow, lilac, violet, light violet and purple, all of which were sent by Vilmorin. Benary's collection contained some very charming colors, and what pleased me most were the subtle half tones, which, I fear, many, who like only distinct and bright colors, would not admit into gardens. One called Ash-gray was a peculiar shade of grayish purple, quite indescribable; another called Chamois was a soft fawn tint, and others called Lilac Rose and Mauve Purple are most beautiful. The difficulty is to find names for them all. The attempt to describe the colors by the names is often a failure, while to give fancy names to each would be absurd and lead to confusion. Some of the dwarf sorts were exceptionally fine, the plants

being not more than six inches high and complete masses of bloom, and one double white variety was singled out as the best of all the dwarfs. The Wallflower, cleaved section, which have shining, not hoary, leaves (as in ordinary Stocks), are a failure as far as this trial is concerned, and so is what is called the Dwarf Bouquet section. They are not to be compared with the tall and dwarf double-flowered sorts.

Among the China Asters we found only a few that were in a fit condition to judge, the plants not being in full bloom. But these very early kinds in full bloom just now are of great value, as they prolong the China Aster season, and what we want is a very late strain which would extend the season over six or eight weeks. The dwarf strains are very popular, as they are compact in growth and extremely floriferous. A few uncommonly fine ones received to-day the full number of marks. Among these in the Dwarf Chrysanthemum section were: Crimson, Scarlet Red, Rose and White, all with large, full flowers, abundantly produced on plants about nine inches high. There is also a strain called the Dwarf Queen, ranging through crimson, carmine rose, purple and white. But the most beautiful Asters, in my opinion, are yet to bloom, and we shall inspect these a fortnight hence. These comprise the Pæony-flowered, Tall Chrysanthemum-flowered, Victoria, Pyramidal, Quilled Pompone and Cockade sections. These China Asters seem to become more popular every year since such fine strains have been obtained. They are capable of producing very beautiful effects in the flower-border and require the simplest culture. The present moist season has suited them well, as they have seldom been finer at Chiswick.

No advance whatever seems to have been made lately in improving the bedding Lobelias, as the varieties on trial, including novelties, do not show any improvement over the old strains.

A collection of Tomatoes is again on trial and a wonderful display of fruiting plants is to be seen. The principal house (100 feet by 30 wide) is crowded with plants in beds and trained to upright stakes. They range from six feet to ten feet high and are profusely hung with fruits, though only to-day 200 pounds had been cut. Of the almost countless varieties two stand out prominently as the finest of the collection. One is called Horsford's Prelude, an American variety, having been sent by Messrs. Horsford & Pringle, of Vermont. It is a wonderfully productive sort, the fruit numbering as many as a dozen or more in a cluster, hanging at regular intervals all up the stem. The fruit is of medium size, smooth, bright red, very succulent and of good flavor. It is pronounced first-class, and is likely to supersede all others, especially for the market. The other favorite sort is Perfection, known under numerous aliases, for it is so good that every firm seemed anxious to call it their own Perfection. It is a very large sort, with perfectly smooth fruits, very fleshy and well flavored. It is showy, and therefore gains a point upon Prelude, though it is not so productive. The value, however, of such a fine fruited sort, is that the fruits fetch fully a penny a pound more in the market than the small kinds, like Prelude, which sells at the moment at six, while Perfection sells at seven pence per pound. A prolific sort is President Garfield, called also King Humbert and Chiswick Red, but it is nowhere, now that Prelude is in the field. All credit is due to the American seedsmen for sending us such a valuable fruit.

London, August 24th, 1888.

W. Goldring.

New or Little Known Plants.

Pseudophœnix Sargentii.

ON the 19th of April, 1886, in company with Mr. C. E. Faxon, Mr. A. H. Curtiss, and Lieut. Hubbard, of the United States Navy, I landed from the Light-house Tender "Laurel" near the eastern end of Elliott's Key, one of the

larger of the Florida Reef Keys, at the house and Pineapple plantation of Mr. Henry Filer. Our attention was at once directed to a solitary plant of a small pinnate-leaved Palm, left standing in the clearing, which, at first sight, was mistaken for an *Oreodoxa*, but the large orange-scarlet fruit at once showed that we had stumbled upon a tree unknown before in the North American Flora, and quite unlike any of the species of Palms known to us. Specimens of the fruit, which was not, unfortunately, fully ripe, were sent to Dr. Wendland, of Hanover, who provisionally pronounced our Palm to be the representative of a new genus, for which he proposed the name of *Pseudophœnix*. A short account of this discovery, with the announcement of Dr. Wendland's new genus, but without characters, was published in the issue of the *Botanical Gazette*, for November, 1886, but it was not until a year later that I received through Mr. Curtiss ripe seed of the *Pseudophœnix*, which was sent to Dr. Wendland, who has drawn up from it generic characters.*

Pseudophœnix Sargentii is a slender, low tree, twenty to twenty-five feet high, with a trunk ten to twelve inches in diameter, and abruptly pinnate leaves four or five feet long, the pinnæ lanceolate-acuminate, twelve to sixteen inches long, bright green above and glaucous on the lower surface. The branching spadix appears from among the leaves; it is (in the only specimen seen by me) thirty-six inches long by thirty inches broad, the main and secondary branches light yellow-green, flattened, and the latter thickened at the base, especially on the upper side, into an ear-like process. The three-lobed fruit, often one or two-lobed by abortion, is a half to three-quarters of an inch in diameter, bright orange-scarlet, and very showy. Only the withered remnants of the flowers have been collected.

A few individuals were discovered scattered through the woods in the neighborhood of Mr. Filer's plantation, and, late in the same year, a grove of them was discovered near the east end of Long's Key by a gentleman from Bay Biscayne whose name I cannot recall. There are about 200 plants, large and small, in this grove, which is represented in the illustration upon page 353, from a photograph made by Mr. James M. Codman at the time of our visit to Long's Key in the spring of 1887. These are the only stations where *Pseudophœnix* is now known, but as the flora of the Florida Reef Keys is Bahaman in its constitution, and probably in its origin, it would be a singular fact if this tree was not found in some of the Bahama group, the plants of which are still very imperfectly known.

The figure of the fruit (see page 355) is engraved from a drawing made by Mr. Faxon.

C. S. S.

Cultural Department.

Cultivation of Native Ferns.—IV.

Aspidium Goldianum.—As Eaton says, "This is one of the very finest and largest species of the Eastern States." In even choice collections this species will always be one of the prides of the owner on account of the size, color and beauty of the fronds and comparative rarity of the species. Its early summer growth is tipped and bordered with vivid golden green. The mature frond takes on a deep, rich green of much beauty. Rich soil. Two and a half to four feet. Fronds on one fine specimen measure four feet two and a half inches.

Aspidium Filix-mas.—A strong, fine-growing, half-ever-green species of great beauty. Under high cultivation this produces splendid masses of fronds. Thirty to forty inches.

Aspidium marginale.—An attractive common species. The half-evergreen fronds grow in a handsome vase form. Grows finely in rich soil; but will grow in extremely poor and dry situations. Eighteen to twenty-nine inches.

* *Pseudophœnix* Nov. Gen., Herm. Wendl. Gaussire affinis.

Fructus stipitatus drupaceus cerasiformis aurantiacus, e carpellis 1-3 globosis stigmatum residuis basilariibus vel in fructibus lobatis lateraliibus vel centralibus, epicarpio coriaceo, mesocarpio grumoso, endocarpio tenuiter vitreo-crustaceo. Semen liberum subglobosum erectum, hilo basilari, raphe ascendente utrinque ramis 2-3 manifestis curvatis, albumine æquabili: embryo basilari.

Fl. fem. in fructu: calyx parvus pateriformis leviter 3-denticulatus. Petala 3 ovata obtusa, viridia refracta. Staminodia 6 manifesta apice atropurpureo.

— Palma mediocris, erecta, foliis pinnatisectis, segmentis duriusculis ima basi valde repliatis.

Species 1. *P. Sargentii*, Herm. Wendl. Elliott's Key, Florida.

Aspidium spinulosum.—This common and handsome sub-evergreen Fern is one of the mainstays of the Fern garden. In good soil well established plants send up abundant fronds to a good height from the stout root-stock. Of easiest possible culture, growing finely even in poor and dry soil. Two to two and a half feet. The varieties *intermedium* and *dilatatum* are both as desirable as the type. A fine plant of the latter variety measures thirty-seven inches in height.

Aspidium Boottii.—Very close to *A. spinulosum*. Remarks and culture the same as for that species. Two and a half feet.

Aspidium fragrans.—This rare Fern is difficult to cultivate; one can hardly expect to grow it more than a few years. Evergreen. Plant in rather dry, well-drained clefts in rocks, and cover with a frame in winter, or plant in pots wedged in with stones. Peat and leaf-mould. *Four to ten inches*.

Aspidium aculeatum, var. *Braunii*.—This rare and beautiful sub-evergreen Fern is one of the choicest of our natives for cultivation. Fronds deep, rich green and chaffy; very distinct, easily grown. Fifteen to nineteen inches. The type of this species and the closely related *Aspidium angulare*, natives of Europe, are both very handsome and desirable Ferns to cultivate. They do well with a frame protection in winter, and may be perfectly hardy, as is our variety.

Cystopteris fragilis.—A very charming little Fern of easy culture. Will thrive under very various conditions of moisture or sunshine. Nine to twelve and a half inches.

Cystopteris bulbifera.—This, when well grown, is one of the most beautiful and interesting of our native Ferns. It wants a moist, cool spot, and then will develop fronds of surpassing grace and beauty. It increases very rapidly by bulblets,

Fig. 55.—*Pseudophoenix Sargentii* on Long's Key, Florida.—See page

Aspidium Lonchitis.—This handsome evergreen Fern is, unfortunately, difficult to grow. Peat and leaf-mould. A native of the far north and north-west. Frame. *Six to eighteen inches*.

Aspidium acrostichoides.—A very fine Fern in cultivation, its thick, glossy, rich evergreen foliage being fine by itself, or as a contrast with lighter green species. The variety *Incisum* is very handsome, deeply cleft individuals being almost suggestive of Holly leaves. The fronds of this species are used by the trade extensively in winter in making up bouquets, and it might, therefore, pay to grow it commercially. Eighteen to twenty-two inches.

Aspidium munitum.—A handsome evergreen species from the north-west, well worth cultivating. Not hardy; but at the Botanic Garden in Cambridge it does well with a frame in winter. Fifteen to eighteen inches.

which fall to the ground and root freely. The bed should be thinned out and the plants reset occasionally to get the best results. It is very fine grown at a little elevation, as on a moist bank or portion of the rock-work; the graceful fronds can then show off to greatest advantage. Twenty-four to thirty inches.

Onoclea sensibilis.—This Fern is very desirable on account of its distinctness and possibilities under cultivation. It might be overlooked by a cultivator on account of its commonness; but it would be a great mistake to omit it from the Fern-garden. The broad, light green frond is an object of great beauty, intermingled with darker species, and with good culture attains fine proportions. Two and a half to three and a half feet.

Onoclea Struthiopteris.—This splendid Fern is capable of producing very grand, almost sub-tropical effects, when well

grown, and in quantity, or as a single specimen plant, forms a striking object in the Fern-garden. In spring the pinnæ of the young fronds overlap one another in a graceful fashion, suggestive of the form seen in well curled ostrich plumes. Gradually the fronds push up until they attain a height of four feet or more in fine specimens, and spreading out in a vase-like form from the abbreviated, tree-like base, make truly splendid Fern effects. The brown fertile fronds come up in midsummer and give a pleasing contrast to the green, sterile fronds. It increases rapidly by sucker-like, running root-stocks. These should be dug up occasionally and planted elsewhere, or otherwise disposed of, as they will interfere with the main plants if allowed to remain. Four to four and one-half feet.

Woodsia glabella and *W. hyperborea* are delicate little Ferns, growing naturally in shaded clefts of rocks trickling with moisture. They would be both difficult to cultivate, and had, perhaps, best be attempted in a Wardian case in a very cool green-house. Only *W. hyperborea* has been grown by me or seen under cultivation. *W. glabella*. One to four inches; *W. hyperborea*. Two to six inches.

Woodsia ilvensis.—Grows in dense clumps of extremely pretty chaffy fronds. When young the fronds are almost silvery from a thick coating of chaff. Plant in well-drained, sunny spots, with rocks. Very attractive in cultivation. Two to five inches.

Woodsia obtusa.—A very pretty Fern, not difficult to grow. Peat and leaf-mould. A plant at the Botanical Garden in Cambridge measures ten inches.

Dicksonia pilosiuscula.—A handsome, desirable species. Fronds quite tall, light green, sweet scented. A fine Fern for covering bare spots with a dense, carpet-like growth. Grows freely in any situation. Two and one-half to three feet.

Lygodium palmatum.—This, the Hartford trailing Fern, is one of the most striking and attractive of all our native species. Rather difficult to get established, but, judging from a fine clump in Dr. Henry P. Walcott's garden in Cambridge, it does well after it is established.* Two feet, growing taller as the season advances.

Osmunda regalis.—A fine Fern, very distinct from the two following species. In spring the fronds come up, of an exquisite reddish brown, passing into green, and the brown stems are covered with a bloom. The color and form and grace of the young fronds have an indescribable charm. Later the fronds push up till they reach a size entitling this Fern to highest rank amongst the showy native species. The popular name of Royal Fern was given to this species in England, where it attains a much greater size than in this country. Moore, in "The Ferns of Great Britain and Ireland," says it attains the height of six to eight or even ten to twelve feet in damp, sheltered situations. A splendid specimen, seen growing in an artificial bog at Kew Gardens, towered above the head of a tall man. In cultivating this fine Fern, as well as the two other species of the genus, secure the largest roots possible and plant in the dampest spot in the garden; a natural or artificial bog will be found best adapted for their needs. The specimens measured are grown in ordinary garden soil; but even then good results may be obtained. Three to three and one-half feet.

Osmunda Claytoniana.—The sterile fronds of this species are quite similar to those of *O. cinnamomea*, but the fertile are combined in a single frond, with a sterile portion unlike that species. It is a very handsome Fern, particularly when in fruit. Culture the same as for *O. regalis*. Forty to forty-six inches.

Osmunda cinnamomea.—One of the finest and most distinct of our native Ferns. The delightful woolly fronds come up in spring strong and vigorous, with a beauty peculiarly their own. In early summer the fertile or flowering fronds, as they are called, form a fine cluster of cinnamon-brown spikes in the centre of the vase, forming tall, green fronds, producing a very fine effect. In autumn the fronds commonly change to a rich reddish or golden yellow. Culture as for *O. regalis*.† Three to three and one-half feet. These measurements could doubtless be much exceeded under favorable circumstances.

The Botrychiums are a difficult group to handle, and I have never seen them successfully established under cultivation.

*The species is considered as indigenous only to the United States; but, curiously, Dr. Walcott's plant was sent to him from Europe, and was said to have come from Japan.

†*O. cinnamomea* is the only Fern, as far as observed, that seems to be truly affected by cultivation. The lower divisions of the pinnæ in several plants in the writer's collection are produced and are themselves pinnatifid. Eaton notes this as occurring sometimes in luxuriant wild specimens. The character varies in degree or may be wanting in different seasons on the same plant. A plant of the variety frondosa also varies in different seasons and individual fronds in showing its varietal characteristic.

tion. For a year they will grow well, and sometimes two or three years they survive; but they eventually become smaller and smaller and soon disappear. Many plants known to the horticulturist will not bear transplanting, and this may be such a case, so that if grown from spores where they were to remain, Botrychiums might be successfully cultivated. *Botrychium Virginianum* is the strongest and tallest of our species, and Mr. Robinson says it is the easiest to cultivate; it would, therefore, probably be the best species to attempt to grow by means of spores. Leaf-mould and peat. Eight to twenty-four inches. Mrs. P. D. Richards, of West Medford, has grown *Botrychium ternatum*, var. *dissectum*, in pots successfully for a limited period. There are four other species of Botrychiums indigenous to New England, but they are omitted, as no cultural remarks can be made concerning them.

Ophioglossum vulgatum.—This Fern, like the Botrychiums, may be considered difficult to cultivate. It may be grown for a short time in pots in peat and leaf-mould, and perhaps, with similar treatment, in the open ground. Two to twelve inches.

In the following lists the Ferns not indigenous to New England are designated by an asterisk, and an interrogation mark signifies that a Fern questionably belongs to a list, and that it may more properly be considered under one of the other lists.

Perfectly hardy Ferns, easily grown and desirable for general cultivation:

<i>Polypodium vulgare.</i>	<i>Aspidium spinulosum</i> and varieties.
<i>Pteris aquilina.</i>	" <i>Bootii.</i>
<i>Adiantum pedatum.</i>	" <i>acrostichoides.</i>
<i>Asplenium ebeneum?</i>	" " var.
" <i>angustifolium.</i>	" <i>incisum.</i>
" <i>Thelypteroides.</i>	" <i>aculeatum,</i> var.
" <i>Filix-femina</i> and varieties.	" <i>Braunii.</i>
<i>Phegopteris polypodioides.</i>	<i>Cystopteris fragilis.</i>
" <i>hexagonoptera?</i>	" <i>bulbifera.</i>
" <i>Dryopteris.</i>	<i>Onoclea sensibilis.</i>
<i>Aspidium Noveboracense.</i>	" <i>Struthiopteris.</i>
" <i>Thelypteris.</i>	<i>Woodsia ilvensis.</i>
" <i>cristatum.</i>	" <i>obtusa.</i>
" " var. <i>Clin-</i>	<i>Dicksonia pilosiuscula.</i>
" <i>tonianum.</i>	<i>Lygodium palmatum?</i>
" <i>Goldianum.</i>	<i>Osmunda regalis.</i>
" <i>Filix-mas.</i>	" <i>Claytoniana.</i>
" <i>marginale.</i>	" <i>cinnamomea.</i>

Ferns requiring the protection of a frame in winter, but easily grown with that care:

* <i>Polypodium Californicum.</i>	<i>Camptosorus rhizophyllus.</i>
* <i>Lomaria Spicant.</i>	<i>Phegopteris hexagonoptera.</i>
<i>Asplenium Trichomanes.</i>	* " <i>calcareo.</i>
" <i>ebeneum.</i>	* <i>Aspidium Nevadense.</i>
* <i>Scolopendrium vulgare.</i>	* " <i>munitum.</i>

Ferns more or less difficult to cultivate, and best grown in pots, or with the protection of a frame in winter:

<i>Pellaea gracilis.</i>	<i>Camptosorus rhizophyllus.</i>
" <i>atropurpurea.</i>	<i>Aspidium fragrans.</i>
<i>Cryptogramme acrostichoides.</i>	* " <i>Louchitis.</i>
<i>Woodwardia angustifolia.</i>	<i>Woodsia glabella.</i>
" <i>Virginica.</i>	" <i>hyperborea.</i>
<i>Asplenium viride.</i>	<i>Botrychium.</i>
" <i>Ruta-muraria.</i>	<i>Ophioglossum vulgatum.</i>

Boston.

Robert T. Jackson.

Dutch Bulbs.

HYACINTHS, Tulips, Crocus, Narcissus and the like now claim attention. Complaints are often made that these bulbs do not succeed; they either winter-kill or fail to produce such flowers as the catalogues promise, or such even as are seen when the bulbs are grown in pots, and every year comes the repeated question, "Why did we fail?" For the failure there may be many causes, and the first is the neglect to plant the bulbs at the proper season. While these bulbs all require perfect rest, when they may be kept as dry as seeds, it does not follow that they can remain out of ground beyond a given time without injury. For the best success all Dutch bulbs should be planted by the first of October, and, if worth planting at all, it should not be deferred until November, because by that time they commence growth, and when this goes on in their dry state their vitality is impaired.

The next cause of failure, and the most important of all, is

the general impression that these bulbs are hardy. Hyacinths, Narcissus and many other Dutch bulbs are not hardy, and are not so considered by those who cultivate them for sale. In Holland the beds are mulched with the reed, so common on the borders of their canals, so that it is impossible for the frost to penetrate the earth at all. This precaution is needed in this country more than in Holland, because of the constant and severe changes of temperature. Our experience has taught us the necessity of mulching so thoroughly that frost cannot even enter the ground, much less reach the bulbs. With this precaution we can grow the Hyacinth as successfully as the celebrated Dutch growers, although we have more, in the way of climatic changes, to contend with, than they.

A great difficulty is the marked change in temperature so common in April or May, when the flowers appear. Some suitable covering for the bed should be at hand, ready for use when required, and thrown over the plants when there is danger of a severe frost.

The best mulching we have ever tried, and the most natural one, is newly fallen leaves, always abundant in the garden; cover the bed to the depth of a foot, and keep the leaves from getting scattered about by a layer of evergreen boughs; if these are not convenient, use brush of any kind or old boards; whatever is the easiest to obtain is the best to use.

The Polyanthus Narcissus is still less hardy, in fact it will not endure freezing, and therefore must be carefully protected.

Tulips are hardy, but they will produce far finer blooms if moderately protected, and the same may be said of Crocus.

without division, giving annually fine spikes of bloom. The cost of second-sized bulbs is considerably less than larger ones, and that, too, is a point in their favor.

As a spring flower for garden decoration nothing can surpass the Tulip. The finest varieties of these bulbs can now be obtained at prices that will permit their general cultivation, and with a little care they will rapidly increase. The Tulip delights in the same soil as the Hyacinth, and it should be prepared in the same manner. The bulbs should be placed four or five inches below the surface, according to size, and it is important that each variety should be put in at a uniform depth to insure simultaneous display. Tulips will do well planted any time before the ground freezes up. They do better by far if planted much earlier—in fact, as early as they can be obtained.

The hardy varieties of Narcissus, now very popular, should be planted in quantity, especially in those spots where it appears naturally at home, such as under the shade of trees and in shrubby borders. There is now an awakened interest in the many forms of double and single Narcissus (Daffodils), and they are certainly most effective garden flowers. All the varieties should be grown in clumps and patches in every spot which is suitable and vacant. In any out-of-the-way place large quantities of *N. poeticus* should be planted for a supply of cut flowers. Their graceful appearance renders them peculiarly valuable for this purpose, and if cut when partially opened, they will develop in water and last for many days. In planting be guided by the size of the bulb, allowing four or five inches between small sorts, and five or six inches between the larger varieties. Bulbs of Narcissus may remain undisturbed for many years, and annually improve in the quantity and quality of the bloom. Soil is a secondary matter with the Narcissus; a moderately heavy one is to be preferred, but they will grow almost anywhere.

The Crocus must be planted early to succeed. If kept out of the ground until November it will never regain its lost vitality. Plant in September if possible, and in no case after October. These bulbs will grow in any soil, and do fairly well for many years undisturbed. Make the soil very rich, cover the bulbs two inches, and protect the same as Hyacinths.

Snowdrops are about the earliest spring flowers, and particularly desirable because of their willingness to bloom under all circumstances. It seriously injures these bulbs to remain long out of ground; therefore plant early, about two inches deep, and, if possible, where they may remain undisturbed for many years. In moist, shaded places they will form dense masses, completely driving out all other herbaceous vegetation.

Crown Imperials can only be grown to advantage in gardens, and stately plants they are. They demand a rich, light soil and an open position. Carefully protect against frost, for although frost hardly injures the growing plant, the bulbs are always injured by freezing.

C. L. Allen.

Queens, N. Y.

Fig. 56.—Fruit of *Pseudophœnix Sargentii*.—See page 352.

a—Portion of a panicle (natural size).
 b—Section of a Fruit.
 c—Seed, showing raphis.
 d—Embryo.

The most suitable soil for Hyacinths is a light, rich, sandy loam or clear sand; but they will do well in any good garden soil. To grow them to perfection, however, special treatment is necessary, and no plants require more care to keep them from degenerating than the Hyacinth. They are strong feeders, and the soil cannot very well be too rich, if they are to produce strong spikes of flowers. No fresh or rank manure, however, should be used on any account. Thoroughly rotted manure from the cow-stable is the best, and it should be placed a foot below the surface of the bed.

In making beds for Hyacinths the ground should be dug to the depth of at least fifteen inches, and proper provision should be made for effectual drainage. Six inches of manure should be placed at the bottom and covered with four inches of soil; upon this place the bulbs, say five inches apart each way. If the soil is heavy and tenacious, cover the bulbs with a little coarse sand, then cover the whole with soil so that the crowns will be at least five inches below the surface. Hyacinths can be grown fairly well without this care, but perfection of bloom, for which every cultivator should strive, requires all the care here recommended.

The selection of the bulbs is, to a considerable extent, one of individual taste as regards colors and variety of form, but a few rules can be laid down for general use. Choose the heaviest and most solid. Size is not of so much importance, except for forcing in pots or glasses, when the largest and best should be chosen. For the open border, medium or small bulbs are preferable, as they will remain longer in the ground

The Vegetable Garden.

OLD plants of Globe Artichoke now show many dead leaves and flower stems, which should be cut and removed. Have the frames, sashes or other protectors ready to place over the Snap Beans, Cucumbers and Tomatoes, to save them from frost. If Brussels Sprouts show no tendency to sprout pinch the points out of a row of them; this will induce them to form side sprouts early, but these early sprouts are not likely to be solid; only those that appear naturally can be depended on. If Cabbages or Cauliflowers are hearting too soon, pry up the plants a little with a digging fork, then pack the ground solid about them again; this checks their growth. Keep young Carrots, Beets and Turnips thoroughly clean, and hoe them every week. Sow a little Chervil for use in spring, and, if desired for winter, sow some in a frame. Sow some Corn Salad in a frame in rows six inches apart. As this is a small growing vegetable it should be sown thickly. German Greens can be sowed in rows, fifteen inches apart, in rich but well-drained ground out-of-doors, for use in spring. This crop should be lightly mulched with sedge, sea thatch or dry leaves in winter. Erfurt Cauliflower and Wakefield Cabbages were formerly sowed about the 20th of September to be wintered in cold-frames and planted out for early spring crop, but we are more successful with plants raised in the greenhouse or hot-bed in February or the 1st of March. But in the Southern States fall sowing is still much practiced. Early Celery should be earthed up as required, but banking the late winter crops should be delayed. Never handle Celery while it is wet with dew or rain. Put in a large sowing of Lettuces for winter use. Sow them out-of-doors and early in October prick them closely into a cold-frame. Salamander is the best

for use before Christmas; after that, Boston Market; but both must be sown now. Lettuces planted out in the open garden after this time of year will not be likely to mature before frost destroys them, but, if planted now, the half-grown Lettuces can be lifted into the frames in October. It is from the frames thus filled that our supply of young plants is drawn for hot-beds between November and February.

Winter Spinach should be sown now. If it is to be left uncovered over winter, sow the Prickly-seeded; if it is to be protected by frames or mulching, the Round-seeded will be just as good and rather more prolific. The soil should be rich, and have a warm, sunny aspect, sheltered from cold winds, and so well drained that water cannot lie upon it in winter. If in the open garden the rows may be fifteen inches apart. The ground set apart for Winter Spinach has been occupied during the summer by green-house, winter-flowering plants, which we are now lifting and potting. Last year we used ground that had been cropped with early Melons. Field mice are so numerous and destructive here, that it is useless to try Spinach in the open ground and mulch it in winter; we cover our crop with cold-frames. The land is marked off in strips eight and one-half feet wide; this gives strips six feet wide for the frames, with two and one-half feet for passages between them. Seven rows, ten inches apart, running lengthwise, are then marked off to each string of frames, and this leaves a few inches between the outer rows and the sides of the frames. The frames may be laid down now or in November, but must not be covered with sashes till sharp frost occurs. Spinach sown now will yield a good picking in about five or six weeks after sowing, but, except to thin it where it is too thick, it should not be picked clean. During the winter months there is no need to exclude frost altogether; sashes, straw mats and extra sashes or shutters over the mats in the case of very severe weather, will answer, if in early December the frames are banked with earth, leaves or manure.

Onion sets are often planted in fall so as to save time in spring. This should be done early, so as to get them well started before winter sets in. Use light, warm, dry soil, and plant in rows marked off four inches deep and a foot apart. Yellow Danvers, Red Wethersfield and Southport White Globe are good Onions for this crop. To insure a good crop, these Onions should be mulched in winter to prevent "scalding" and frost heading, so, taking all things into consideration, it is better not to plant out any in the fall, but wait till early spring. Many gardeners sow a bed of Danvers Onions early in September and mulch it in winter, to supply green Onions early in spring.

Glen Cove, L. I.

Wm. Falconer.

Fay's Prolific Currant.—The commendation of this Currant by Mr. Williams, in the issue of GARDEN AND FOREST for August 8th, is none too emphatic. In my experience with the newer small fruits, I find it is the one which meets all the claims made for it by its originator and propagator. And, by the way, is Mr. Josselyn, its propagator, a descendant of the Josselyn who, in 1672, published "New England Varieties of Red and Black Currants"?

About six years ago I purchased a single plant of Fay's Currant for one dollar, and, in my ground, it has justified all the promises made, and wherever I have seen it growing in New Jersey it has been far ahead of the Cherry or Versailles in production, while in size and quality it is their equal, to say the least.

I have a dozen bushes propagated from the original one, and this year have picked eighty-four quarts, or an average of seven quarts to each plant, the bunches of fruit being from four to five inches long, while many measured fully six inches. The space between the base of the stem and the first berry greatly facilitates the work of picking and saves the fruit from being crushed. The Cherry and Versailles set their fruit close up to the old wood, and in a compact mass, which makes picking difficult.

In size I find Fay's as large as the Cherry or Versailles in their best condition, more full of juice and of superior quality.

I never found a Currant so satisfactory for jelly and table use, and, if picked at the right time, it makes more jelly and in less time than any other variety. In fact, I have discarded all others. It may be doubted whether any expert, with his eyes shut, could distinguish the flavor of Fay's and the Cherry at their best, while in appearance Fay's far excels all others.

With berries half an inch in diameter, and bunches from four to five inches long, and the bushes literally loaded, it would seem that perfection in Currants had been reached. But it possesses one more good quality, namely, that all

sound wood grown this year will bear a full crop next year. There are no dormant buds, and, in this respect, it differs from other varieties.

Chas. L. Jones.

Newark, N. J.

China Asters.—Comet maintains its reputation as being one of the most beautiful, large, rose-purple, spreading-petaled varieties. But while each plant produces about a dozen flowers, only a few of them are of full size and perfect. Dwarf White Queen is the best white Aster here. It is small, but not bunched in habit; very free flowering, and the flowers are large, full-double, pure white, and the most of them are large sized. It is earlier than most other varieties, and the plants in the row are of perfectly even size. It seems to be a selection from the Chrysanthemum-flowered section. The New Dwarf Crimson Queen is, except in the color of its flowers, which are purplish-crimson, an exact counterpart of White Queen. Diadem is a new type of Aster, and a novelty of this year. It is a compact-growing, upright, much-branched variety, with small, crimson-purple flowers edged with a band of white. Our plants are now in bloom, and the poorest of any Asters of any type we have. The flowers are very imperfect, and the white band indistinct. After the type has been properly fixed and the band well defined, no doubt this will become a desirable flower. Triumph is one of this year's novelties. It is a dwarf, compact, free-blooming variety, but later in blooming than other China Asters. It is described as "eight or nine inches high." "The flower-heads are from two and a half to three inches across, very perfect in form, with incurved petals of a pure scarlet when first expanded, changing to satiny deep scarlet." Our plants of it are now in bloom, and are about nine inches high, compact, with ten or fifteen medium-sized flowers on each, and these flowers are of a bright purplish-crimson color, and not scarlet at all in any stage of their growth. Did any one ever see a scarlet-flowered China-Aster of any sort?

G. C.

Asclepias atrosanguinea aurea is one of this year's novelties. It is described as a Bolivian species resembling *A. Curassavica* "in habit, but is much more effective; its numerous flowers, borne in large, dense umbels of a deep blood-red, with a golden-yellow corona or centre." This plant and *A. Curassavica* are growing along-side of each other, and are now in bloom. They are both from seed sown in the green-house last spring, and the seedlings planted out in the open garden, where they now are blooming. The flowers of the *A. atrosanguinea aurea* are of a deeper and brighter color (exactly as described above) than those of *A. Curassavica*, but, except in this slight variation in color of blossoms, the two species, so-called, seem to be identical.

F.

Notes from the Arnold Arboretum.

Vitex incisa, which is now in flower, is a small, bushy tree or tall shrub, with erect branches, which are covered with compound, digitate leaves, composed of five to seven lanceolate, deeply pinnatifid leaflets, and terminated with spike-like clusters of handsome blue flowers. The stems are sometimes killed back in severe winters here, but as the flowers are borne on the new growth this does not interfere with the blooming of this really desirable plant. It is a native of northern China, where it seems to be common on mountain-sides. The well known Chaste-tree (*Vitex Agnus-Castus*), a native of the country surrounding the Mediterranean, is not hardy in the Northern States. The other Asiatic species, of which there are two in Japan and a third in northern China, are not in cultivation probably.

Panax sessiliflorum is a native of the Amoor country. It is here a stout and very hardy shrub, with erect, unarmed stems, three or four feet high, and covered with pale brown bark, upon which are many small, darker, wart-like growths. The ample, yellow-green, ternate leaves are borne on long, stout petioles, and quite cover the stems from the ground upward. The flowers are small, with dark purple corolla and stamens, and are aggregated in spherical heads, which are borne on stout stems in short, erect racemes from the axils of the upper leaves. This plant has been in bloom now for more than a month, and it will continue to produce its handsome heads of flowers until the appearance of frost. This peculiarity, the neat, compact habit and great hardiness, make this a desirable garden plant. Its real claim, however, upon the attention of planters, lies in the fact that the flowers are followed by heads of shining black berries, which remain upon the branches bright and fresh until the appearance of the new leaves in spring. The number of shrubs which carry their

fruit fresh through the severe winters of the Northern States is so small, that any addition to the number is welcome.

Clematis Flammula, a native of southern Europe, is a well known garden plant, having been cultivated for three centuries at least. It is a vigorous grower, and its pure white, fragrant flowers are not, perhaps, surpassed in beauty by those of any of the small-flowered, summer-blooming Clematises. A variety of this, a more vigorous and freer-blooming plant, is known in nurseries as *C. Flammula robusta*. It should find a place in every garden in which there is room for a rampant climber capable of covering in the course of a few years a space twenty feet or more square. The stems grow late in the season, and so are often killed back in severe winters; but this pruning only increases the vigor of the plant, and stimulates it to a stronger growth, and more profuse, although a later, blooming. Here the flowers are just opening, and will continue to appear until destroyed by cold weather. Mr. Dawson finds this plant slow and difficult to propagate either by layers or cuttings.

Clematis Pieroti is flowering in the Arboretum for the first time. It is a pretty, delicate Japanese species, with small white flowers and pinnate leaves, the pinnæ sharply and deeply serrate, with prominent veins, covered with short, oppressed hairs, which appear more sparingly on the upper surface. This is an interesting and rather valuable addition to the list of summer flowering, climbing plants, although in habit and in flower it is not unlike our native *C. Virginiana*. It blooms, however, several weeks later. *C. Pieroti* is apparently perfectly hardy.

Cissus Japonica is one of some twenty-five Asiatic, African and Australian species which constitute Planchon's section *Cayratia*, distinguished by the inflated corolla, with spreading petals, devaricately branched cyme, and by the annual stems proceeding from large, tuberous roots, which, in the case of *C. Japonica*, are able to support the climate of our Northern States. The stems are four or five feet high, sharply angled, climbing by means of stout tendrils. The leaves are three to five foliate, long petioled, dark green and lustrous. The sub-axillary cymes of flowers are long peduncled, widely, dichotomously branched. The flowers are short pedicelled, the base of the corolla distinctly swollen, with ovate, triangular, pale rose-colored petals. The fruit, which is hardly as large as a pea, is crimson. This is a widely distributed plant from Japan through many of the East Indian Islands and New Caledonia to tropical Australia. It has little value as an ornamental garden-plant, but much interest as representing a curious form of the Grape Vine.

7.

The Forest.

A New Forest Law in Russia.

WHILE our own Government refuses to take any judicious action looking towards the preservation of our forests, or, to state the case more correctly, while public opinion here is not sufficiently educated on the subject to command its expression in intelligent laws, or to enforce such laws even if they were enacted, the other nations of the world are making efforts to save themselves from the disasters which follow unchecked and unregulated tree cutting. The latest Government to adopt measures for saving its forests is Russia, where, for generations, timber has been recklessly felled and forests plundered. It has long been admitted that stripping the forest cover from the sources of her streams has brought serious changes in the physical and climatic conditions of the empire, one of which is seen in shallower harbors and water-courses. To restrain these evils and restore better conditions so far as may be, a law has been enacted, which is warmly commended by the best organs of public opinion, so that the work of the Commission created by the law is more likely to be carried on with spirit and energy and not in a superficial or perfunctory way. Some of the features of the law are outlined in the following letter from the St. Petersburg correspondent of the London *Times* :

"The new law just promulgated extends to all forests, Government, communal and private, which are to be planned out by a special commission appointed by the Ministry of Imperial Domains, and are to be designated protected woods. The timber thus to be protected may be roughly divided under the following heads: (a) Growing in shifting sand and

obstructing its encroachment on seacoasts, navigable rivers, channels and artificial water courses; (b) sheltering towns, settlements, villages, railways, high roads, post roads, cultivated land, and equally such the removal of which might aid the formation of shifting sands; (c) protecting the shores of navigable rivers, channels and watercourses from landslips, overflows and damage from floating ice; and, lastly, timber and underwood growing on hillsides, cliffs and slopes, if such be found to avert landslips, detachment of rocks, the formation of snow avalanches and rapid torrents. The measures for carrying the foregoing into effect are intrusted to a commission, which elaborates plans not only for the preservation of standing timber, but likewise for the planting of saplings and the proper and regular thinning of forests. With regard to private woods, the measures issued by the commission are to be applied with the consent and co-operation of the proprietors, if possible. If, however, the latter are opposed to such measure, the property is purchased by the State at a certain valuation and the necessary plans carried out. The owners have the right, within a certain period, of repurchasing the property for the same price, but with the addition of the cost of introducing the measures and six per cent. per annum on the capital. In other cases the necessary steps can be taken without purchasing the property at the expense of the proprietor. To enforce the observance of the rules laid down by the commission, new penalties have been promulgated against transgressors, particularly as regards plunder of timber, which is carried on throughout the country to an incredible extent."

Planting the Dunes.

FROM Calais to Hamburg is a long stretch, but for nearly the whole distance the coast line consists of loose sand, now forming flat "links," with a sparse but botanically very interesting vegetation, now blown up into picturesque, irregular hillocks, held together, more or less, by creeping grasses and other plants. In some parts of Kent, in Suffolk and Lincolnshire, the same conditions prevail, but on a smaller scale. However pictorial, or however interesting to the naturalist, such land is, agriculturally, mostly a sterile waste, and it is therefore with no surprise that we learn that the King of the Belgians has interested himself in the matter, and has appointed a commission to study the best means of planting the dunes. We are the less surprised at His Majesty's interest in the matter, as some years ago we were eye-witnesses to the process of digging out His Majesty's villa at Ostend from the sand which had accumulated during the winter above the level of the ground floor windows. The plans for planting the sand hills between Ostend and Blankenberghe have been executed by M. Van der Swaelmen, of Brussels. They are so contrived as to insure protection from the prevailing winds, and when carried out will ultimately form picturesque woods with winding paths, good roads, and other conveniences, which will insure not only an increased agricultural value to the land, but, what is nowadays the most paying of all crops, a crop of villas facing the sea. Those who remember the delightful wood which extends from the Hague to Scheveningen will rejoice that there is now so good a chance of the formation of a similar wood between Ostend and Blankenberghe, a distance of 6 to 7 miles. So far as we are able to judge, M. Van der Swaelmen's plans are admirably adapted to the desired end.—*Gardener's Chronicle*.

Correspondence.

Suggestions for Making a Tennis Lawn.

To the Editor of GARDEN AND FOREST :

Sir.—May I ask you for some instructions about laying down a tennis ground? Being a novice, I should like explicit directions as to leveling, seeding and other details.

Petersville, Michigan.

S. L.

[Minute and explicit directions for making a tennis lawn cannot well be given that will apply to every case. The question of expense, to begin with, is often the most important element of the problem; but even if this be a minor consideration, there will, usually, be other limitations to meet which good judgment and experience will be required. The climate is the main difficulty that has to be contended with in this country, and the mistake most commonly made is insufficient and superficial preparation of the soil before seeding or sodding. This error not only

greatly increases the expense of maintenance, but prevents the attainment of the best results even with the best of care-taking. With a soil of proper texture and sufficiently fertile, it is only required to follow the directions which have been given in former numbers of this journal for making a good lawn, taking special care to have it firm and level. It often happens, however, that a tennis court is wanted where the soil conditions are unfavorable, and then the proper preparation of the soil may be a difficult and expensive task. This preparation of the soil involves two distinct qualities—its mechanical condition and its chemical composition. The soil should be porous enough to absorb sufficient rain water, and to afford ready passage for roots, and yet compact enough to prevent the water absorbed from quickly draining away and evaporating too rapidly; and it should, also, be so firm as not to be stirred up by the grinding action of feet upon it, which would otherwise break the roots and crowns of the grass. In short, the soil should be porous, and yet have a "binding" quality. Sand is porous, but will not bind. Clay will bind, but is not sufficiently porous. A proper mixture of the two will produce the mechanical quality desired.

It is safe to assume that most soils need enriching. For this purpose there is nothing better than rotted barn-yard manure. But it is often more economical to add a mixture of properly prepared peat, muck or leaf mould and commercial lawn fertilizer, than to use barn-yard manure exclusively. The question as to how much manure should be added to a soil is so much one of expense and judgment, that no definite rule can well be given. An ordinary farm field, in fair condition, may have manure, at the rate of twenty cart loads to the acre, plowed in when it is laid down to grass, and a top-dressing of a like amount every three years or so. Ornamental grounds of large extent, in which a better result is desired, and yet in which a careful economy must be observed, may have at least twice that amount plowed in at the start, and an annual top-dressing of half as much to the acre may be applied. A tennis lawn or any other ground upon which turf is to be maintained, that is subject to much wear, may, however, well have more.

The soil of a tennis lawn should be deep, that the roots of the grass may easily descend to permanent ground moisture, just how deep, up to three or four feet, being a question of expense. The topsoil, or mould, and subsoil of good quality, taken together, should extend to that depth if practicable, in order to retain sufficient moisture to last over droughts. It is more economical in the long run so to prepare the soil in the beginning as to store up natural moisture, than it is to supply it artificially upon the surface when needed.

In some instances, however, there will be, at times, too much natural moisture in the soil, and under-drainage is the remedy for such cases. In the case of stiff, clayey soil, another and very important advantage in under-drainage is to make it more porous and pervious to roots. Drainage is best effected by laying land tiles at least two inches in diameter, at a depth of three or four feet and thirty or forty feet apart, care being taken to give them a sufficient pitch and a proper outlet.

For deep preparation of the soil, trenching should be resorted to. This process consists in throwing back the topsoil on a strip from three to ten feet wide, so as to expose the subsoil, which is then dug up and turned over, or thrown back if it is desired to work more deeply. The lumps are pulverized, clay or muck mixed in, if the original soil is too sandy, or sand and peat, if too clayey, and stones, stumps and roots of large size thrown aside, and all necessary grading and leveling done. Then the topsoil of the next strip is thrown upon the strip of subsoil thus prepared, great care being taken to sift out all the roots of weeds and coarse grasses. And so on.

It not infrequently happens in New England and other parts of the country that have been subjected to glacial action and deposit, that both the topsoil and subsoil con-

sist of dry, coarse sand and gravel, upon which it is almost impossible to maintain good turf, after the ordinary preparation, without an extraordinary amount of manure and almost constant watering during dry weather. In such a case, it is an economy to throw back the soil strip by strip, as for trenching, and to place at a depth of three or four feet below the surface a layer of clay about six inches thick, which may be put in dry, if broken to a fine powder, or, which is usually easier, it may be wet and "puddled"—that is, worked into a comparatively homogeneous mass of mud. In either case it forms an impervious bottom to the lawn, thus preventing the rain which falls or the water which is applied from settling down too deep for the roots of the grass to reach it. The sides should, of course, be left sufficiently porous to allow excessive moisture to drain off.

Another case would be where the soil was almost pure clay, and where no muck or sand or finely divided mineral matter could be obtained without excessive cost. In such a case, the ground having been thoroughly under-drained, the usual way is to mix in almost any sort of vegetable fibre, such as leaves, half decayed twigs, leaf mould from the woods, sods, weeds, the tops and refuse of vegetables, and the like.

After the subsoil has been thoroughly prepared, the topsoil is manured and deeply harrowed several times. The ground should then be leveled, rolled and allowed to settle. If the previous work has been well done, the settlement will be uniform; if it is done late in autumn the ground will become none too firm during the winter, and it should not be deeply plowed, but harrowed and leveled as early in spring as it can be worked. If good sod can be procured, the court will be ready for use as soon as the grass is green. The sods, of equal thickness, should be rolled down very firmly, to bring the grass-roots in close contact with the soil. It is a good plan to sow the seed of Kentucky Blue Grass and the finer varieties of Redtop upon the sod as it is laid, and to repeat this sowing every spring. A dressing of some "complete" fertilizer—that is, one that contains nitrogen, potash and phosphoric acid—can also be applied every spring; or fine manure can be spread over the lawn in autumn, to be raked off in spring. In case no sod can be procured, the seeds of the grasses above named can be sown after the ground is leveled and rolled, then lightly raked in and rolled again. If the seeding is done in early spring, the court can be used the same summer; but no seeded lawn is at its best the first season after sowing. Seed can be sown in early September, if the preparation of the soil has been made several weeks before, so as to allow time for settling.

No pains or expense should be spared to obtain the purest and freshest seed, which can best be done by applying to reputable dealers, who have sufficient call for it to warrant them in keeping it. Much disappointment has come from using inferior seed.—ED.]

To the Editor of GARDEN AND FOREST :

Sir.—I was pleased with your description of the *Shepherdia argentea*, and its bright, eatable berries. We grew it abundantly forty years ago, but found that it had a bad habit of letting its branches get ahead of its roots, causing the trees to fall over when ten or twelve feet high.

A notable object here now is *Citrus trifoliata* in fruit. It bids fair to make one of the best hedge plants. Let me add that *Berberis Thunbergii* makes a good hedge; but, in place of all hedges, give me a fence covered with *Lonicera Halleana*. It is a compact mass and as fresh now as in June. The inevitable gap spoils the hedge, but does not hurt a belt of thick shrubbery, which gives flowers at various seasons. The value of autumn flowers is worthy of consideration. A specimen of *Tamarix Chinensis*, as high as the house, is now waving here its graceful racemes of delicate colored flowers to the slightest breeze. It has been blooming since July and will continue blooming until frost. The large orange flowers of *Tecoma grandiflora* are now at their best and very showy. When grown as a pillar it is most striking, and, in time, will make a tree to support itself.

The new variety of *Magnolia parviflora* is now blooming for the second time this season. For it the word exquisite is no exaggeration. Fancy the pure whiteness and the outer petals of *Eucharis amazonica*, with a closely clustered centre of stamens of bright carmine. Add to this a strong perfume of *Magnolia glauca*, tempered with banana, and the result will justify the epithet. *Spiraea bullata* is now blooming here for the second time this season. The foreign papers are just pronouncing upon its *petite* beauty, and yet it has been in the market here for thirteen years, having been introduced by Thomas Hogg.

S. B. Parsons.

Flushing, N. Y., Sept. 1st.

Recent Publications.

A Manual of Orchidaceous Plants.—Part III. *Dendrobium*, *Bulbophyllum* and *Cirrhopetalum*. James Veitch & Sons, London, 1888.

The third part of this important work is devoted to an account of the different species of the genus *Dendrobium*, occupying 91 of the 102 pages, the remainder treating of the two small allied genera, *Bulbophyllum* and *Cirrhopetalum*. Like its predecessors, this part contains numerous illustrations both of individual flowers of many of the species and of fine specimen plants. Maps of south-eastern Asia, including the islands of the East Indian Archipelago and of Australia, show at a glance the geographical distribution of the principal species of *Dendrobium*, an essentially old world genus, of which *Epidendrum* may be taken as the new world representative. The genus, following Bentham in the *Genera Plantarum*, is divided into seven sections, only the fifth and seventh of which contain plants of horticultural value, most of the showy flowered species seen in gardens belonging to the seventh (*Eudendrobiums*). A hundred species, arranged alphabetically, with many varieties, are described, as well as fourteen artificial hybrid *Dendrobiums*; for many of these last Orchid-lovers are indebted to the Veitches' indefatigable enterprise and patient experiments, as we have had occasion to remark of another genus in an earlier notice of this publication.

The present part closes with cultural instruction, based upon long and unrivaled experience, and contains much interesting matter relating to the discovery and introduction into cultivation of many of the species described. Its value, however, as a working manual for the botanist or the horticulturist, would be greatly increased were the species numbered, if each part were not paged separately, and if reference numbers had been added to the illustrations. As now printed it will be practically impossible, almost, to quote this work in subsequent publications.

Quince Culture.—An illustrated hand-book for the propagation and cultivation of the Quince, with descriptions of its varieties, insect-enemies, diseases and their remedies by W. W. Meech. New York: Orange Judd & Co. 1888.

This little manual, as the author explains in his preface, is intended "to furnish all needed information for the profitable cultivation of Quinces in all places where they will grow." That the author has accomplished this task satisfactorily all will agree with us in thinking who read the plain and practical information upon the subjects which he undertakes to discuss. And the public will heartily endorse Mr. Meech's wish "that this fruit, for which there is no substitute, be no longer only a luxury within the means of the rich, but become so common and abundant that it may be enjoyed by all." It is certainly a remarkable fact that so little attention, comparatively, has been given to the cultivation of this useful fruit in the United States, and that when it has been grown, so little care has been paid to the proper management of the trees, that will repay generous treatment as to soil and careful pruning. And yet, Quince culture is so simple a matter that its essentials were all comprised in a brief article in this journal on the 18th of July last. That there are not now, however, more than a dozen varieties of the Quince worth cultivating (of these three or four of the best are of African origin) is not due to the fact that attention has not been devoted to the improvement of this fruit, but rather to its fixed character, which Mr. Meech seems to have overlooked. The Quince, of all the fruits cultivated by man during the past twenty or thirty centuries, is the least modified from its wild state; indeed, the flavor of the wild Quince of Persia varies but little from the best varieties of western gardens. Whether it is ever to lose its harsh flavor and become a dessert fruit is a question which future generations of Pomologists must decide. The improvement of the Quince offers a useful field for horticultural effort.

Periodical Literature.

THE city of Ghent has long been famous as one of the great horticultural centres of the world, and its people are now chiefly known for their love of flowers and their successful and profitable cultivation of them. The following historical facts relating to the early horticultural development of this Belgian city, which owes much of its present prosperity to horticulture, collected by the *Revue de l'Horticulture Belge*, and published at the time of the great quinquennial exhibition, lately held in that city, has, therefore, more than a local interest:

1366. On March 1st, 1366, the Burgomasters passed an order that the flower merchants' stands should be placed in the seed market. (The gardeners of Ghent were not an independent guild, but are supposed to have been connected with the fruiterers' corporation. At Bruges there was a guild of market gardeners.)
1464. Hector de Costere, a Captain from Ghent, on his return from a crusade against the Turks, brought the first Shallots from Escalon, and also the *Convallentulus tricolor*.
1518. Isabella, wife of Christian II., King of Denmark, and sister of Charles V., sent gardeners from Ghent to teach the Danes how to sow seeds and cultivate plants and flowers.
1537. After the conquest of Tunis, Charles V. had a collection of Cappadocian Tulips, and one of Roses, among which was the purple Rose of Tunis, planted in the garden of the *Cour du Prince* in Ghent.
1569. A young monk, P. de Rijcke, brought a collection of new and rare plants from South America.
1596. *Fritillaria imperialis* (The Crown Imperial) and *Lilium candidum* were introduced and cultivated for the first time in Ghent.
1598. William de Blasere, Burgomaster of the city of Ghent, and owner of the best known collection of Orange trees in the sixteenth century, introduced the cultivation of Cucumbers. He built the first hot-houses which are mentioned as having been glazed and heated in the country.
1600. When in 1600 the Archdukes made their grand entry into Ghent, the Abbé d'Ername presented to them, among other gifts, two magnificent *Chamærops humilis*. These trees were planted later in the botanical garden, where one was still alive at the beginning of the present century. The trunk of this tree enabled Morren to illustrate the peculiar structure of Palm-stems, and is still in the botanical laboratory of the University at Liège.
1675. The monk Reyntkens, from the Abbey of St. Peter at Ghent, a great lover of flowers, went to Lille to buy plants. They asked him over sixty-five francs, an enormous sum at that time, for a root of *Cyclamen Persicum*. In one of his works Reyntkens credits the moon with being the cause of the rise of sap in plants.
1742. The *Gazette de Gand* announced the first public sale of plants. Anemones, Ranunculus, Hyacinthis and Tulips were sold.
1749. A French nurseryman from Orleans came to Ghent with a great variety of fruit trees to sell.
1763. *Rhododendron ponticum*, imported from Gibraltar, was planted at Ghent for the first time.
1772. A gardener named Tontje Verstuyft exposed his flowers for sale on a Sunday in June in the *Place d'Armes*. He returned the next Sunday, and was followed by others. From this period dates the flower market, held in the *Place d'Armes* every Sunday during the summer season.
1773. Up to this time the auction sales of plants and flowers, which took place regularly, rarely attracted others than local horticulturists and amateurs, but when in 1774 a gardener, Judocus Huytens, went to England and returned with new plants, others, inspired by his example, did the same.
1797. On the presentation of a report by Charles van Hulthem and Dr. Bernard Coppens the government and municipality established a botanical garden on the spot occupied by the kitchen garden of the monks of St. Benedict in the Abbey of Bandeloo.

In *Chambers' Journal* for August, a chapter on "Eucalyptus Honey" says: "The existence of this particular honey was made known in 1884 by a French traveler, M. Guilmet, who, while exploring the island of Tasmania, noticed at the summit

of one of the Eucalypts a peculiar formation which appeared to be a gigantic gall." Discovering it to be a hive, he proceeded to cut down the tree—a specimen which measured seven metres in circumference—and upon tasting the honey discovered, to his surprise, that it "possessed the characteristic odor and flavor of the Eucalyptus essences." Samples sent to France excited the greatest interest. It was found upon analysis to contain about sixty-two per cent. of the purest sugar, and more than seventeen per cent. of the essential constituents of the Eucalyptus—eucalyptol, eucalyptene, cymol and terpene—all of which play an important part in the therapeutics of to-day. Attempts to produce a similar honey by chemical processes have proved vain, as the ingredients gradually separate and volatilize off. The honey itself, therefore, is believed to be destined to become an important medicinal article, for, given in small quantities, it has already proved very efficacious as a mild stimulant and a remedy for diseases of the throat and respiratory organs. Its antiseptic qualities make it valuable also in such diseases as typhoid, and it promises to replace, to a large degree, cod-liver oil. Unfortunately, the bees which produce the Eucalyptus honey are natives of Australasia only, and all attempts to acclimatize them in Algeria and France have been unavailing. In one Algerian district, where the tree has been naturalized, all the flowering crops were cut off, a year or two ago, to ascertain whether the bees of that country could not be forced to make honey from Eucalyptus blossoms; but the only result was the starvation of the bees, and for the present, at least, the sole source whence the honey can be obtained is Australasia. Here, however, it is said that its production will be undertaken as a regular industry.

Notes.

The new Strawberry, "Early Princess," is highly commended by fruit-growers in Minnesota.

Monsieur H. C. Baillon, the distinguished French botanist, has recently been promoted to the grade of officer in the Order of the Legion of Honor.

Mr. Charles Nichols, Superintendent of the Fairmount Cemetery, Newark, who is President of the Association of American Cemetery Superintendents, states in a recent letter that the membership of the Association has been nearly doubled this year.

The extent to which horticulture is pursued for pleasure merely in Belgium, is shown by the membership list of the Ghent Horticultural Society "Harmonie." In the City of Ghent alone it counts 2,000 members, and of these only 30 are professional gardeners.

The largest Sequoia yet found has lately been discovered, says the *Amador*, California, *Sentinel*, near the headwaters of the Kameah River, on a small basin surrounded on every side by a wall of rugged rocks. The hunter who found it in this almost inaccessible little valley reports that the tree's circumference at a point as high as a man could reach was 160 feet.

Professor Buckhout, of the State College, Pennsylvania, has planted two small plots of ground with forest trees for trial purposes, in connection with the Experiment Station of which Dr. Armsby is Director. One of the plots is on Tussey Mountain, rough and stony, and fairly representing the land which must be dealt with in re-foresting the mountain districts. The other is on the college grounds.

Colonel Pearson writes that the Bordeaux Mixture has proved an efficient preventive of the black rot of the Grape, as well as of Grape mildew. The formula for the mixture, as used this year, is, copper sulphate, six pounds; lime, four pounds, with water to make twenty-two gallons. The lime and sulphate are dissolved separately in hot water, and mixed afterward. With the Eureka Sprayer, made at Vineland, one man can spray five acres a day. If experience corroborates these results elsewhere, the Grape crop of the country can be saved from these two diseases at a trifling expense.

Mr. A. S. Fuller states, in *Orchard and Garden*, that although white varieties have long been known among the native Blackberries, Black Caps, and, in rare instances, among the low bush Huckleberries and Juneberries, there is no record of an albino of our wild red Raspberry (*Rubus strigosus*). Two or three years ago, however, a white Raspberry was detected in McKean County, Pennsylvania, and Mr. Fuller announces that it has fruited with him this summer, the berries being about the same size as the common wild Raspberry; but of a mild flavor, and, in color, almost white, with a slight yellowish tinge when fully ripe.

Dr. Richard Wettstein, according to the *Gardeners' Chronicle*, has published in the *Proceedings* of the Imperial Academy of Science of Vienna the results of his observations on the leaf structure of various reputed hybrids, such as *Pinus Rhaetica* ×, a hybrid between *P. montana* and *P. silvestris*; *P. Neilreichiana* ×, between *P. nigricans* and *P. silvestris*; and also various Junipers. The anatomical characters of the foliage of the hybrids in every case are intermediate between those of the reputed parents, and hence lend confirmation to the opinion that the forms examined are really of hybrid origin.

The production of the true Attar-of-Rose was long confined to the Orient, the Levant and the more southerly Balkan provinces. But during recent years the Roses best adapted for the purpose have been largely planted in the more south-westerly parts of Europe, and oil of a good quality has been there produced. One firm in South Germany, for example, imported, not long ago, 15,000 plants from Bulgaria; but the opportunity for such purchases will not again occur. The Bulgarian government, alarmed at the prospect of a competition which would seriously impair one of the most considerable sources of the country's revenue, has made more stringent a long-existing law against the exportation of Roses, fixing as a penalty the confiscation of the seller's real estate.

Mr. C. G. Pringle has completed the collection of wood specimens of the peculiar trees of the lower Rio Grande valley for the Jesup collection in the New York Museum of Natural History, and has now returned to Chihuahua for the purpose of continuing his investigation of the flora of the Sierra Madre. He has succeeded in securing for the museum fine specimens of *Helietta parvifolia*, *Koerberlinea*, *Condalia obovata*, *Acacia flexicaulis*, the Ebony of the Mexican Boundary, *A. Greggii*, *A. Farnesiana*, *Pithecolobium brevifolium*, *Fraxinus cuspidata*, *Leucana pulverulenta*, *Cordia Boessieri*, *Parkinsonia Texana*, *P. aculeata*, of the undescribed Palmetto which abounds on the banks of the Rio Grande below Brownsville, and of a very fine new Poplar, which is probably quite generally distributed from Saltillo, in Mexico, to southern New Mexico and Arizona. Mr. Pringle was able to secure for the Kew Museum a large trunk of the gigantic *Yucca filifera*.

"A very beautiful dinner-table decoration," says *The Garden*, "was lately arranged entirely with three varieties of single Roses. In some of the slender upright glasses were flowers in various stages of *Rosa macrantha*, and in others of Hebe's Lip, while below were bunches of the exquisite and delightfully fragrant *R. Brunonis*. The flowers, having been cut in the proper stage, lasted well for two days." Arrangements such as this, of a single kind of flower or of two or three closely related kinds, are certainly in much better taste as table decorations than the masses of mixed blossoms we often see, especially when the summer flower-garden offers its endless varieties for our use; and delicately shaped and colored flowers like single Roses, with their correspondingly dainty foliage, are better in place than the coarser or showier flowers which are usually considered "more effective." Neither in the linen, the glass nor the china with which we furnish our tables is showiness considered the most desirable quality; nor should it be in the flowers we employ.

When the English took possession of the island of Cyprus it was annually ravaged by grasshoppers to such a degree that its crops were hardly worth consideration. In five years, and at a cost of only some \$300,000, the insects were almost destroyed, and it now costs but \$8,000 a year to keep the land free from their ravages. The method used to such good effect is now being tried, with results which promise to be equally satisfactory, in Algiers and Spain. When a column of grasshoppers is known to be approaching, a screen formed of cotton cloth, about sixty yards in length and one yard in width, is stretched in front of it, sometimes in a straight and sometimes in a V-shaped line. Along the upper edge of the cloth a strip of oiled or varnished stuff is sewn, over which the insects cannot crawl; and in front of it great pits are dug, the borders of which are encircled by strips of zinc slanting downward. These pits are soon filled with the grasshoppers, which are trampled down by bare-footed natives, and buried under earth with which disinfectants are often mixed. According to *Le Génie Civil*, it is estimated that this year four hundred millions of grasshoppers were thus destroyed in Algiers by the middle of June. It is needful that the screens should be spread in the early morning, when the insects, benumbed by the night cold, are unable to fly over it, and that men should be employed to keep the column as compact as possible.

The Forests of California.

WE begin this week the publication of a series of articles upon forestry, in its relation, principally, to the natural conditions of our Pacific coast. They are from the pen of Mr. Abbot Kinney, the President of the Forestry Commission of the State of California, whose opportunities for studying the actual condition of the California forests and the attitude of the people of that State towards them have been exceptional.

Perhaps nowhere in the world—certainly nowhere on this continent—is the preservation of the forests so important to the welfare of the entire population as it is in California. The physical conditions of the State are peculiar. It is made up of two mountain ranges running parallel with the coast, and inclosing a long, narrow valley, with many smaller, lateral valleys. The rainfall of the year is irregularly distributed, and is entirely wanting during the summer months, so that artificial irrigation is essential for many crops of the field, the orchard and the garden. The water for artificial irrigation must be brought from the mountains, where the snows of the previous winter, melting slowly under the protecting shadows of the forest, afford a constant and sufficient supply. If the forests which cover the mountains are destroyed the snow will melt more rapidly than it does at present, and the water will seek the valleys, not gradually, but suddenly and rapidly. The result will be that the water essential for irrigation will be wasted, and that the short rivers of California, with their precipitous beds, will be converted into torrents every spring and summer, and will gradually carry the soil and the rocks from high mountain-slopes down into the valleys, which, sooner or later, will be buried past redemption.

The future prosperity of California—the very existence of the State—is dependent, therefore, upon the forests which clothe her mountain-sides. These forests are still, in large measure, the property of the general government, and it is within the power of Congress to take measures for their protection. The disregard of the people of California for the property of the national government in that state, and for their own future prosperity, is a matter of

notoriety. Year after year vast herds of sheep and cattle and horses have been driven from the valleys at the beginning of the dry season to feed in the mountain forests. Long ago they stripped the forest-floor bare of every particle of vegetation, except the thorny chapparal bushes, and devoured every seedling tree. The sharp hoofs of sheep and goats have cut out the roots of perennial plants and worn deep, narrow paths across the mountain-sides, down which water can pour unchecked to the rivers. But this is not the only danger which the pasturage of the nation's forests in California has inflicted. As grass and bushes disappear from over-feeding, the shepherds set fires in the woods to burn away the trees, and so increase the pasturage area. The smoke of hundreds of fires may now be seen from any of the high Sierra summits, and it is merely a question of time, under existing conditions, when these forests will have disappeared forever. For forests do not reproduce themselves as easily in the dry climate of western America as they do in all the Eastern States; and if these mountains are once stripped of their tree covering, and the soil is allowed to wash away, their restoration will be the affair of centuries.

The commercial value of the California forests, although secondary to their mechanical value as reservoirs of moisture, is still very considerable. The Redwood forests, to be sure, are doomed, and no action of the general government or of the state government can be made operative soon enough to save them from extermination. The quantity of redwood which remains is comparatively small, the forests are too easy of access, and their product too valuable to make preservation possible, even if the people of California could be made to see the necessity for action in this matter. The Redwood belt of California contained, for its size, thirty years ago, by far the most valuable body of soft timber in the world; in less than thirty years more, Redwood trees of large size will be as rare and as great curiosities as the giant Sequoias are today, and California will have lost her most valuable inheritance.

High up on the slopes of the Sierras, however, there are immense quantities, in the aggregate, of sugar pine still remote and inaccessible, which the general government might well attempt to save for future use when the white pine of the east, the cypress of the south, and the redwood of California have all disappeared before the recklessness of American methods. For in the Sugar Pine belt of the Sierras will then be found their only substitute, not in quantity, but in the quality of the material it can furnish.

If the general government of the United States ever makes the attempt to protect the forests which are found upon the national domain, it is in California that the experiment should be begun, because in California the forests are more essential to the welfare and development of the state than in any other part of the country.

The proper use of herbaceous plants, with more or less showy and conspicuous flowers, in the adornment of parks or of lawns—that is, outside of the flower-garden proper, in which such plants are the most useful and attractive feature—is a matter requiring much judgment and skill in the selection and in the use of material. Indeed, there is no form of planting, perhaps, which is more difficult to master, and which is, within certain limits, at least, more disastrous in effect when it is not well done. That this is not an exaggerated statement, an examination of the attempts which have been made in recent years to introduce these plants into the Central Park in this city, or in the Fens in Boston, will show. Clumps of the *Funkia* or *Day Lily*, in itself a beautiful plant, well suited to the flower-border, for which its round and formal mass of foliage well adapts it, placed in front and in connection with loose masses of deciduous shrubs in the Central Park, produce the worst effect, destroying simple sweeps of turf and all idea of naturalness, while the spotting about of single plants of *Pæony* and

other garden plants in front of shrubs, or often in the lawns at a considerable distance from shrubs, detracts from rather than adds to the beauty of the park. Indeed, it would be vastly benefited if all such inharmonious elements were cleared away and greater simplicity and naturalness allowed to prevail. All such plants are clearly out of place outside the flower-garden. In the Fens, as a part of the new Boston Park system is called, where the attempt is made to connect a salt marsh with the roadway surrounding it, by means of slopes planted in imitation of nature, the effect has been curiously marred by the introduction among the shrubs of great numbers of showy flowered perennials—garden Phloxes, Carpathian Harebells, great masses of brilliant Monardas, Yuccas from the sandy fields of the South, and many more incongruous and inharmonious plants, which seem curiously out of place on the margin of a New England salt-marsh.

There are herbaceous plants, however, which, if used with discretion, can be made to add to almost any landscape, however natural its motive or simple its composition. We have already pointed out in these columns how several varieties of bulbous plants can be used naturally on the margins of woods and shrubberies with the most charming effects, but there are many more robustly growing plants, especially among those which flower at this season of the year, which, if used sparingly, in connection with shrubbery, can be made to play an important part in the decoration of parks. Those herbaceous plants which, when fully grown, approach shrubs in outline, are the best for this purpose, and generally can be used with safety in connection with shrubs. The Flora of North America abounds in such plants—perennial Sunflowers, Silphiums, Rudbeckias, Vernonias, Asters and Golden Rods. No country in the world possesses so many handsome plants of this sort as North America, but they are little known yet except by a few botanists, and their really great decorative value is not appreciated. There is nothing in the habit of such plants which jars upon the most refined taste when they are planted among shrubs, while their flowers, which appear long after those of nearly every shrub have disappeared, light up the shrubbery brilliantly. Even these plants, however, should be used cautiously and never in great masses, in connection with shrubs. A shrubbery in the United States in late September on the borders of which are blooming, just in the right places, a Silphium and a Vernonia, a Sunflower, or one of the great Rudbeckias, is an object not easily forgotten.

August in the Pines.

IT is late in August, and waning summer has held some of her choicest floral treasures until now. On the borders of a pond stands the handsome *Sabbatia chloroides*, its loose panicles of deep rose-colored flowers showing to best advantage against the delicate green of the grasses and sedges about it. Two other species of *Sabbatia* are near by—*S. lanceolata*, which has a flat panicle of white flowers, and *S. stellaris*, with rose-purple corollas almost as beautiful as the first mentioned; the flowers, however, are smaller.

And here among the grasses is the rare *Coreopsis rosea*, with yellow florets and rose-colored rays. *C. lanceolata* is also here, with bright yellow flowers, and rays an inch or more in length. Both species are not only beautiful here, but they will help to brighten any garden, for they take kindly to cultivation.

The pretty Mist-flower (*Conoclinium celestinum*) is just coming into bloom. Its corymbs of blue flowers are as fine as any of the garden Ageratums, which it closely resembles. The climbing Hemp-weed (*Mikania scandens*), with flat corymbs of pale pink flowers and halberd-shaped leaves, is twining over bushes, and hanging out from the main plant are many graceful, drooping sprays swaying in the wind.

The bright orange flowers of *Polygala lutea* are more abundant this month than last. These, together with the Mist-flower and sprays of the climbing Hemp-weed, form a charming combination for house decoration.

Our Pine-barren Gentian (*Gentiana angustiflora*) is just beginning to open its lovely, blue, funnel-shaped flowers. The corollas are two inches in length and quite open. It is almost as pretty as the Fringed Gentian—the queen of these flowers—which has a wide range from New England to our Barrens, and probably further south.

The Shell-flower (*Chelone glabra*), which also has a wide range, finds a home in the Pines, and its companion, the Monkey-flower (*Mimulus ringens*), is here, too. The Purple Gerardia is abundant among the grasses, and is one of our beautiful plants that does not make itself at home in gardens.

Tall plants of the large, showy Rose-mallow (*Hibiscus Moscheutos*), with corollas six inches or more across, are standing like sentinels over their more humble neighbors. Some of the flowers are white with a crimson eye; others are pink and rose-color. The plants and flowers are larger and more stately than the Hollyhocks of our gardens.

Many shrubs and trees are beautiful now in their mature leaves and fruit. *Magnolia glauca*, with its shining, glossy leaves, and red, cone-like fruit, is more handsome now than when in flower. The leaves are perfect, neither insect nor fungus have marred their beauty, and nothing can be more charming for house decoration in large vases than small branches of this Magnolia, with the central fruit surrounded by the rich foliage. The leaves of the Sumach (*Rhus copallina*) are also of the deepest shining green. They have not yet taken on their rich, autumnal tints, and are as perfect as the Magnolias—neither moth nor rust hath corrupted them.

The treacherous poison Sumach (*R. venenata*) is holding out its tempting, beautiful foliage. To many persons it is harmless, but to me it is a virulent poison, and I cannot restrain a cry of fear as I come suddenly upon it, whereupon a boy near by, who is catching frogs, calls out: "Tain't pizen; I have eat it lots o' times," and then he pulls off a handful of leaves and vigorously chews them. On expostulating with him he clinches the argument with, "I know 'tain't pizen. Pop says it won't pizen a chicken." And with lofty scorn for my terror, he continues to chew the leaves so harmful to me, while pursuing his amphibious game.

The Pine-barren Sunflower (*Helianthus angustifolius*), with narrow, long, almost grass-like leaves, is in bloom. This is a very marked and distinct species, and I have never noticed that it hybridizes with any of the other Sunflowers. Some of the plants are six to seven feet in height, full of bloom and very attractive. It does fairly well in cultivation.

Passing from the damp Barren to the dry, sandy woods, I find the Yellow Gerardias (*G. flava* and *G. quercifolia*) in flower, with inflated tubes somewhat of the form of our garden Foxgloves. Fine plants of *Rudbeckia fulgida* are also in bloom, which are always attractive, with their bright, orange-yellow rays, and dark, rounded disks. And here, too, is the Golden Aster (*Chrysopsis Marianna*) and the showy Double-bristled Aster (*Diplopappus linariifolius*), with numerous violet rays and many narrow leaves along the entire length of the stems.

The Blazing-star (*Liatris scariosa*), with long spikes of rose-purple flowers, commands our attention by its erect and stately bearing, while in contrast with it, the Rattlesnake-weed (*Hieracium venosum*) holds its rosette of leaves, which are beautifully veined with purple, close to the ground. From the midst of the leaves rises a slender, naked stem, which branches at the top into a loose corymb of pale yellow flowers.

Away back from cultivated ground, by the side of an old, deserted, nearly obliterated wagon-road, is the Pimpernel, or Poor Man's Weather-glass (*Anagallis arvensis*),

claiming a place among our flowers, and the wonder is how it ever came here. But it is closing its pretty, scarlet flowers, telling us that rain is coming and that our ramble must end.

Vineland, N. J.

Foreign Correspondence.

London Letter.

Olearia Haastii.—This New Zealand composite shrub is now among the most attractive ornaments in English gardens, for of late years it has been used largely in gardens, large and small. A few years ago one could only see it in botanical collections, but, since it has proved hardy everywhere, the wholesale nurserymen have taken it in hand, and it has become diffused throughout Great Britain. In a garden in Kent I have this week seen enormous bushes of it completely whitened with its small Daisy-like blossoms. In one case it was quite seven feet high and as many across. When large it is not such a compact bush as when only a yard or so high, but its leggy growth can be corrected by hard pruning in spring. It is a capital evergreen, and one that stands a smoky atmosphere well, and is therefore much used now in town-gardens. I do not know how many degrees of frost it will stand, but during the severe cold in 1879 and 1880, and also last year, it was unscathed with the thermometer at +12°. I imagine it is hardy enough to endure the winters of your Middle States. Small plants are used with fine effect for lawn-beds, mixed with some bright-colored plant that flowers at the same time, such as *Gladiolus Brenchleyensis*, whose brilliant scarlet spikes make a fine contrast with the white blossom. When out of bloom it reminds one of the Balearic Box.

Salvia azurea grandiflora, which goes also by the name of *S. Pitcheri*, is one of our most useful green-house flowers in summer, and is now in perfection. It is an easily grown pot-plant, or it may be planted in the open border, though it is liable to be winter killed sometimes. We have nothing to compare with this *Salvia* when in perfect bloom. Its spikes of bloom, of the richest azure-blue, are often six inches or nine inches in length, and as the flowers open in succession the plant is attractive for weeks. The plants may be kept from year to year, but early spring-struck cuttings make fine flowering plants by summer, and are more vigorous and flower freer than old plants. Some very charming effects may be produced in the green-house by grouping this Blue Sage with some graceful white-flowered plant, such, for instance, as *Francoa ramosa*, which flowers at the same time. As this *Salvia* is not mentioned in Gray's Manual, I presume it is a native of Mexico, hence its tenderness. [*Salvia azurea*, var. *grandiflora*, is a native of the south-western States from Mississippi to Kansas, Colorado and Texas.—ED.]

A good garden Rose is one called The Pet. It does not grow more than a couple of feet high, makes a wide-spreading mass of shoots, clothed with broad, deep-green foliage, and every shoot terminates in a huge cluster of small white flowers, which, in a bud stage and till half opened, are of a delicate rose pink. It is becoming a great favorite in English gardens, as it is found so useful for cutting.

Lilium auratum is exceptionally fine this season when planted in light soils. The long continuance of heavy rains seems to have suited it wherever the superfluous moisture could drain away quickly, but in heavy soils, even where special lily-beds are prepared, it has been a failure. It is very impatient of stagnant moisture at the root; on the other hand, a moist atmosphere seems to favor a strong growth. In Kew Gardens, at the present time, this Lily is magnificent, intermixed with Rhododendrons in a deep, peaty soil. In many cases the stems are six feet high, as thick as a broom-handle, and bear enormous heads of flowers, many of them fasciated. The finest varieties, too, of *L. auratum* have showed well this season. I saw, the other day at Veitch's, the splendid variety named *Platyphyllum*, which has leaves twice as long and broad as the type, and with flowers nine inches across, with a broad band of gold down the middle of each petal. The variety *Cruentum*, or, as it is often called, *Rubro-vittatum*, I have seen very fine lately in several gardens. The broad band of crimson which runs through each petal of white renders it an extremely showy plant. All Lily-growers on this side, by the way, are anxiously awaiting the time when Parkman's Lily (*L. Parkmani*), a magnificent hybrid between *L. auratum* and *L. speciosum*, will be obtainable by purchase. When I was at the Knap Hill Nurseries last (Mr. Anthony Waterer holds the entire stock of this Lily) I was told that it would be distributed soon. The stock looks very strong

and it seems to be a very robust grower. Your readers may not all know that Parkman's Lily was raised by Mr. Francis Parkman, the historian, twenty years ago. It has flowers a foot across, in shape like those of *L. auratum*, and every petal is a brilliant crimson, broadly edged with white and with a gold band down the centre of each. Other Lilies will be envious when this one appears.

A Hardy Banana is an interesting novelty. It is a species of *Musa* from Japan, growing in the open air in Messrs. Veitch's nursery, and is likely to prove perfectly hardy in England, inasmuch as it has withstood the frosts of the past few seasons with but little or no protection. It has as large leaves as the common Banana, but its growth will, I think, be more like that of the Abyssinian Banana (*Musa Ensete*). The value of a hardy, noble-leaved plant cannot be overestimated, for with it our gardens, without much cost or trouble, may be made to assume a sub-tropical aspect.

London, August 18th, 1888.

Wm. Goldring.

New or Little Known Plants.

Deutzia parviflora.

THE fine *Deutzia* of which a picture appears upon page 365 of this issue, although but little known in gardens, yet is by far the most beautiful of the three or four species now cultivated. It is a native of northern China and the Amoor country, and was sent a few years ago from the St. Petersburg garden to the Arnold Arboretum, whence it has found its way into a few of the principal collections of the United States.

Deutzia parviflora is a stout shrub, with upright stems four or five feet high, covered with exfoliating brownish yellow bark, and sharply serrate, dark green, elliptical or lanceolate leaves, which are pale and conspicuously reticulately veined on the lower surface. The corymbs of handsome white flowers appear here generally during the first week of June, and are produced in the greatest profusion, quite covering for several feet the upper portions of the stems. Maximowicz, in his revision of the genus *Deutzia*, describes nine species. They are all Asiatic, three belonging to the temperate Himalaya region, two to northern China (of these the large-flowered *D. grandiflora* should be a real acquisition in gardens) and four to Japan. There is a very complete analytical drawing of *D. parviflora* (t. iii., Figs. 18-32), in Maximowicz's Revision, published in the tenth volume of the *Mémoires de l'Académie des Sciences de St. Pétersburg*, 7^{me} série, x, and it has been figured by Regel in his "*Flora Ussuriensis*" (t. v., figs. 7-14) and in the *Gartenflora* (1862, t. 370).

It is one of the hardiest and most desirable of the Asiatic shrubs of recent introduction. C. S. S.

Cultural Department.

The Species of *Gladiolus*.

THE genus *Gladiolus*, as at present defined, includes about ninety species. The latest authoritative review of the family to which the genus belongs is in the "*Genera Plantarum*" of Bentham and Hooker, and this differs considerably from Mr. Baker's in the sixteenth volume of the "*Journal of the Linnean Society*," under date of 1878; and as we go backward along the line of botanical literature we find very great variety and even confusion of views as regards the genus. Species of *Ixia*, *Anomatheca*, *Watsonia*, *Acidanthera*, *Tritonia*, *Babiana*, etc., have been considered *Gladioli* by various authors, and many now called *Gladioli* have been previously referred to *Homoglossum*, *Watsonia*, *Geissorhiza* and other genera.

The genus is somewhat widely dispersed. Though by far the greater number of species are South African, one, *G. Illyricus*, strays as far to the north and west as the New Forest in England, and others are found on the Mediterranean coasts and islands and as far eastward as Persia and Afghanistan. A few occur on the western coast of tropical Africa and a few on the eastern, while three or four are indigenous to Madagascar.

This wideness of range indicates great dissimilarity of constitution and requirements among the species; accordingly we find some that flourish with vigor under cultivation and others that die away in spite of all our pains; some that will endure, unprotected, the rigor of a New England winter and

others that will tolerate no frost at all. As the hardiness of a plant, however, does not depend upon temperature alone, the native country of a species affords no sure indication of its ability to withstand severe cold.

The species of the north temperate zone are not, as a class, as showy as the tropical kinds; yet, in their way, they are very beautiful, and, as far as I have tried them, perfectly hardy. According to Baker's enumeration there are fourteen of these and several well-marked varieties. Few of these are in cultivation, though some of them are very desirable, especially the purplish blue *G. Kotschyanus* of Persia.

I find that *G. Byzantinus*, *G. communis* in its three varieties, *G. imbricatus*, *G. Illyricus*, *G. segetum* and *G. triphyllus* withstand the cold of our winters very well, though the last named, a Cypriote species, is a little tender unless in well drained soil and even then it is better for a covering of leaves. It will be found, indeed, that all of these kinds will do better with some protection; and, in fact, without it will increase very slowly, if at all.

The African species are the most satisfactory for horticultural purposes, being, in the main, more beautiful than the others and generally very easy of cultivation. A few of them attain the height of stalk and something approaching the size of flower of the gorgeous garden hybrids so generally cultivated under the name of *G. Gandavensis*.

The following species are best treated as the hybrids just mentioned; that is, planted in the open ground in May and taken up again in October. They may be kept in boxes in a cellar where the winter temperature is about 40° Fahr.

G. purpureo-auratus.—This is a native of Natal. It has stiff, narrow and somewhat glaucous foliage, and a slender but rigid flower-stalk about three feet high. The flowers are from six to ten, of a peculiar shape, the upper segment being curved over like a hood. They are not large, an inch and a half being the average breadth, and are yellow, with blotches of a color between crimson and purple. The ground color is by no means as strong and pure a yellow as in the figure in the *Botanical Magazine* (t. 5944), but rather somewhat greenish. This species is likely to be better known in its offspring than in its own person, for it is one parent of the "Lemoine hybrids," so-called, which are remarkable for their vivid blotches and their peculiar shape; both of which characteristics are derived from the species under consideration.

G. purpureo-auratus seldom seeds from the influence of its own pollen; such, at least, is my experience, for though I grow a great many every year in one mass, from the seed of which I have raised many hundred plants, I have never had but two seedlings which did not show the influence of the *Gandavensis* varieties growing near them. This species forms a great many bulblets which lie a little way from the old corm, to which they are joined by short connectives. They have a thinner coating than those of the *Gandavensis* sorts and start into growth more readily. This is the hardest of the African species. I have known it to come up for several years among the grass in a mowing-field.

G. floribundus.—This is a very pretty low-growing kind, bearing from ten to twenty blush-white flowers on a stem about eighteen inches high. These are never fully open as we are accustomed to see *Gladioli*, but retain a half-closed appearance. They are usually somewhat crisped along the edges.

G. cardinalis.—A very brilliant scarlet and white species of low stature and great beauty. The bulbs of this, as well as of the hybrids of which it is a parent, viz., *G. Colvillei*, *ramosus*, *pubibundus*, *candidus* and *incarnatus*, will not endure being kept long out of the ground; at the same time, if left in the soil late in the summer they will make an autumnal growth to which the winter will be fatal; they ought, therefore, to be lifted a month after flowering and replanted in October either in a frame or in a raised bed of earth with a thick covering of leaves.

G. cruentus.—This is a magnificent species from Natal. Its manner of growth is very peculiar, for, while many kinds may be put into the ground on their sides or tops, as well as on their bases, the shoots arising perpendicularly from the soil, the shoots of this species appear to grow straight away from the centre of the corm and hence enter the air at all angles. The foliage is drooping, unlike any other kind, while the bulb is dissimilar to all others, being bright yellow, almost globular and scantily covered with a very thin papery husk. The flowers, though few, are very showy, deep crimson with an irregular band of white across the three lower segments. They are four and sometimes five inches across.

G. cruentus has one bad fault; it is a very late bloomer. This can be offset by early planting by those who can plant when they please.

G. psittacinus.—A peculiar and not very showy species. It has short, rigid foliage and flower-stalks about two feet high. The flowers are yellow, thickly dotted and lined mahogany red; throat yellow. The flowers are narrow and appear to only half open. Seedlings from this vary somewhat, though unmixed with any other kind. Among twenty raised from pure seed there are six which differ considerably from their parent, though plainly *G. psittacinus*, and nothing else. One or two of these are very handsome. This species and the next increase more rapidly, both by bulblets and by growth from the buds of the old corm, than any others I have seen; unhappily, they are the least desirable.

G. dracocephalus.—A very tall species (four and one-half or five feet), with a spike of narrow, inconspicuous flowers, green, spotted and grained with dull red. This, on my grounds, never has perfect anthers, and I have never been able to get a grain of pollen.

G. Saundersii.—This very beautiful species is offered for sale by nearly every dealer, and is, presumably, better known than most others. Its foliage is short and quite glaucous; the flower-stem not high and its flowers large and very showy, being scarlet mottled on the lower half with white; their form, also, is very elegant. Taken for all in all, this is one of the very best species.

The following being small in bulb and plant and flower, will give most satisfaction as pot plants. They should be grown in four or five inch pots in light, rich soil, and should, for the most part, be potted in late autumn.

G. tristis.—Like very many of the African species, this has narrow, almost rush-like foliage. I have been most pleased with this plant when I have potted the bulbs in autumn and kept them through the winter in the green-house, though like many, perhaps all, of the tender species, it may be successfully carried through out-of-doors if deeply planted in a dry soil and well covered with leaves. With me it blossoms in April, the flowers being four or five, comparatively large, of a light creamy tint, sprinkled with small dark spots, and strongly fragrant from dusk to dawn. How excellently adapted to insect fertilization! How plain that it is fecundated by some nocturnal moth allured by the large light flowers, whose powerful fragrance exists only during the hours of darkness! Unhappily for the theorists, who know so well why fragrance was given to flowers, however, *Gladiolus tristis* is perfectly self-fertilizing. It does not depend upon nocturnal or diurnal insects, but every blossom, even when protected from insect visits by gauze, will form a capsule of perfect seed. From such I have raised scores of seedlings. It is to me evident that perfume is not always (even if ever) provided to insure fertilization by means of insects.

G. recurvus, called also *G. ringens*, is best treated like *G. tristis*, as it is a weakly-growing kind. Its flowers, though few, are very pretty, being of a shade of lilac approaching blue, with a whitish throat.

G. gracilis.—A slender plant, with two or three lilac and black flowers. Though apparently hardier than many sorts, it is too delicate for the open ground.

G. cuspidatus.—Another rush-leaved kind, with flowers of a singular shape. Their segments are very long, narrow and twisted. Color, creamy white, blotched with purple and yellow.

G. villosus.—I received this three years ago and have been very unsuccessful with it, having seen, so far, but one flower. This was borne on a stalk ten inches high and was of a pinkish color. The entire plant is covered with short, fine hairs. Hence its name. This is not the *G. hirsutus* of Jacquin, but of Ker.

G. Milleri is a pretty species of small stature, with light yellow flowers.

G. alatus.—I have tried this species many times, but all in vain; it will not flower nor can I keep it. The bulb starts readily enough and so does the seed when obtainable. I have now over a hundred seedlings three years old and no larger than a grain of rice. If we may trust the published figures, this is one of the most beautiful species. Its colors are scarlet, yellow and orange.

G. sulphureus, considered by some to be a variety of *Babiana stricta*, is a small species, but robust enough to maintain itself in the open ground. Flowers few, yellow, but of a deeper shade than the name implies.

G. Watsonius.—This is called by Baker a species of *Homoglossum*, a genus not admitted by Bentham and Hooker. I have had it only during the present season. In April I received fifty bulbs of it from the Cape of Good Hope, some of which I found had started into growth. I potted them and they bloomed in June. The foliage is plaited in four strong

Fig. 57.—*Deutzia parviflora*.—See page 363.

folys. The flowers are of an intense vermilion color. A very desirable kind.

G. carneus.—At least four different plants have borne the name. I seem to have the one figured in Redoute's "*Liliaceæ*." It is pretty, though not showy. The ground color is pink with darker blotches on the lower segments. I have known

this to endure a severe winter out-of-doors and blossom well the following June. I prefer to cultivate it in a pot.

I have many other species which I have not yet seen in flower, and of which I do not now wish to speak. At some future time I hope to describe them from my own knowledge.

W. E. Endicott.

The Vegetable Garden.

DURING the week of the Florists' Convention leading seedsmen of the city had special exhibitions of flowers, and some of them of vegetables as well, in their stores. In one of these the display of vegetables was excellent in itself, and, as everything was carefully and legibly named, the interest in, and usefulness of, the exhibit, was thereby much enhanced.

The mammoth Sugar Corn showed its superiority. It is a capital Corn, with large, well-filled ears and white fruit, but rather too big for table use. Most people prefer smaller Corn, like Squantum. Cucumbers showed nothing better than White Spine. Under the name of White German were exhibited large, white-skinned Cucumbers; but either for market or private use the green-skinned Cucumbers only can become popular. A large and beautiful specimen of the new Watermelon, "Green and Gold," cut open, was exhibited. The flesh is solid throughout, and of a butter-yellow color, and the rind quite thin. But no matter how delicious this Melon may be, the popular Watermelon must have red flesh and black seed. Kolb's Gem is such a Melon. It was exhibited, cut open, alongside of Green and Gold. The Hackensack was shown as the standard green-fleshed Muskmelon in the neighborhood of New York, and so it is. It is a large-fruited variety, rather coarse, but of good quality. The vines are vigorous growers, and bear a heavy crop of large, even-sized fruit, and it shows

largest Pepper, and no doubt will become the most popular variety. Celestial Pepper, a variety introduced from China three years ago, and first distributed this year, was also shown. The fruit is under medium size, green at first, changing to yellow tinged with purple, and ripens off scarlet. It is as pungent as most other Peppers. It is extremely prolific, and the fruit stands upright on the plants instead of nodding, as is the case with most large Peppers. It will hardly gain a foothold in our gardens except as an ornamental plant.

White Velvet was the conspicuous Okra. This is a new variety of dwarf habit, and with long, round, white pods. But, except in fixing the dwarfness of Okra, I question if we have lately made much progress in it. I sowed all the popular varieties May 24th last in rows alongside of each other. On July 25th we were picking from Dwarf Density, but not from any of the others. We did not begin picking from White Velvet till August.

A green plant of the new Dwarf Sieva Bean was shown full of seed-pods. In its line it is a decided acquisition. With it we can enjoy these delicious Beans without the bother of poles. The Dwarf Lima Bean was also exhibited full of green pods. A really dwarf Lima will be one of the most desirable vegetables ever introduced. We cannot reasonably expect to gather as heavy a crop of Limas from dwarf as from pole plants, nor that the dwarf plants would continue as long in bearing green Beans; but for many amateurs these dwarf

Fig. 58.—Root-stock of *Nymphaea tuberosa*.—See page 368.

less tendency to premature decay than any other variety. Among salmon-fleshed varieties, Emerald Gem has no superior; indeed, it is as good in quality as the much-lauded European varieties grown in warm green-houses there, but which cannot be grown satisfactorily out-of-doors in this country. It is not a large Melon, but its flesh is exceptionally thick, sweet, buttery, and ripens up to the thin rind. Indeed, Emerald Gem as a red-fleshed, and Hackensack as a green-fleshed Melon, are our standard varieties around New York.

Among the many Tomatoes, Acme, Perfection and Trophy were as handsome as any. Mikado was the largest, perhaps, and a yellow-skinned form of it was also shown; but although yellow-skinned Tomatoes, such as Green Gage and Golden Queen, may have their special uses and friends, the popular Tomato must be red-skinned, and of round, even outline. An uncommonly large, reddish-fruited variety, named President Garfield, of very uneven form and many-ribbed, showed plainly what ought to be avoided among Tomatoes. The Dwarf Champion Tomato, sent out last year as a new variety, has round, even, fair-sized red fruit, and is really a desirable sort. It is of more compact growth than the other Tomatoes, and quite prolific, but it will not stand erect without supports any more than any other variety. Thirty-seven dishes of the Puritan Potato occupied one table, and represented the products of every section of the country.—Maine, California, Texas, Georgia and other states. The Georgia tubers were the finest. This is a new Potato, raised by Mr. Coy from seed saved from Beauty of Hebron in 1882. The tubers are white-skinned and of the form of the well-known Snowflake. The Beauty of Hebron also originated with Mr. Coy. Ruby King was the

Limas will be valuable, because they will do away with the annoyance of getting and keeping and setting up bean-poles.
Glen Cove, N. Y. Wm. Falconer.

Orchids.—*Phalanopsis Mariae*.—This is a somewhat rare species, very strong in growth, producing a drooping, branched spike bearing a number of white flowers, barred and blotched with amethyst, the crimson lip being edged with white. Coming from Borneo, this plant requires abundance of heat and water, and should at no time be allowed to become dry. It seems to do far better with us in a tall cylinder than in a basket. The roots running to the bottom and forming quite a network, both inside and out, we use scarcely any potting material in the cylinders, but water overhead three to four times a day.

Lalia crispa.—Plants of this useful species are now in full beauty. Though an old and comparatively common Orchid, one seldom sees it in good condition. It is often too much coddled and grown too hot. All the best-grown and well-flowered specimens I have met with were grown under cool treatment, and some of the spikes have had ten or twelve flowers, and very large, while the usual number is but five or six. It is a beautiful Orchid, and did it but flower in midwinter would be highly prized by florists. The flowers are five to six inches across, pure white, and much curled or twisted. The lip is a rich crimson, edged with white, and beautifully crisp. It will grow well under the same treatment accorded to *L. anceps*, and, like it, prefers not to have its roots at all confined. The white variety of *Lalia elegans* may be had in flower nearly every month in the year—that is, if the plant be very

large, as the growths never appear all together. The individual spikes are very beautiful, and when cut, need only the addition of a few Ferns to make a handsome bouquet. This variety requires an intermediate temperature, abundance of air, and as much sunlight as can be given without burning the leaves.

tion to its great beauty it is interesting as being the first hybrid *Cattleya* artificially produced. Like all of this section of two-leaved *Cattleyas*, it is very difficult to keep in good condition for a long time, but it is now growing freely in the warmest end of the house. It should be kept somewhat cool and dry during the resting season.

Fig. 59.—*Nymphaea tuberosa*.—See page 368.

Cattleya hybrida picta.—This is a very pretty hybrid between *C. guttata* and *C. intermedia*, in growth partaking of an intermediate character, while the flowers are more in the way of *C. guttata*, being of a pale olive green, beautifully speckled with purple, the petals being margined with pale rosy mauve. The front lobe of the lip is a deep purple, the lateral lobes and the column pure white. This is a very rare plant, if not the only specimen, while the typical hybrida is now lost. In addition

Phalanopsis Esmeralda.—This is a small-flowered but very attractive Orchid, and very useful, because flowering at a season when every flower is appreciated. It produces racemes from one to two feet long, sometimes branched, bearing eighteen to twenty flowers of a beautiful amethyst color, lasting a long time in perfection. There are many varieties, the best being *Regnier*, with larger and brighter-colored flowers. We have been most successful with these plants when grow-

ing them in a mixture of peat, loam and leaf-mould, with a little sphagnum moss, and potted in either pots or pans. They should have strong heat and abundance of water during growth, and should be kept very dry during the winter. They can be very easily propagated. The stem, which is made very quickly, may be cut into lengths of about an inch, potted into small pots, and put into a close frame. Every piece will break and make a nice plant in one season.

Kenwood, N. Y.

F. Goldring.

Ranunculus.—Representatives of this genus are found in all temperate regions of the globe. The majority are natives of the northern hemisphere. *R. Lyalli* comes from New Zealand; *R. cortusaeifolius* from the mountains of Teneriffe; *R. bulbosus*, *R. acris* and *R. aquatilis* are found in every temperate part of the globe, though probably, in many cases, naturalized. All enjoy a moist soil. General neatness of habit and the free production of blooms characterize all the species; and although the flowers, which are nearly always white or yellow in color, are often small, yet the neatness of their arrangement and symmetry of form always make them attractive. The majority are adapted for culture in the rock-garden.

The Persian and Turban forms of *R. Asiaticus* were once largely used for spring bedding. It used to be the pride of the old-time gardeners to "do them well." The art of doing them well now seems to be lost. It is a long time ago since I saw an unbroken, compact bed of them. Success is best attained by spring planting, especially in this country. As soon as the foliage begins to turn yellow they should be taken up and carefully matured in moderately moist sand. We must expect failure as long as we keep cutting them over as soon as past blooming, and otherwise disturbing them in order to plant Geraniums, Coleus and other summer bedding plants. It is further necessary to have the soil previously enriched—say, with a surface dressing of manure in the fall: Manure freshly put on in spring encourages the millepedes, which prey on bulbous plants when at rest, if left in the ground. It would be better if all bulbous plants were taken up after ripening.

A selection of the best kinds for the rock-garden include *R. acris*, fl. pl., otherwise known as *R. speciosus*, pl., a good double yellow; *R. amplexicaulis*, with large, pure white flowers and glaucous foliage; *R. anemonoides*, of dwarf habit, flowers white, pink-tinted, almost stemless, with elegant, glaucous, much-divided foliage. *R. Ficaria* is the common Pilewort. In some parts of England it is a common weed, growing under trees where grass refuses to grow. Under cultivation it is quite a pretty plant, its flowers coming double. *R. fumariaefolius* has elegant Fern-like foliage, and small, double yellow flowers. *R. spicatus* is a very rare tuberous-rooted species from northern Africa, adapted only for culture in the green-house. If only for its being a distinct and peculiar Buttercup, it is worth growing; but it has handsome palmate foliage, and large yellow flowers, appearing and flowering only in the fall and winter, and dying down towards spring.

T. D. Hatfield.

Roses.—Pot-grown Hybrid Perpetuals for early forcing should now be ripening their growth, as only solid, well-ripened wood may be depended on for this purpose. And in this ripening process some care is necessary, as they should not be allowed to become so dry that the wood shrivels, as such a condition works injury rather than benefit to the plants, and usually results in a weak growth and few flowers when forced. Hybrids grown in the open ground during the summer, and lifted in preparation for winter forcing, are frequently better if held back so as to come in as a second crop; the pot-grown plants being used for the first, as the roots of the latter are likely to be in a better condition to stand the extra exertion of early forcing. If regular Hybrid houses are used, in which the Roses are planted out in solid beds or on benches, the growth will be more readily matured by stripping off the sashes during the summer months and leaving them off until cold weather, provided the season is not too damp, as in the latter case the shoots remain too soft and sappy for early work. And in the planting of such houses it is well to group the varieties used, so that the earliest sorts may be planted in one house, or section of a house, and those more obstinate in regard to forcing may be placed by themselves in another section, to be used for a later crop, thereby insuring a succession of bloom. For instance, such Roses as Anna de Diesbach, Magna Charta and possibly Mrs. John Laing may be used for early flowers, to be followed by Paul Neyron, Baroness Rothschild, Mabel Morrison, Captain Christy and Alfred de Rougemont, and a number of others equally good for this purpose, if it is thought desirable to use a more extended list. One variety in particular, the ever-popular

General Jacqueminot, should certainly be added to either or both catalogues, for, when properly managed, this old favorite may be flowered as early as any of its class

"W."

Philadelphia, Pa.

Quinces on Apple Stocks.—A correspondent wishes to know whether he can grow Quinces on Apple stocks by the root-grafting process, and whether the quality of the fruit would probably be affected?

Yes, he can grow the Quince in this way. The so-called Meech Quince has been propagated by tens of thousands in this way. Whatever effect this mingling of blood might exert upon stock or graft can hardly be known, but the effect on the fruit would probably be slight. The Quince is generally and readily grown from cuttings in moist soils. Its tendency is to make a mass of fine fibrous roots. The Apple makes no such mass, and if its roots were the sole dependence of graft and stock the growth would probably be affected. But as both stock and graft are planted below the surface of the ground, the Quince would eventually root, the Apple stock acting as a support or starter till the Quince roots were produced. This is the result in the case of Dwarf Pears on Quince stock. When the Pear stocks root above the Quince, the trees become standard Pear trees, and the Quince stock finally dies or becomes so enfeebled as to be of no further use, because, perhaps, their natural rooting place is near the surface. Whether this would be the final result of the Apple and Quince union I do not know, and I hardly think the practice has been tried long enough to determine. My experience with Pears on Apple stocks is that they make a feeble growth for a few years, and finally die. The incompatibility is fatal.

Time and experience with the uncongenial affinities of Pear and Apple has tended to materially modify the Dwarf Pear craze, so popular twenty-five years ago, so that its most zealous advocates are seldom heard from now, and some have so far revised their opinions as to declare they would not plant them as a gift. In conclusion, I think it safe to say that the practice of root-grafting the Quince on Apple is only admissible in case of rare or scarce varieties.

E. W.

The Peach Yellows.—A case is cited in *Orchard and Garden* where a Peach tree standing in rich ground showed this spring every symptom of the yellows. Early in July a quart of muriate of potash was forked into the soil about it with magical effect. New and healthy foliage began to appear, and within a fortnight after the application the tree appeared in good health. This corroborates the experience of many peach-growers in New Jersey, who have found potash, as recommended by Dr. Goessmann, a sovereign remedy for many trees apparently afflicted with the yellows. Indeed, so often has this cure been repeated, that many peach-growers in that state do not believe that there is any such disease. The only disease they fear is starvation. On the other hand, peach-growers in Michigan are thoroughly convinced that such a disease exists, and that it is incurable. Indeed, laws have been enacted to enforce the destruction of affected trees, and thus prevent the spread of what is considered a most dangerous contagion.

Perhaps, under the circumstances, it would be well to refrain from enforcing the law to exterminate diseased trees until the potash cure had been tried. Admitting the existence of a genuine disease, it is not impossible that a lack of some constituent in the soil may enfeeble Peach trees, and give them the same appearance as that of trees affected by the disease. If an application of kainit or other form of potash will save the trees and renew their vigor when in this condition, it would be well to try the potash remedy before the more heroic one is resorted to.

S.

Plant Notes.

Nymphaea tuberosa.

THE figure of this handsome Water Lily which appears in the present issue is the first which has been published, unless the doubtful *N. reniformis* of De Candolle, figured by Delessert in his "*Icones Selectae*" (ii, 3, t. 5), is really the same plant. *N. tuberosa* was first made known by Paine in his "Catalogue of the Plants of Oneida County, New York," published in 1865. It may be distinguished from the common species of eastern North America (*N. odorata*), with which, doubtlessly, it is often confounded, by the thicker root-stock (see Fig. 58), bearing spontaneously-detaching and often compound tubers, by the much larger and more prominently veined leaves, green on both faces, and which, when fully grown, are

often raised above the surface of the water on the stout petioles; and by the much larger flowers, four to ten inches in diameter when expanded, the petals proportionally broader and blunter than in *N. odorata*. The flowers are scentless, or almost so. The fruit is depressed-globular, with few globular-ovoid seeds, barely enclosed in the aril at maturity.

N. tuberosa is the common Water Lily of Lake Champlain and of the waters which flow into it. It has recently been detected in a very depauperate form near Trenton, New Jersey, by Dr. Abbott, and it occurs at Meadville, in Pennsylvania. These are the only places where it has been noticed near the Atlantic sea-board, but it is said to be common from western New York, west and south, but its distribution is not yet at all well known. It is one of the most beautiful of all the Nymphæas, and by far the most beautiful of those which can be grown in the Northern States without artificial heat, equaling *N. odorata* in the delicacy of its petals, although the flowers lack the delicious fragrance of that species.

N. tuberosa is easily cultivated; indeed, when once established, it increases so rapidly by means of the detaching tubers and by seed, that it is sometimes difficult to keep it within reasonable bounds.

The flowers (on cultivated plants) open about eight o'clock in the morning, and close in pleasant weather between two and three o'clock in the afternoon. They open twice or sometimes three times if the weather is overcast.

C. S. S.

The Forest.

Forestry in California.—I.

THE first business thought of a practical person in looking at a forest is, What are its products worth—that is, what can be made out of it? For the products of the forest enter into the life of every one. The varnish of the artist, the rubber, the gums, the resins of commerce, the barks of the tanner, the corks of the vintner, the handles of our tools, hoes, plows, etc., our dye-stuffs, our wagons, the ties and cars of our railroads, fences and telegraph-poles, furniture, wharves, boats, ships, and in America, even the houses we live in, are largely the product of the forest. Few people appreciate what the annual drain on our forests is; even such small things as matches consume great amounts of lumber every year; charcoal and fuel are a great drain on our forests; even coal is but a fossilized form of wood. Nuts, fruits and medicines, such as cocaine, quinine, etc., cannot be overlooked. When we thus consider the products of the forest, it will not be a surprise to learn that these were estimated in the United States for the year 1880 at \$800,000,000. The last government statistics at my command show some of our principal crops to have been:

Wheat,	\$474,291,850
Cotton,	280,266,242
Gold and Silver,	74,400,000
Coal,	94,500,000
Iron Ore,	20,470,000

It will thus be seen that the economic value of our forest products is nearly double that of wheat, more than ten times that of gold and silver, and forty times that of iron ore. The census, the agricultural reports, the recorded observations of intelligent men, as well as the individual experience of every one who has by travel become acquainted with the country, show that the consumption and destruction of our forests now so far outruns their reproductive capacity, that at the present rate in a few years we shall have no forests at all, and their vast crop, valued at \$800,000,000 a year, must disappear from our census books. We are eating into our capital and providing for no renewal of it. It is not alone the good lumber and firewood taken that we must calculate on, but the waste that accompanies it, and the destruction annually caused by fire. These the best authorities state to be even greater than the drains of commerce.

Forest fires destroy every year millions of this, the people's property, and blacken and mar the landscape. Besides, the lumbermen, in the prosecution of their business, waste fully as much timber as they use. In my visits to Mendocino County, and other centres of lumbering activity in this state, I have seen left to rot or burn large portions of the trees felled,

and again and again I have seen magnificent trees felled and left untouched because they did not fall right, or for some other trifling reason. In this way much lumber is wasted and firewood enough is annually destroyed to supply the whole of California for years.

Besides the waste, this *débris* in the oft-recurring fires makes an intense flame and heat, endangering all neighboring forests and destroying, often entirely, and always much of the woods they traverse; and also the humus in and above the earth. It may be well to say just here to those having lands to clear that it has now been demonstrated thoroughly that burning over land destroys the best part of the soil, and thus permanently injures its producing capacity. The hotter the fire, the deeper it destroys the soil. Experiments in Canada show that a hundred years of repose and forest action will often not re-establish the strength and fertility of the soil passed over by hot fires.

Besides the regular lumbermen, who operate on a large scale, there are numbers of individuals engaged in making shakes, etc., who use only selected trees, chiefly the Sugar Pine, which in this state reaches a great size, is very valuable, but does not readily reproduce itself. To be used advantageously for this purpose, these trees must be in certain conditions, which can only be told after they are felled. Thus thousands of trees, and of the very best, are annually felled and found unsuitable, and left to rot. At the best these men only use about twenty feet of the magnificent trees they cut, the rest being waste. The Sugar Pine is fast disappearing. The tan-bark men also destroy great numbers of trees, taking only the bark. I have seen in this state, in one place, woodmen destroying trees, cutting off only the branches for firewood, and leaving the trunk and bark unused. In other places the lumbermen leave the branches and firewood, and taking only the trunks; again, tan-bark men leave the entire trees, using only the bark. It may not be a crime to allow such unnecessary waste, but it is unmitigated folly to be thus throwing right and left a property that brings us in \$800,000,000 a year.

The forests are also much injured by sheep and goats that are driven into them for a few weeks' pasturage; these destroy the young trees and pack the ground so that it cannot so well receive and hold moisture. Besides this, the shepherds often deliberately set fires to open the country, or, as they say, to improve the pasture, thus destroying, in one season, more lumber, fire-wood, etc., than the value of all the sheep and goats and their products that have or ever will visit the scant mountain pastures.

Every considerable government of Europe now has its forestry department. Every one of them gives a net revenue. The system pursued is nearly the same in all. By it the forests are preserved and increased in area; at the same time the maximum of fire-wood and lumber consistent with this preservation is taken out; no waste is allowed.

The revenues from these departments show that a large, properly managed forest is a source of income. Saxony has a net annual income of \$3.25 from each acre in her total forest area. Alsace-Lorraine about the same. British India, although a new convert and under heavy expenses, had, according to the last returns in my hands, a net income from her forest lands of over one million dollars.

All the European governments, save England, which is exceptionally situated, have forest departments served by men instructed in forest schools, some of which are celebrated, such as those at Hanover, Aschaffenberg, Minden and Nancy, each department giving more or less net revenue. In Austria, Italy and France considerable works in forest planting, from which little or no direct revenue can be expected, are being done.

Such desolate places as the Karst, in Austria, and the Landes, in France, are thus being reclaimed. Trees are also being extensively planted on the water-sheds of rivers and torrents; in the first case the object is to re-establish regularity of flow in the streams, and in the second by preventing the rapid delivery of heavy rains from bare surfaces, to reduce and eventually end the destructive action of rivers which are either beds of bowlders or glittering wastes of sand, or rushing torrents of turbulent water, charged with mountain *débris* and carrying destruction in their course to the valley lands. These works of the foresters are productive to the nation, but show no revenue to their department, a fact that must be taken into consideration in the economic management of forests. But some of these works have become remunerative. The Pine plantations on the south-west coast of France, about Arcachon, to reclaim the desolate Landes, are of these. In that section the sand dunes of the coast were rapidly advancing on the interior in hills over 200 feet high; fields, houses,

villages and even church steeples were entirely buried out of sight. Major F. Bailey, R.E., in a recent trip to the Landes, speaks of his guide tying his horse to the projecting point of one of these covered church steeples.

The planting of these forests near the coast, together with the preliminary work necessary to establish their growth and stop the rolling sands, cost the French government about \$40 per acre. Tracts in these forests are now rented for five years, with the privilege of cutting selected trees and tapping others for resin, at a price equaling about \$70 per acre. It will thus be seen that under even adverse circumstances a scientific forest management, designed for protection to a country rather than for direct profit, may be made remunerative.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—The article, with illustration, in GARDEN AND FOREST, July 11th, assumes, not without reason, that *Rosa laevigata* is a foreign species, introduced and naturalized through a large part of the South Atlantic and Gulf States. Nevertheless, it seems to me that, in the absence of positive proof of its introduction, it is still a question whether Michaux was not correct in considering it a native. The plant was known as the Cherokee Rose at least a century ago, and this fact seems to indicate that it found its way into the white settlements nearer the coast from the Cherokee country in upper Georgia and the Carolinas. More than fifty years it was known in cultivation at Salem, North Carolina, and vicinity, where the evergreen foliage sometimes suffered from the severity of the winters. The tradition there was that it had been introduced from the "Cherokee Country," having been brought by Moravian missionaries of Salem, whose stations were in the region which has since become famous through the battles fought in the late war—Mission Ridge, Lookout Mountain, etc.

Elliott, in his "Botany of South Carolina and Georgia," published in 1821, speaks of it (as stated in the article referred to) as having been cultivated in the gardens of Georgia for upwards of forty years, therefore as early as in the years of the Revolutionary War. If introduced from abroad, it must have been when the settlements of Georgia had scarcely reached the upper country—Savannah having been founded in 1733—and it is difficult to conceive that it should have been designated from the first as the *Cherokee* Rose if it reached the country through the lower settlements, and that it should have become so common and well-established about one hundred years ago that the careful and experienced observer, Michaux, "mistook it for a native plant." Was he not right?

On referring to Grisebach's "Flora of the British West Indian Islands," I find *Rosa laevigata* given (on the authority of an old friend of mine) as "naturalized in Jamaica," and he adds, "introduced from China and Japan." The question arises, Was it not rather introduced in Colonial times from Charleston or Savannah, when intercourse and trade were frequent? Although the plant flourishes luxuriantly in the mountain regions, it exhibits unmistakable evidences of its introduction from abroad. More than fifty years ago it could be met with near houses, and usually covering stone-walls. It was not regarded as a rare plant or of recent introduction, the persons inquired of usually being ignorant of the way it got there. In the year 1848, passing a deserted coffee-plantation in the interior of the island, among the mountains, I came upon what had evidently at one time been a hedge of Cherokee Rose. The plants had spread and flourished until they covered a space twenty feet broad, and formed a mass higher than a man's head on horseback, probably outdoing those in the illustration by Dr. Lanborn. The shining foliage and the hundreds of pure white Roses formed a beautiful sight—all the more striking and surprising because (with the exception of *Rubus Jamaicensis*) it was the only representative of the order Rosaceæ I had met with in a flourishing and apparently naturalized condition. Trees that had grown up spontaneously, and the deserted and decayed buildings, indicated that cultivation had been abandoned for many years—probably not less than twenty—but there was the long, straight line, indicating unmistakably the original hedge. And it was this hedge idea (the use to which the species is generally put in the Southern States) which seemed to me, at the time, a reason for thinking that the plant had been introduced direct from our own country, and not from England, whence it must have come, if not from the United States.

If, in the island of Jamaica, under the most favorable conditions, and after many years, it is unmistakably evident that the plant was introduced, is it likely that in Georgia, where

the plant, if introduced, could not possibly have been an inhabitant longer than I found it in Jamaica, it should have outgrown the evidences of its introduction so as to deceive Michaux into regarding it as a native?

Among flowering plants, as you know, there are instances of geographical distribution quite as remarkable. Looking at Grisebach's work the other day, I observed, among the Orchideæ, *Phajus grandifolius*, unmistakably a native of the mountainous parts of Jamaica, also "a native of tropical Asia to Hongkong." And taking up Gray's Manual, to determine, for a young friend, the perennial herb *Phryma leptostachya*, common in our woods, we found the remark: "Also in the Himalayan Mountains."

On the whole, therefore, is it not still to be proved that *Rosa laevigata* is not a native of the south-eastern United States, as well as of the region corresponding in climate in eastern Asia?

Hope, Indiana.

F. R. Holland.

[Botanists have long held the opinion that the Cherokee Rose is not an American plant. Although thoroughly naturalized in some parts of the Southern States, it is not found remote from actual or ancient settlements, and the fact that it does not occur at all in the upper country, once the home of the Cherokee Nation, must dispel the belief that these Indians introduced it to the coast settlements. The fact that it has not become as firmly established in Jamaica as in the Southern States would be accounted for by the difference in the climate of these two regions, that of Jamaica even at high elevations above the sea being too hot for a Chinese plant. Is it not possible that a ship trading from China to Charleston, or some other American port, may have brought this Rose direct to this country, and that it may then have been taken to Jamaica from this country? Or it may have been introduced first into Jamaica and then brought to this country. *Rosa laevigata* seems to have been cultivated in England, however, as early as 1759.—ED.]

Recent Publications.

Flora of the Hawaiian Islands: A description of their Phanerogams and Vascular Cryptogams, by Wm. Hillebrand, M.D. New York: B. Westermann & Co.—This is a description in English of the plants of the Sandwich Islands, written by a German physician who resided on the islands during a period of twenty years, which were principally devoted to a critical study of their flora, although, having mastered the language, he practiced medicine in Honolulu with great success, holding besides several important offices under the Crown. The Hawaiian Islands are more remote from any continent than any group of similar extent; the character of their flora, therefore, and its relationship with other insular and with continental floras, are matters of extreme interest. As might be expected, the flora of these islands, in which "a single day's march will carry the traveler from the tropical heat of the coast to the region of perpetual snow," or where, by crossing an island, one may go from a climate with a rainfall of 180 inches to one of 30 inches, is rich in genera; and from their isolation especially rich in endemic species. Dr. Hillebrand describes 844 species of flowering plants, distributed in 335 genera, and 155 vascular cryptogams in 30 genera, making 999 species in 365 genera. Not less than 115 species, weeds in cultivation, escapes from gardens and accidental arrivals on the shores of the islands, have become fully established since these islands were discovered, and 24 species are supposed to have been introduced prior to the coming of Europeans. Eight hundred and sixty species, therefore, divided among 265 genera, or 3.25 species to one genus, are indigenous to the islands. Of these 860 species not less than 653 or 75.93 per cent. are endemic, 250 of these species belonging to 40 endemic genera. In the Hawaiian Flora are forms whose relationship can be traced to the plants of the South American continent, to those of Mexico and Australia, and to Polynesia. The shrubby *Lobeliaceæ*, of which there are four or five endemic genera, with fifty species, some of which are trees of considerable size, forming perhaps the most interesting and remarkable group of plants in this flora, have their nearest relatives in the South American Andes. The Australian flora is represented by Acacias and *Metrosideros*, the former quite Australian in their peculiar structure; while *Cytandra*, a Polynesian type, is represented on these islands by thirty endemic species. The most generally

distributed and the most valuable timber trees of the islands, although now fast disappearing of merchantable size, are *Metrosideros polymorpha* and *Acacia Koa*. The former, which is the most generally prevailing tree on the islands, between 1,500 and 6,000 feet elevation, produces a very hard wood, highly esteemed for fuel, and sometimes used in building. The *Acacia*, Dr. Hillebrand considers the most valuable tree on the islands. The wood makes excellent fuel, and is much used for building and for cabinet work, for which its beautiful grain well adapts it. It was from the trunks of this tree that the natives cut their great war-canoes. *Conifera* have no representative in this flora, a fact much less remarkable than that, besides the Coconut, there is but one genus of Palms (*Pritchardia*, a Polynesian genus of three species) with two species. Some interesting plants in the Hawaiian flora are a Dock (*Rumex gigantea*), with a woody base, which grows up among the trees of the forest to a height of forty feet; a Geranium, with a stout trunk, twelve feet high, and the shrubby or arborescent members of the Lobelia family, with fragrant flowers. Dr. Hillebrand, who left the islands as early as 1871, did not, unfortunately, live to see his book passed through the press, and his notes upon the distribution of species and the various aspects of the vegetation of this group of islands are left in a fragmentary and unfinished condition; and it is to his son, Dr. W. F. Hillebrand, of the Smithsonian Institute, that the last cares of publication have descended.

The "Outlines of Botany," written by Mr. Bentham, to precede the British and Colonial Floras, prepared in the herbarium of the Royal Gardens at Kew, is joined to the present work.

Periodical Literature.

Chambers' Journal for July contains an interesting article on "The Kola Nut," which is an abstract of an address delivered before the Fiji Agricultural Association, combined with extracts from Mr. T. Christy's book on "New Commercial Plants and Drugs." The tree which bears this nut is the *Sterculia acuminata*, a native of the west coast of Africa, between Sierra Leone and the Congo, and cultivated in the East and West Indies. It begins to bear in the fourth or fifth year after planting, but does not produce a full crop until it is ten years old, when its yield averages 120 pounds of seed. Two collections of seed are annually made, one in the autumn and one in the spring months. "When the fruit is ripe it takes a brownish-yellow color, and in this condition dehiscence of the capsule commences along the ventral suture, exposing red and white seeds in the same shell. . . . As many as five ripe carpels may result from a single flower and these may each contain from five to fifteen seeds; but in some cases carpels are found containing only a single seed. The seeds removed from their envelope weigh . . . from five to twenty-five or twenty-eight grammes. The epidermis is the principal site of the coloring matter, and beneath it is a tissue consisting of a mass of cells gorged with large starch granules, comparable to potato starch. It is in these cells that the alkaloids, caffeine and theobromine, are found in the free state."

In preparing the seeds for transportation, they are removed from their husks, freed of their skins, carefully picked over, and packed in large bark baskets lined and covered with leaves of Bol (*Sterculia heterophylla*). If these leaves are constantly kept moist and the seeds are picked over and re-packed about once a month, they may be kept in good condition for long periods, and are, in fact, thus transported from near Gambia and Goree to the Soudan or Timbuctoo, and thence to Tripoli or Morocco.

The value of the Kola nut is great, both as an article of food and as a medicine. It contains five times as much caffeine as tea and more even than coffee, and is a remedy for nervous complaints, heart troubles and digestive derangements. Prepared as chocolate, with sugar and vanilla, it is ten times more nutritious than cocoa, and the use now made of it in English hospitals confirms the verdict of the natives of west Africa, who are accustomed to depend largely upon it for subsistence in long caravan journeys. In the interior of the country it is so highly prized, that a dry powder formed from it is purchased by an equal weight of gold dust. Its uses here are not simply dietary, but, so to say, social. An interchange of white Kola nuts between rival chieftains means peace; of red ones, a challenge. Proposals of marriage are made with white Kola nuts, are accepted in the same manner, and refused with red ones. Oaths are administered by a person stretching out his hand over Kola nuts while he swears, and eating them immediately afterwards.

The Kola tree grows in low, damp or even marshy ground, and will flourish from the sea level up to an elevation of a thousand feet. Its cultivation is strongly recommended by Mr. Christy, as it is more easily raised than the Cocoa plant, and as the superior nutritive qualities of its fruit become better known, the demand for it rapidly increases.

Naudin, in the *Manuel de l'Acclimiteur*, speaking of the properties of the Kola, calls attention to the fact that it is often confounded with a false Kola called *Kola mâle*, or "Bitter Kola," which is produced by a shrub of the *Guttifera* (*Garcinea Kola*), which grows in the same regions. The mistake is often made by the natives, although the properties of the two nuts are quite different.

Recent Plant Portraits.

BEGONIA GERANIODES, *Bulletino de la R. Societa Toscana di Orticultura*, July; a white flowered South African species, of botanical rather than of horticultural interest.

SPATHOGLOTTIS AUREA, *Gardeners' Chronicle*, July 28th; from the plant which, under the name of *Spathoglottis Kimballiana*, recently received a certificate from the Royal Horticultural Society of London. "The cultural treatment it requires is much the same as that afforded to the genus *Bletia*, the material used in potting being turfy, yellow loam, peat and sphagnum moss, with a little silver sand added—the *Spathoglottis* being terrestrial plants. *Spathoglottis aurea* was first sold at Stevens' rooms by its importers, F. Sander & Co., in September, 1886, with a glowing, but it must be observed, an accurate description. It forms an admirable companion to the beautiful *Spathoglottis angustorum*, which is the same in general appearance, but white and rose, and the rather smaller bright Rose, *S. plicatum*."

CLEMATIS COCCINEA, *Revue Horticole*, August 1st; an admirable figure of this now well known Texas species.

Botanical Magazine, May, TREVESIA PALMATA, 7008; "one of the most conspicuous features of the tropical jungles of the Central and Eastern Himalaya, Assam, and the hot, humid regions of the Khasia Mountains and Chittagong, where its slender stem, crowned with terminal whorls of spreading, broad, fan-shaped, long-petioled leaves, rising above the herbaceous forest undergrowth, at once attracts attention." The greenish white flowers, in long peduncled panicles, are not showy, and emit a heavy, disagreeable odor.

ECHINOCACTUS HASELBERGII, t. 7009; a dwarf species of unknown origin, three inches in diameter, covered with slender spines, and producing small orange-red flowers.

SARCOCHILUS HARTMANNI, t. 7010; a delicate Orchid from the mountain forests of Queensland, with white flowers three-quarters of an inch in diameter, the sub-similar sepals and petals handsomely blotched with red near their base.

ARISTOLOCHIA WESTLANDI, t. 7011; a large-flowered species, native of southern China.

NARCISSUS PSEUDO-NARCISSUS, var. JOHNSTONI, t. 7012; a native of the neighborhood of Oporto.

HEUCHERA SANGUINEA, *Gardeners' Chronicle*, August 4th. STYRAX OBASSIA, *Gardeners' Chronicle*, August 4th; a well known and hardy Japanese species, and, so far as the foliage is concerned, the hardiest of the genus.

NEPHRODIUM TUERCKHEIMII, *Botanical Gazette*, t. II, July, 1888; a native of Guatemala.

CYRTOPODIUM SAINTLEGERIANUM, *Gardeners' Chronicle*, August 18th; "this may be regarded as the showiest form of the variable *C. punctatum*, from which it does not seem to differ in botanical features; it is, however, far handsomer than the general run of the species, and the bracts, which are highly developed, are barred and blotched with chestnut-red of the same bright hue as that seen on the yellow flower-segments."

STUARTIA PSEUDO-CAMELLIA, *Gardeners' Chronicle*, August 18th.

PROLIFEROUS STRAWBERRY, with flowers produced from the side, *Gardeners' Chronicle*, August 18th; an interesting figure as illustrating the true character of the strawberry, which is not a berry, as is popularly supposed, and not even a fruit, but the swollen and enlarged end of the flower stalk, the true fruit of the strawberry being the small dry stones, improperly called seeds. That the strawberry is really an enlarged stem the buds developed from the side of the specimen figured very clearly show. One of these is so perfectly organized that it has leaves, the commencement of a runner and a perfectly developed terminal flower.

SALIX PHYLICOIDES, *Botanical Gazette*, July, 1888; an Alaskan and East Siberian species of Willow,

Notes.

Apples are now being shipped from California to Australia.

The Japanese *Stuartia*, which is just now attracting attention in England, was exhibited in this city by Mr. Samuel B. Parsons as long ago as 1877. It was introduced into this country some time before by Mr. Thomas Hogg, to whom we are indebted for so many Japanese plants.

At the great exhibition of the Peninsula Horticultural Society at Wilmington, several fruit-growers made most attractive displays of the fruits of the entire season, the earlier ones being preserved by cold storage. Of Peaches, for example, the whole list was represented, from Amsden's June down to the very latest. The specimens were large and finely colored.

Mr. Thomas H. Douglas, Head Forester of the California State Forestry Commission, writes that *Catalpa speciosa* is very promising as a timber tree in San Diego County. The trees do well on sandy hills without irrigation, outgrowing even the Eucalyptus on such soil. *Catalpa bignonioides* is distinctly inferior wherever compared with *C. speciosa* in Southern California.

About two thousand acres of land are now devoted to Strawberry culture in the neighborhood of Centralia, Illinois, and from this point as many as 190 car-loads, or 2,097,600 quarts of berries have been shipped in a season of twenty days. The largest Strawberry field contains thirty acres, but the smaller ones pay better in proportion, and nearly every back yard in Centralia brings in pocket money.

Mr. Wm. Goldring, our London correspondent, has lately been commissioned by the Gaikwar of Baroda, one of the native princes of India, to design and carry out some important landscape works, consisting of gardens and pleasure grounds around his palaces and some public parks and gardens in other parts of his dominions. Mr. Goldring will spend the winter months for the next three years in India, and, in the course of his studies, will visit many of the notable gardens of that country. Descriptions of these gardens, together with notes on Indian horticulture and forestry, will be prepared by Mr. Goldring from time to time for GARDEN AND FOREST.

There now seems to be little question that an efficacious remedy for the Black Rot of Grapes has been found in certain preparations of copper sulphate. The experiments carried on under the direction of Professor F. Lamson Scribner, for the Department of Agriculture, have been characterized by great care and thoroughness, and if the results hoped for are realized, they will prove of incalculable value to all Grape-growers where the Black Rot and Mildew have been destructive. If this treatment will enable us to grow the varieties of *Vitis vinifera*, which has been impossible heretofore on account of these diseases, Professor Scribner's work will have a still greater practical importance.

Two years ago Mr. Carman, of the *Rural New Yorker*, succeeded in fertilizing the pistils of the Raspberry with pollen from the Blackberry, and planted the seeds which resulted from this union. Of the eighteen hybrids secured, three have fruited this year. One of them is a vigorous plant with large leaves, nearly thornless canes, and, to all appearance, a Raspberry with yellow fruit of medium size and of the quality of the Caroline. The second bears a red berry resembling the Hansell in size, color and quality. The third plant resembles a Blackberry, with flowers like those of a Raspberry, and bearing jet black berries with a Raspberry flavor. All the plants bear some imperfect berries, and, judging from their behavior this year, do not promise to be of much economical value.

The meeting of the Brooklyn Park Commissioners last week was invested with a peculiar interest from the fact that the advisability of engaging Messrs. Olmsted & Vaux as Landscape Architects Advisory came up for discussion. A letter from these gentlemen was read stating the conditions under which they are prepared to give their services to the Board in that capacity. It was urged by those who favored the measure that inasmuch as Messrs. Olmsted & Vaux were the original designers of Prospect Park, it was fitting that when \$200,000 are to be expended for its permanent improvement, these artists should be consulted as to the development of the plan. Dr. Storrs expressed the views of the Commissioners who appreciate the value of special training

when he said that they clearly needed the counsel and advice of men who have given their lives to the study of this kind of work. The matter was laid over until a future meeting, when a definite form of contract will be presented for acceptance. Some difference of opinion was manifested, and the final decision of the Board will be awaited with interest.

The current number of the *Art Review* contains an article by Mr. George Forbes, called "The Picturesque Adirondacks," which is well adapted to convince readers who have never visited this region of its great value to the people as a sanitarium in the widest sense of the word—as a place of recuperation and refreshment for body, mind and soul. As his title indicates, Mr. Forbes's aim is to disclose the beauty of the Adirondack country rather than its economic value. It is not his purpose, he explains, to inquire into the matter of its "prodigious importance as the ultimate source and reservoir of the water-supply of the State, and into the corollary question of its Forestry-laws." Yet he cannot refrain from asking whether, even if "its æsthetic charms" were alone in question, they do not "demand a legislative enactment that shall make the entire section a State Park, as free to the people of this and other States as are the Niagara Falls Reservation and the Yellowstone National Park?"

The *Weekly Press* (Philadelphia) has been collecting through its correspondents some interesting data as to big trees in various parts of the country, and measurements of remarkable trees in fourteen states are published in the number for August 22d. Among these are a Live Oak in Marion County, Florida, with a trunk circumference of thirty-one feet, and a spread of branches of nearly 139 feet; a Sugar Maple in Bradford County, Pennsylvania, with a girth of sixteen feet, and branches spreading eighty-three feet; an Elm in Shinnston, West Virginia, with a girth of twenty-seven feet three inches, a spread of branches of 123 feet, and a total height of 110 feet; a Chestnut in Lancaster County, Pennsylvania, with a circumference of twenty-five feet three inches, and branches spreading eighty-eight feet; a sycamore in Wabash County, Illinois, with a girth of twenty-eight feet, and a Sassafras at Johnsville, Pennsylvania, with a circumference of thirteen feet six inches three feet from the ground, a spread of branches of thirty-five feet, and a total height of forty-six feet.

At the Sixtieth Annual Exhibition of the Massachusetts Horticultural Society last week the display of out-door flowers was not so large as usual, owing to the protracted rains, but the quality of those shown was of the best, and the arrangement of the cut flowers and green-house plants was better than usual. Fruits were exhibited in great profusion, although Apples and Pears were not so abundant as in former years. They were exceptionally free, however, from fungus and blight. Vegetables were shown in great abundance and variety and not a single poor specimen was seen, and the fifty dishes of perfect Tomatoes placed together presented a mass of color unequalled in the hall. Among the ornamental plants, the collection of Orchids and green-house plants contributed by Messrs. Pitcher and Manda, of Short Hills, was noteworthy. A magnificent specimen *Latania Borbonica* from Mrs. Francis B. Hayes was conspicuous in the upper hall. Mr. L. W. Goodell made an attractive exhibit of *Nymphæas* and other water plants, and a fine specimen of *Nepenthes* with twenty pitchers was sent by George McWilliam, gardener to Mrs. J. Lasell. A great group of green-house plants from Mr. Nathaniel T. Kidder contained the six specimens for which the prize was given to his gardener, William J. Martin. Thomas Clark, gardener to Mr. Brooks, showed, among other fine plants, a *Cibotium princeps* which took the first prize for a Tree Fern, and A. J. Wheeler, gardener to Mr. J. H. White, contributed an admirable collection, including an *Acalypha* of remarkable color. A collection of native flowers from Mrs. P. D. Richards was one of the most interesting features of the display, and Mr. James F. C. Hyde sent thirty-eight varieties of cultivated native Asters, two of them cross-bred seedlings, and a large and finely colored *Gentiana Andrewsii*, which he had cultivated. An instructive collection of plants, ornamental and useful, came from the Harvard Botanical Gardens, including specimens of the Olive, Logwood, Coffee, Pepper, Papyrus, Cinnamon, Mahogany and many more. The value of this collection was greatly increased by the complete and accurate labeling of the plants. Among cut flowers, the new Rose, Madame Watteville, was shown by Norton Brothers, some of the best new Cannas and tuberous-rooted Begonias by Edwin Fewkes & Son, and well-grown Dahlias by Edwin Sheppard, John Parker and George S. Tuttle.

The Artistic Aspects of Trees:—IV.

FORM, texture and color—these we have noted as the three qualities to be considered when trees are studied for their artistic value.

If, in ornamental planting, we used only the materials which nature supplies in the neighborhood of our homes, no one of these qualities would seem of more interest in the planter's eye than the others, or would offer him more chances of making mistakes. But, as a result of the efforts of generations in introducing exotic species of trees and in perpetuating casual natural eccentricities as well established varieties, color has been brought into greater relative prominence in the nursery than it assumes in nature's workshop. The planter is therefore more apt to be struck by varieties of color than by those of form and texture; and as a rule thinks more of the effects which he can produce with them, and commits with them his most frequent and conspicuous mistakes. If a true artist could always be employed when a work of landscape gardening is in question, then the development of our numerous and striking nursery varieties of color—which include tones of purple, red, blue, white, and especially yellow in a score of different degrees, and many striped and mottled effects as well—might be counted wholly fortunate; for, of course, the wider the range of an artist's palette, the more numerous will be the kinds of beauty he can produce. But color is the most difficult of qualities to manage, the most revengeful when managed wrongly; and, in the hand of the ordinary planters the varied material of to-day means merely a greater confusion of tints, a more painful degree of unrest, spottiness and ugliness, than would have been achieved had the materials from the neighboring woods been adhered to. Too often, in small grounds especially, it seems as though the aim had been to do away as far as possible with medium green tones and to set upon a carpet of vivid emerald turf as many trees of strong eccentric hue as could be collected. Even when the general tone of the landscape is pretty well preserved and bright or variegated trees and shrubs are used simply as accents here and there, too little thought is given to placing them where they will be emphatic yet not disturbing, too little to the

question of their beauty as distinct from their mere novelty or eccentricity. As a rule it is better to avoid striking colors altogether and keep to the quiet medium tones of green. These offer variety enough to satisfy a cultivated eye in the majority of cases; and if an emphatic note is really needed, it can be supplied, where the general effect is softly harmonious, by means of something less brilliant than a Golden Poplar or a Purple Beech. Such trees as these have their place in gardening art; but an amateur's eye is hardly the one which can be trusted to find it. For the amateur, in short, the safest course is the best one to follow, although it may not be the one which an artist will always follow in his search for the highest and most individual kinds of beauty. If a dull tree stands where a bright one would have produced a better effect, we may feel that a chance has been missed. But if a bright one stands where harmony required a dull one, then we feel that an actual sin against good taste has been committed.

The art of the gardener has likewise greatly increased variety in the forms and in the textures of trees, giving us pyramidal and weeping shapes, and finely cut or fringed foliage, in a perpetually increasing flood of "novelties." Here again the amateur is apt to be seduced into thinking that novelty means excellence, that eccentricity means charm; is apt to plant what he selects without regard to harmony of general effect, and to select in the interests of curiosity rather than of a love for genuine beauty. And here again it may be said that the safest course is the wisest one to follow. Normal shapes can hardly be so distressing, however they may be combined, as abnormal ones are sure to be if there is the slightest error in their combination.

Of form it may, furthermore, be said that a tree is not well understood until it is understood in all the stages of its growth. The typical shape of a young tree often differs very greatly from the typical shape of the same tree at maturity, and this again from its typical shape in old age; and, in planting, regard must be paid to the question whether an immediate effect or a long-postponed effect ought to be most considered. For example, a tree set in isolation on a lawn in full view from the house ought to be beautiful in youth and at the same time give promise of beauty (perhaps of a different kind but still appropriate) in later years; whereas in planting a belt or wood in the distance, the principal trees should be so chosen that they will look better and better the older they grow, while present effect may be chiefly considered in others which are destined to be cut as development progresses.

Texture varies less with the passage of years than form. Color is practically persistent year after year, but varies from month to month; and this fact should also be borne in mind. There are some trees, like the Yellow-wood, for instance, which are of a medium tint in the middle of summer, but of a yellowish green in spring, and it is unwise to place them where during a few weeks they will not look well, even if later on they assume a harmonious hue. Autumn effects should also be more carefully considered than they are; but to speak of the possibilities which are open to an intelligent planter in this direction would require a long chapter instead of an incidental paragraph.

Large Palms and other tropical plants grown in tubs or large pots are now often used in this country for the decoration of the lawns of country places or of some of the fashionable cemeteries, where costly glass-houses are maintained on purpose to store these plants in winter. No system of garden-decoration is more expensive, while few of the devices of modern gardening are more displeasing or unsatisfactory in their results. Palms, with very few exceptions, when placed out-of-doors in this climate soon become shabby; the foliage is torn and injured by the slightest storm, and having been produced in a damp and shaded atmosphere, soon turns yellow when exposed to the full blaze of the sun. But the most perfect specimen looks out of place on one of our northern lawns. It injures

the appearance of the trees and shrubs with which it is thus brought in contact, while these quite destroy the beauties of the Palm. Contrast of this sort is not beauty, and the result must always be unfortunate. Such plants have no place in the cemetery; and the money they cost could be directed with greater advantage in caring for hardy trees, and for the grass, which is too often neglected in such places. In private gardens they are appropriate and splendid objects for the summer-decoration of protected terraces and piazzas, as their graceful lines harmonize always when brought into close connection with architecture; but the true way to enjoy Palms and many other plants as well in this country is in a summer conservatory or tent, which can be spread over a terrace or a portion of the lawn in immediate connection with the house. Such a tent can be made to supplement the house in a delightful manner, forming an out-door apartment in which Palms and other foliage plants will thrive, and in which many flowers show their greatest beauty. Such a tent can be made attractive here during five months, and in such tents the tropical plants which are now allowed to disfigure, during the summer, many a fair scene should be gathered for their own and for their owners' good. But incongruous and out of place as Palms look in an American landscape, the effect produced by planting Agaves, almost universally called Aloes here, upon the turf of a lawn, is even worse; and when a number of these plants are packed close together in a circular bed the effect is grotesque beyond description. These, of all plants, are the most architectural in outline. Naturally they grow in a country and in situations so dry that there is never a vestige of grass near them. Standing out among the dry, bare, sun-scorched rocks of the Mexican mountains, they are often beautiful objects, filling the traveler with amazement and delight; but an Agave growing out of a trimly-mown lawn of grass is something which the imagination of a person who had only seen these plants as nature displays them could never picture. But they have their use in our modern gardens. No other plant can so appropriately or handsomely decorate the balustrade of a terrace or the steps of a great building. Whenever they can be used directly in connection with buildings they are in the right place. No other plants which can be properly used in such situations can so well support the heat and drought which full exposure to the sun entails, and there are no plants which, when used in such situations, give such universal satisfaction. It is evident that the decoration of gardens can never attain to its greatest possibilities until plants are more generally studied than at present in their homes, and in special relation to their natural surroundings.

Central Park, Minneapolis.

WHAT is now Central Park, Minneapolis—a pleasure-ground for pedestrians only, of some thirty acres in extent, in one of the best residence quarters of the city and surrounded by costly houses—was, no longer than four years ago, a piece of low, undrained pasture land. On one side of this pasture was a pond-hole, perhaps a hundred feet in diameter, surrounded by a broad margin of bogs, and from this the water oozed through marshy ground, over which it was hardly possible to walk dry-shod at any season. Upon the area through which the pool found its outlet, as well as upon its borders, there was neither tree nor shrub until three years ago, when the park planting was begun, and the swift transformation which has been effected here can be partly understood from the illustration on page 379, which gives a view of a portion of this marsh as it now appears. The pool and bog were excavated to form a lake, four acres in extent, and some of the earth was used to construct in it an irregular island. In addition to the natural springs found here, an artesian well was sunk from which three hundred gallons of pure water are delivered every

minute, so that the lake is well supplied with living water. That no hint of artificiality appears, however, either in the island or the lake, can be well imagined from the natural treatment of the shores, as seen in the illustration.

The view is taken from a point on the lake-shore opposite to the lower extremity of the island, and looking through a narrow channel between the shores of the island and the lake, with the island on the left. Above the island the opposite shores of the lake approach each other until they are near enough together to be spanned by the bridge shown in the illustration, while the larger portion of the lake lies still beyond. The shrubs, which are massed so effectively on either shore, were taken from neighboring swamps and woods three years ago. Conspicuous among them is the Red-berried Elder, whose arching branches admirably fit it for a position on the border of the water. Among other shrubs which overhang the lake are Sumachs and Red-twigged Dogwoods, while further back are Snow-berries, Button-bushes and other wild shrubs. The tops of distant trees, which form a portion of the sky-line, are on the further shore of the lake. These trees were also taken from neighboring woods, and, although they were large specimens, they have been so well cared for that their growth, like that of the shrubbery, has been exceptionally strong. When it is considered that artificial lakes and islands are always counted difficult of construction if they are to be invested with any charm of naturalness, the success of this attempt will not be questioned, while the rapidity with which the artist's idea has grown into an interesting picture is certainly unusual.

This park was designed by Mr. H. W. S. Cleveland.

On a Sand Ridge in California.

ONE day, about the first of June, 1888, I wandered in search of wild grasses to the summit of one of the foot-hills of the Santa Cruz range of mountains, some six miles back from the coast. It was a sandy hill, seemingly barren, but rising out of the white earth were many plants, undoubtedly natives, in the full glow of summer growth. This ridge, and in fact most of these mountains, are composed of sandstone, shale, and diatomaceous earth—a stratified oceanic deposit. Here we find fragments of shells, bits of bones of marine mammalia, teeth of sharks, fragments of echinoderms, etc. In the shale, or "chalk rock," as it is commonly called, are immense quantities of a few species of diatoms, and spicules of sponges. There is enough lime, magnesia, and the like, to act as a slight cement in holding the particles together. Some of the "shale," however, has a flinty hardness, and looks much like flint. It contains some silex and aluminum.

There are numerous perennial springs of cold water among these hills. In some places there are bituminous oozings, and occasionally a mountain-spur of sandstone completely saturated with asphaltum. This material is used quite extensively now for covering the streets and sidewalks of our towns and cities. It answers an excellent purpose, because it is indestructible, and a good material to walk or drive over.

Wherever there are valleys or basins there are trees of all sizes, and many species, from the Manzanita, four or five feet high, to the tall Redwood, 100 to 200 feet high. Geologically all this region belongs to a comparatively recent period. The fossils are mostly of the same species as those now living in the Bay of Monterey.

Of the plants growing on this apparently barren sand ridge I might make a long list—much longer than would at first seem possible. Within fifty steps of where I stood on the summit of the little sand ridge I noted with my pencil about twenty-five species. I did not stoop to examine the smaller kinds.

I will mention a few of the most attractive. A species of *Ceanothus* (*C. cuneatus*), or "Lilac," as it is known in

California. It is a very pretty spreading shrub, six to eight feet high, with smooth, thick, reticulate-veined leaves, one-half to one inch long, often with a notch at the apex, darkish green above and glaucous underneath. The flowers are in globular clusters about one inch in diameter, white or pale blue, and fragrant. When in bloom it is a charming shrub as it grows on these hills. Another bush touching the Ceanothus is a Manzanita (*Arctostaphylos tomentosa*). It is an evergreen and exceedingly variable plant, no two being of the same color of foliage. Chameleon-like, it varies with season, locality and stages of growth. Its dark reddish trunk (most frequently in clusters) is always gracefully crooked and ornamental. In June the flowers have all disappeared, and the little berries, one-fourth to one-half inch in diameter (little apples, their name signifies in Spanish), green, red and brown in color, hang in pretty clusters among the old and new leaves.

In such places the California Poppy (*Eschscholtzia Californica*), is seldom wanting, and it was present here with its inimitable yellow flowers on long stems, which generally find support among the branches of some dwarf shrub, such as the Chamisal (*Adenostoma*).

I found here, also, a very pretty Cichoriaceous plant in full bloom (*Malacothrix obtusa*), with its radical leaves spreading on the clear sand, and scape-like, branching stems bearing beautiful yellow flowers, next in richness to the Poppy. I brought home some of these, which continued for two weeks to open out each day and close at night their pretty flowers.

Among the several grasses I will mention the one most prominent; a beautiful and stately Blue grass, *Poa tenuifolia* of Nuttall. It is beautiful because so unexpected and out of place in such a locality. Growing in bunches, two or three feet high, with numerous slender, often purplish leaves, it tempts one to try the experiment of planting a lawn, or making a Blue Grass farm on some of these sand ridges! More improbable things have been done; for instance, in Golden Gate Park, in San Francisco, where roving sand hills and Alaska winds have been tamed down to gentle slopes and genial breezes, by the aid of certain trees for wind-breaks, and a skillful selection of other plants adapted to the holding of the sand and staying the air currents.

At present our sand ridge only serves the slightly useful purposes of keeping pure the native plants, of storing up some heat from the sun during the day to temper the night breeze, and producing a few mouthfuls of forage for grazing cattle.

What its full capabilities are, must remain for future experiment. It is certain a vineyard can flourish there, for that has been demonstrated near by. Some day probably certain forest trees may grow on these sand slopes, to supply timber for future generations, to preserve and equalize the water supply, and to protect orchards and farm-lands from the too violent sweep of winds that sometimes blow from the north and west.

Santa Cruz, Cal., July, 1888.

C. L. Anderson.

Foreign Correspondence.

London Letter.

THERE was an abundance of flowers to-day, for the most part from the open air, at the meeting of the Royal Horticultural Society, and the unusually large number of first-class certificates awarded is proof of the excellence of the novelties. The chief feature of the exhibition was a magnificent display of Gladioli from the famous growers, Messrs. Kelway, of Langport, in Somersetshire. I do not know whether *Gladiolus Gandavensis* is grown much in America, though I imagine that they could be grown to perfection in your hot summers. If they are not, they should be, for there are few flowers that can surpass the splendor and the stateliness of a perfect *Gladiolus*, such

as James Kelway can produce. Of the 500 spikes displayed not one was under eighteen inches in length, and every one carried a score or more of expanded flowers and buds, every flower being three to even four inches across, as perfect in form as the most exacting florist could desire. The colors of these Gladioli have an extremely wide range, showing every gradation of tint, from the most glowing scarlets and crimsons through the most exquisite shades of pink to the purest of whites. Some are penciled, lined, flaked and blotched in the most subtle way, and all have their petals of wax-like texture, the crystalline cells of which sparkle on their surface like gems. This is not an overdrawn picture of what Kelway's Gladioli are to-day, and I thought, when admiring them this morning, how odd it is, not to say perverse, that flowers of such marvelous beauty should be neglected because their market value is not so great as that of Orchids and other expensive tropical flowers. Of the hundreds of spikes shown to-day the majority represented old varieties, but a large number of new seedlings were shown for certificates, and of these the Committee selected the following six sorts: Cebes, brilliant cherry-crimson, quite a new tint; Magas, white, delicately penciled with pink; Micon, upper segments blush white, flaked with pink, lower segments pale primrose-yellow, a distinct break in color; Accia, vivid scarlet, with lower segment white; Bullion, pale yellow, flaked delicately with carmine, and Mago, carmine-crimson, with white lower segment. All these have massive spikes and large flowers of perfect form. Others could have been chosen that worthily deserved a like award, but the principle is not to be too lavish with certificates. For the next two or three meetings Messrs. Kelway will show an array of Gladioli such as this from their broad acres at Langport.

Double Begonias, from Messrs. Cannell, of Swanley, were another feature to-day. A large group of new seedlings were shown, all with flowers as double, and, in many instances, as large as good double Hollyhocks, but only two were chosen for certificates; one, named Mrs. Lynch, with rosetted flowers, four inches across, of a clear rose-pink, and Mrs. Lascelles, very large and double, pale cherry-carmine. These both have vigorous growth and good habit. From Swanley also came some new single Begonia, and the Committee found themselves bound to deviate from the usual rule in not certifying seedling single Begonias for the sake of one called White Lady, whose flowers were of such faultless shape—that is, they were almost, if not quite, circular, and of snowy whiteness—in fact, it is one of the best, if not the purest, white single Begonia yet raised. Among the others were some with orange-red or flame-colored flowers, which were very showy.

For the first time this year Messrs. Cannell sent a selection of the splendid new varieties of Canna, to which I have referred in one of my former letters. Those shown made an exceedingly fine display, and the large, bold-looking foliage, like small Banana-leaves, seemed to set off the glowing colors of the flowers to great advantage. The curious, unsymmetrical form of Canna flowers adds to their beauty, and the uninitiated public look upon them as Orchids. Four Cannas, the pick of a large group, were certificated. These all rejoiced in French names, thus indicating their origin. Admiral Courbet has large flowers, with bright yellow petals, heavily and profusely blotched and spotted with blood-red; Capricieux has flowers with bright orange-red petals, conspicuously and prettily edged with golden-yellow, a most striking sort; Francisque Morel has flowers of a deep crimson, and Madame Just I should describe as nankeen color, it being that peculiar mixture of red and yellow that nobody can intelligibly describe. To these four I should have added one called Felix Crousse, also with singular orange-red flowers. These hybrid Cannas are unquestionably the coming flowers, as they are invaluable for winter bloom. With a little management they can be made to bloom in summer and winter continuously. At Swanley they are grown in an

intermediate temperature, planted out in free soil in a long, narrow, span-roofed house.

Dahlias have made their first appearance at the meetings, and for the next two months we shall be surfeited with novelties among them. To-day there were many new sorts put before the committee, but very few were considered good enough for a certificate. In my estimation the finest sort, and one that will prove of most value in the garden because of its distinct color, is one called Beauty of Brentwood. It belongs to the so-called Cactus Dahlias, and has flowers of the same size and shape as *D. Juarezii*, but the color, instead of scarlet, is a beautiful shade of carmine, or perhaps some would say, carmine-magenta. It is certainly a most telling flower, and one that will make its mark. It received a unanimous vote. Two single Dahlias from Messrs. Cheal, of Crawley, won certificates. One was Victoria, with white florets edged broadly with deep red, the other with broad flat florets of a pale pink edged with buff—a most strange combination of colors, hence its value as a break; but as it only won a certificate by a majority of two votes, you may glean that it did not please every one.

The pretty little white *Campanula isophylla alba* was awarded a certificate. It is not a novelty, but was particularly well grown and flowered. It is a beautiful plant for a suspended pot in a green-house or window, but is not quite hardy in England in the open air.

Mr. B. S. Williams made a fine display of Orchids in flower, and one was singled out for a certificate. This was the rather rare *Odontoglossum Karwinskii*. It has a long flower spike, dull-colored sepals and petals, and a broad labellum colored with various shades of reddish purple, but it is not what one would call an attractive Orchid. Mr. Williams' group was rich in Orchids that flower at this season, the rarest among them being *Cypripedium Sanderianum*, *C. porphyreum tessellatum*, *C. Ashburtoniae*, var. *superbum* (new and beautiful), *C. Ashburtoniae expansum*, *Cattleya aurea*, *Pachystoma Thompsonianum* (a great rarity and very pretty), *Cattleya Eldorado alba* and *splendens*, *Cypripedium ananthum superbum*, *Dendrobium Goldiei*, all of which are worth making a note of as being among the finest of the comparatively few Orchids that flower in the latter half of August. Two new Maidenhair Ferns were shown also by Mr. Williams. One was *Adiantum calpodis roseum*, which has its young fronds of a coppery red hue, the other a crested fronded variety of *A. Capillus-Veneris* named *A. Versaillesense*, a crested, parsley-like Fern. This was awarded a certificate, but the vote was not unanimous. One of the several new varieties of Delphinium shown by Messrs. Kelway won a certificate. It is called Horus, and has a massive spike of large flowers, deep indigo blue, centered with white.

London, August 24th

W. Goldring.

New or Little Known Plants.

Rhododendron (Azalea) Vaseyi.

AMONG the additions which have been made of late years to the Flora of the United States, few plants have a greater scientific and horticultural interest than the beautiful *Rhododendron* figured upon page 377 of the present issue of this journal. Its nearest American ally is the *Rhodora*. In eastern Asia, however, there are two or three species of *Rhododendron*, with the campanulate, irregularly bilabiate corolla which characterizes *Rhodora* and this species, which is very like the sub-alpine Japanese, *R. Albrechtii*. The discovery, therefore, of *R. Vaseyi* added, as Professor Gray at once pointed out, "another to the now very numerous cases of remarkable relationship between the China-Japanese and the Alleghanian floras." *Rhododendron Vaseyi* has been so fully described, that it is only necessary to add to Professor Gray's and Mr. J. Donnell Smith's remarks* upon this plant that Mr.

**Rhododendron Vaseyi*, A. Gray, *Proc. Am. Acad.*, xi. 48; *Bot. Gazette*, viii. 282.—John Donnell Smith, *Bull. Torrey Bot. Club*, xi., 364

Faxon, from whose drawing our illustration is made, notices that the upper or posterior lobe of the corolla is exterior in the expanded flower, a peculiarity we have been unable to detect in the flowers of any other *Rhododendron*.

R. Vaseyi is a tall shrub with slender branches, fifteen to eighteen feet high, with bright, clear pink, precocious flowers, marked towards the base of the upper lobes of the corolla with numerous darker spots. They are quite unlike in color, and appear much earlier than those of other American Azaleas. *R. Vaseyi* was discovered by Mr. George R. Vasey, in 1878, near Webster, in Jackson County, North Carolina; it was afterward found in Cashier's Valley, South Carolina, directly in the rear of the house long occupied, during the summer months, by the Hampton family, where it grows in great luxuriance with *R. arborescens*, occupying the low banks of a small stream; and during the present season it has been found again, this time by Mr. S. T. Kelsey, upon Grandfather Mountain, in North Carolina, only two or three miles from Louisville, "growing everywhere in clumps and patches on the southern and south-eastern slopes, at 4,500 to 5,000 feet elevation, but most abundant and vigorous in moist situations, and is associated with *R. maximum*, *R. Catawbiense* and *Kalmia latifolia*." *R. Vaseyi* takes readily to cultivation, flowering freely when not more than a foot high, and promises to be perfectly hardy in the climate of Boston. C. S. S.

Kœlreuteria bipinnata.

MONSIEUR FRANCHET contributes an interesting account, accompanied with an illustration of the new *Kœlreuteria* of western China, to a recent issue of the *Revue Horticole*. It is one of the most important, from a horticultural point of view, of the numerous discoveries of the French missionary, Delavay, who alone, and remote from all Europeans, has been able in the short space of four years to double the number of Asiatic species of certain genera. The field of his observations is a very limited one, not many square miles in extent, yet he has detected in this small region of the mountains of Yunnan no less than thirty-two new *Rhododendrons*, and as many new Primroses and Gentians.

Kœlreuteria paniculata is a well known, small, ornamental tree from northern China, with large compound leaves, consisting of from six to ten pairs of leaflets and large panicles of yellow flowers, which appear in July. "The new *Kœlreuteria*," Monsieur Franchet points out, "is entirely distinct, as may be judged from the following description:

"*Kœlreuteria bipinnata*, Franch., *Bull. de la Soc. Bot. de France*, xxxiii., 436, t. 93. A very vigorous tree, sixty feet high; leaves twenty-six inches long by twenty-four inches broad at the base, doubly pinnate; pinnæ coriaceous, alternate, distinctly pedicelated, nearly glabrous, dark green above, pale on the lower surface, oval-lanceolate, sharply serrate. The flowers resemble those of *K. paniculata*; they are bright yellow in color, the narrowed base of the petals purple, and are produced in enormous, compact panicles. The capsules are broadly oval, always obtuse, sometimes nearly round, two and a half inches long, turning purple when fully ripe. The seeds are black, the size of a small pea.

"*K. bipinnata*, grows in the forest of Ta-ling-tin, above Tapin-tza, in central Yunnan, at an elevation of more than 5,000 feet. It flowers at the end of July, and the fruit is ripe in the autumn.

"It is a remarkable tree on account of the size of its leaves and the abundance of its flowers. In the autumn its appearance is unique with its immense panicles of large purple pods. It is probable that this new species will grow in cultivation as freely as its relative, but the experiment has not been tried yet. The seed germinates freely, and the young plants grow rapidly. Even if the climate of Paris should prove too severe for this tree, it will no

doubt thrive admirably in western and central France."

The climate of Yunnan is probably not very unlike that of the mountainous portions of the southern United States, and there is a probability that many of its plants will grow in the climate of our Middle States, if not further north on the Atlantic seaboard. One of the most interesting of Monsieur Delavay's discoveries is a large evergreen Magnolia, almost identical with *M. grandiflora* of our Gulf States. The behavior of this tree in cultivation will be watched with the greatest interest, as it may be expected to prove much hardier than the American species, which is confined to the sea-coast, and never extends into the mountains, or even the upper middle districts. C. S. S.

Cucumbers, Egg Plant, Peppers and Squashes are vegetables that will suffer from the slightest frost. Cauliflower, Brussels Sprouts, Celery, Spinach, Parsley, Peas, Lettuces, Endive, Beets, Carrots, Turnips and Radishes are not injured by slight frosts. But do not handle these crops in frosty weather, no matter how hardy they may be. Have frames, sashes, plant-cloth lights, sheeting, mats or other protecting material at hand for use in case of need. Heavy or cold rains are injurious to Cucumbers at this time of year, therefore it is well to keep covered with sashes all the time and tilt these up a little in the warm part of the day. If any gaps occur in recently sown Spinach rows seed can still be sown in the vacant spaces. The recent heavy rains have packed the soil so firmly, and, in many cases, buried the seed so deeply in the ground, that it has rotted. Have a good stock of young seedling Lettuces to prick off thickly into frames, and half grown plants with which to fill up the frames for winter. Earth up the Celery that is to be used before New Year's, a little at a time, and always in dry weather and when the leaves are perfectly dry; and "handle," that is, draw some earth in around, the late Celery, so as to give the heads a compacted rather than spreading form. In earthing up, pack the earth firmly around the heads so as to exclude water from running down and settling among the leaf stalks. Keep root crops clean and keep the hoe at work among the young Beets, Carrots and Turnips, but do not lift any of these for storing before there is danger of hard frost—that is, about the middle of November here. Gather Squashes under cover in an open airy place where they will be free from frost. Have the Potatoes in a dry, cool place, but where the frost cannot reach them and where it is dark enough to prevent the tubers from becoming green. If cellar room is lacking, Potatoes may be stored in pits out-of-doors, but the pits should be shallow, well ventilated, and covered thinly at first, and so arranged that water will readily drain away from them.

Clear away all dead, dying or spent vegetables, and keep the Melon ground clean from decaying fruit. Melon vines and Potato and Tomato vines should not be thrown into the hog pens, but should be wheeled to the rot-pile, as a foundation for compost; but old Cabbage, Cauliflower, Lettuces, Beans, and all other vegetable matter which pigs are fond of, and which decays quickly, can be thrown into the pens with much benefit to the animals and capital returns in the way of a mass of rich manure. In cutting over Asparagus in November, burn the old stalks to destroy the beetle as far as possible.

Glen Cove, N. Y. Wm. Falconer.

Autumn Apples.

FOLLOWING closely the early Apples named in a previous article comes Maiden's Blush, a very handsome

Apple, with a waxen skin and a blush that any maiden might envy. The tree is a good grower and yields well; the fruit is generally smooth and perfect, fine for dessert or cooking, and keeps in good condition longer than the earlier sorts. I have kept specimens till January, but only as objects of curiosity, as they lose their flavor after a time. Another fine Autumn Apple, though of an entirely different type, is the Gravenstein, a handsome red striped Apple, of larger size and higher quality than the Maiden's Blush.

The Porter represents another type, being a conical golden yellow Apple, of fair to large size and excellent quality. The tree is an abundant bearer, though hardly as vigorous in growth as the two last named. Its season is from September to October.

The Fall Pippin, when in perfection, for size and excellent

Fig. 60.—Rhododendron (Azalea) Vaseyi—See page 376.

Cultural Department.

The Vegetable Garden.

CONTINUED wet weather has caused rank growth in Celery, Cauliflower, Beets, Turnips, and other young crops, and an unusual plumpness in Snap and Lima Beans, and vigor in Corn, but it has been very detrimental to Tomatoes and Melons, causing them to ripen slowly and with a marked tendency to rot. In fact, the whole season has been irregular and backward with several crops. A fair crop of Globe Artichokes is usually due in September from plants raised from seed in early spring, but this season, so far, only two plants among sixty have produced heads.

Prepare for frost. Tomatoes, Snap and Lima Beans, Corn,

quality is, unquestionably, queen of all the autumn Apples with which I am acquainted. The tree is of spreading habit and good growth, but it does not bear as early or abundantly as the trees already named. The fruit, too, is liable to apple scab, which mars its beauty. Fifty years ago it was grown extensively in this vicinity under the name of the Vanduyne Apple, and I can remember earning my first money with other boys who were employed, at fifty cents a day, to hand-pick the Apple crop of a neighbor and pack the Apples in single-headed barrels, for carting to New York. But the old trees have disappeared, and now it is difficult to find a tree of mature age. Nevertheless, the excellence of the Fall Pippin should insure a place for one tree in the smallest collection of autumn Apples.

A strong competitor of the Fall Pippin is the Orange Apple. The tree is a better grower and much more productive. The fruit is nearly or quite as large, on the average, and fully as handsome, being really "Apples of Gold," smooth and fair to look upon. When first ripe they are a trifle too acid to suit some tastes for dessert use, but when they become mellow the acidity mellows, too, into a most agreeable flavor. This is at all times an excellent cooking Apple and eagerly sought for by all who know it. This Apple has been confounded with the Fall Orange of Massachusetts and the Lowell or Greasy Pippin, which Mr. Downing records as distinct from the Orange, although this name is sometimes given to it. There is also an Orange Pippin grown quite extensively in New Jersey which I think is different, but I am not so familiar with it that I can assert this positively. The Orange Apple, according to Mr. Downing, originated in this State, and is emphatically a New Jersey Apple; in fact, I do not remember of meeting with it elsewhere. Its season is from October to December.

E. Williams.

Montclair, N. J.

Cannas.

EHEMANN'S *Canna* surpasses others in its magnificent proportions, and in the abundance and persistence of its elegantly disposed, showy flowers. No other plant in the garden displays as great luxuriance in one season's growth. For a mass of it here, twelve feet by forty-five, and now impenetrably thick, and grading from five feet high at the outside to nine feet high in the middle, the plants were set out April 30th, singly, and twenty-four by thirty inches apart, in rich ground. They made very little fresh growth before June, but since then they have grown amazingly, and have been continuously in bloom since early in July. I have never known this *Canna* to mature seed. When set out the plants consisted of one to three shoots each, and now they show from five to eleven stalks to each clump. Last fall, when it was touched by frost, I cut it over at the ground, and, in order to secure a large stock, at once divided the crowns into as many pieces as there were eyes, and these were planted quite close together in a frame heated in winter by a hot water pipe enough to keep frost out, and were left there till planted out. While they were in the frame their leaves were cut back two or three times before planting-time, as they were growing up against the glass, but it did them no harm, and when the plants were set out they were fairly well rooted. All new and rare *Cannas* can be treated in the same way.

The old forms, such as *Warszewiczii*, *Discolor*, and the like can be stored on a dry shelf in the cellar, and left there from November till April unmoved, but we cannot keep *Canna Ehemanni* in that way. It will not bear to be completely dried off with impunity, nor will *Canna flaccida*.

Premices de Nice is the best tall-growing, yellow-flowered *Canna*. It bears branched spikes of clear yellow blossoms that rise well above the foliage. *Nouttoni* forms a grand companion plant to Ehemann's, but it does not grow so tall nor has it such massive foliage. Its flowers are large, showy, and of a rich crimson color. Adolph Weick is another brilliant-flowered sort, but of more compact habit than those already mentioned. If fine foliage is desired more than blossoms we have nothing better than *Robusta perfecta*.

Within the last few years a new race of *Cannas*, popularly known as *Gladiolus*-flowered *Cannas*, has appeared. They are of quite dwarf or of moderate size, and have deep green, glaucous green, or bronzy crimson foliage. The flowers are unusually large and of many shades of yellow, terra cotta, orange, crimson and crimson-scarlet, and are really showy and beautiful. Emile Leclair is a good representative of this class. It has large, golden-yellow flowers, spotted with crimson and scarlet, and pea-green foliage.

In the great flower fields at Queens the other day I noted a large assortment of these handsome *Cannas* in bloom. Among them were:

Admiral Courbet.—Green foliage; flowers large, yellow, with reddish-brown markings. This variety was awarded a first-class certificate by the Royal Horticultural Society at London, August 28th last.

Francisque Morel.—Green foliage; and showy, vivid scarlet-crimson flowers. This variety received a similar award by the same Society, and at the same meeting, as did the last named.

Edouard André.—Crimson foliage; deep red flowers.

Gerard Audran.—Green foliage; flowers reddish or terra cotta color.

François Lapente.—Crimson-shaded foliage; dark purple stems, vivid red-crimson flowers.

Guillaume Coustou.—Green foliage, very strong; flowers yellow, spotted with red, fine.

Revol-Massot.—Green foliage; rich reddish-crimson flowers, streaked with yellow.

Princess de Lusignan.—Green foliage; reddish or terra cotta colored flowers.

General de Neigrier.—Crimson foliage; crimson-scarlet flowers.

B. Cousançat.—Green foliage; vigorous habit; orange-scarlet flowers.

G. C.

Chrysanthemums.

BEFORE the appearance of the chilly nights of late September it is well to have all *Chrysanthemum* plants under cover, as the cold nights, following the warm days, check the young growth and prepare the way for mildewed foliage and poor flowers. While it is a wise plan to keep the plants in the open air as long as possible, they should be securely housed in a light and airy structure before there is any possibility of frost, for, although the plants are quite hardy, the young buds are very tender, and often a slight frost, when they are just beginning to show, will ruin a whole crop of flowers. The house should be one that will admit an abundance of light and air, for good plants cannot be grown if either of these is wanting. When placed in the house the plants should have plenty of room—that is, they should not touch each other, but stand so that there may be a free circulation of air about them, and as soon as possible after they are under cover measures should be taken to prevent mildew, which otherwise may spread rapidly, to the great injury of the plants.

The most efficacious means of preventing mildew is fumigating the house with sulphur, but the grower should be warned that he is dealing with a very dangerous element if carelessly handled. Ordinary sulphur when evaporated is not injurious to the plants, but when heated above a certain degree it is converted into a very different thing—sulphurous acid—which is exceedingly destructive to living plants. Our method of applying the sulphur is by evaporating it over a small oil stove in a common two-quart agate-ware stewpan, filled about one-third or one-half full of flowers of sulphur. The wicks of the lamp are so arranged that the sulphur will boil without burning. As long as it does not catch fire it is safe, but the moment it does so the sulphurous acid is formed, and the house will be quickly filled with the choking, irritating gas, and the plants will appear as if they had been scorched by a severe frost. When simply boiled the sulphur is thrown off much like steam, and will crystallize in very minute particles upon every part of the plants, thoroughly eradicating every particle of mildew; and if this is repeated occasionally the plants can be kept entirely free from it.

As soon as the buds get large enough to be easily handled the plants should be disbudded, using a penknife with a small, sharp point. No set rule can be laid down for this operation, but generally speaking the plants set more buds than can be brought to perfection, and the superfluous ones should be removed if large and perfect blooms are wanted. Many varieties will form a full, strong bud at the extreme end of each shoot, with several smaller ones clustered close beneath it. These latter should always be removed in the large-flowered kinds, as they greatly interfere with the development of the bud that is to remain, and when a specimen bloom is wanted, not only these, but every other bud on the branch, should be taken away, so that all the energies of the branch can be devoted to developing the one left at its extremity. Soon after the plants are housed they need stimulating by some quick fertilizer to bring the blooms to perfection and keep the foliage green and fresh. Liquid manure made by leaching stable manure will answer all purposes, and should be applied rather weak, and quite often while the buds are forming. In fact, once a day, when the plants are badly pot-bound, will be none too often if it is applied in a weak state.

Ordinarily, artificial heat will not be needed in the house until the nights become cold enough to freeze or during cold, rainy weather, when a little heat will be found useful in drying the air.

Arthur H. Fewkes.

Gleichenias

GOOD examples of the various species of this lovely genus of Ferns are not so often seen as they should be, owing in part to the limited stock of some of the species, and consequent high price, and in part to the fact that some difficulty has been encountered by amateur cultivators in persuading them to make a strong and healthy growth. When given proper treatment they soon make exquisite specimens, and wear a more aristocratic air, so to speak, than almost any other class of Ferns, with the possible exception of some of the monarchs of the family, such as the Cibotiums, Alsophyllas and Dicksonias. As to what this best treatment should be, there is, perhaps, some difference of opinion, but I will venture to give in outline a treatment which has proved rea-

Gleichenias do not like to have their roots disturbed after the new growth begins. The propagation of this interesting genus is attended with some little difficulty, because most of the species do not produce spores in quantity, and, therefore, division of the rhizomes is the plan adopted to increase the stock, an operation that should be carefully done, so that each piece has as much root as possible attached, else it will be found hard to establish them. As to the best sorts to grow, it may be said that they all are beautiful, but the following are among the most free in habit and easiest to manage: *G. flabellata*, a strong-stemmed and large-fronded species from Australia; *G. dichotoma*, a charming companion plant for the above, its light green pinnae making a good contrast with the darker tints of its neighbor. Among the finer growing species *G. dicarpa* is, perhaps, the best, closely followed, however, in points of beauty, by *G. Spelunca*, both of the last named being natives of Tasmania, and all the sorts mentioned are best grown in a cool house, where they will make a much stronger growth, and are not so likely to become infested with insects.

A View in Central Park, Minneapolis.—See page 374.

sonably successful. The soil should be rather coarse and composed of good turfy loam and fibrous peat in about equal proportions, with about one-sixth of coarse sand. A little broken charcoal is a desirable addition to the soil, as it tends to keep it in a more wholesome condition. The Gleichenias being naturally shallow rooters, it is better to grow them in pans than in pots, and, in either case, to give them plenty of drainage, as their roots rarely go deeper than four or five inches below the surface. Good drainage is essential, for, though they like an abundance of water when in full growth, yet they are very impatient of any stagnant moisture at the root. A light syringing over the foliage should be given early in the day, and is beneficial during dry, hot weather, helping to keep the plant clear of thrips. In regard to temperature, the mistake is often made of keeping them (the Gleichenias) too warm, a night temperature of 45° to 50° being quite warm enough for most of the species during the winter season, and in summer they should be kept as cool as possible by shading and plenty of ventilation. The best time to give them a shift in pots is early in the spring, before the growth commences, as, in common with a majority of Ferns, the

This list may be extended considerably, but the species named are among the most satisfactory. W. H. Taplin.

Orchid Notes.—*Odontoglossum Razlii*.—This handsome Orchid is very similar in habit to the beautiful *O. vexillarium*, having longer lanceolate foliage of a much lighter green. It should be grown in a much warmer temperature than the last named species, the warmest end of the Cattleya house with abundant moisture suiting it to perfection. The plants, during growth, require every attention, as thrips often attack them, and when they once infest the Orchid it is difficult to dislodge them. Frequent syringings and dippings once a month in a weak solution of soot and tobacco water, will usually keep the plants free from this pest. When well grown this *Odontoglossum* will produce its flowers twice a year. These flowers are borne on erect scapes, three to five in number, during the months of March and April, and remain in perfection a long time.

Angraecum Leonii.—This is a native of the Comoro Islands, near Madagascar, and was introduced by M. Leon Humblot, who has already enriched our collections with many choice

and rare species. It was found at a very high elevation, where the atmosphere at all seasons was cool and moist. It is a free flowering species quite distinct in habit, differing entirely from others of the genus, having long, falcate leaves of a leathery texture, from the base of which stout, erect stems are produced, each bearing as many as twelve handsome blossoms of ivory whiteness, with tail-like spurs, measuring from six to nine inches in length. The flowers, which appear in February and March, are very fragrant, and, if removed to cooler quarters, will remain several weeks in beauty. These plants do not enjoy so much heat as the majority of *Angræcums*, but should occupy a light and airy position in the *Cattleya* house, and, if suspended in baskets or pans, will be found to thrive and flower freely in a mixture of clean, fresh sphagnum, and a small quantity of rough, fibrous peat.

A. D.

Kniphophia corallina.—This is a free-growing, free-blooming form of *K. Macoweni*. On March 6th of last year (1887), I sowed some seeds of it in a pot in the green-house, and in due time pricked them out into a flat, which I kept in a cold-frame all summer. Last October I transplanted them from the flat into a frame from which frost had been excluded in winter, and thence into rich ground out-of-doors last spring. They made very little growth last year, but they have grown vigorously this summer, and nineteen out of twenty-three are now, or have been, in bloom. As a rule seedling *Kniphophias* do not bloom till the third year from sowing-time. As nearly all the varieties are highly decorative plants, and especially useful for late blooming, we should treat them tenderly over winter. By mulching them deeply with dry leaves we can preserve them over winter in the open ground, but it is safer to lift them in fall and winter them in a cold pit, cool green-house or cellar. If an increase of some particular variety is desired at lifting time, we may shorten back the long leaves, then divide the crown into as many parts as we can separate with good roots to each, and plant these close together in a frame from which frost is excluded, in the same way as we do with *Ehemann's* *Canna*, and plant them out in the open garden in spring.

W. F.

China Asters are among the most useful of garden annuals. They are not only beautiful in form and color, but their lasting qualities add much to their value. The cut flowers do not easily wilt, and revive quickly in water when they do begin to droop. Early flowering China Asters mature much more quickly than the later varieties; but to prolong their lives take up a few of the choicest plants, place in small flower-pots, water well, and keep in the dark for a day, and you will soon have a living bouquet of rare beauty for in-door decoration, giving far less trouble than cut flowers, and remaining fresh and in bloom for weeks. The pots can, of course, be concealed if desired. A plant of Dwarf Bouquet taken up just in time to save it from the frost bloomed last year for five or six weeks, the opening buds often presenting curious variations of color and greater delicacy of tint.

The Forest.

Forestry in California.—II.

IN California a number of small tree-plantations have been made, and, I believe, with very satisfactory results. Several small groves of Locust trees have been reported as having proved profitable, the wood being sold for wagons, etc. The only figures I am able to give, however, apply to plantations of the *Eucalyptus globulus*. One case is that of Mr. Robt. C. E. Stearns, of Berkeley, who reports on a plantation of General Stratton, made in 1869; twenty acres were cut when eleven years old, every item of expense was noted, and a rental of \$5 per year was charged for the land. The net returns on the twenty acres were \$3,866.00. Another case is that of Mr. George A. Nadeau, of Los Angeles.

His figures are:

EXPENSE.	
Cost of trees at time of setting, per acre,	\$7.50
Labor of replanting, per acre,	5.00
Cultivation, per acre,	5.00
Rental of land for seven years at \$3 per acre,	21.00
Expense for seven years, total, per acre,	\$38.50
INCOME.	
Thirty-five cords of fire-wood per acre, at \$3 per cord in the tree,	105.00

Total expense for ninety-seven acres,	\$3,734.50
Total return,	10,185.00
Net profits,	6,450.50

California experience shows that tree-planting is profitable within reasonable periods, and gives returns as soon as some orchards, while requiring less care and less first cost.

From these points it will be clear that, looking at the forest in the most commonplace and most narrow practical view, scientific management is both advisable and necessary. Without it, this immense crop of the forests must disappear, to the great detriment of the country.

While these considerations would doubtless be deemed fully sufficient to a business man to warrant a change in our forest policy, looking to the preservation of the woods from waste and fire, and to the maintenance of their natural reproduction to replace the legitimate demand of trade, there are still other reasons of more pressing force which demand forest-preservation. These are the sanitary and climatic influence of forests, and still more their effect on the agricultural productiveness of the country through the precipitation and distribution of moisture controlled by them, and their importance in equalizing the flow of streams and in maintaining springs. The sanitary influence of forests is well understood by investigators. It will be well, however, to give a few illustrations on this point.

The Roman Campagna in ancient times was covered with woods and groves. From it sprang one of the hardiest and most forceful races of the world. We must therefore infer that it was a healthy locality. Since the clearing of this district, and through modern times, the Campagna has been one of the most deadly miasmatic regions of Europe. Within recent years considerable plantations of trees have been made upon its desolate wastes. One of the largest of these was made upon a large estate near Civita Vecchia. The trees were principally *Eucalyptus*. The amelioration in the health of the locality was prompt. Whereas laborers only remained on the estate in the day and departed to safe places at night, losing much time in traversing the long distance between their work and their shelter, after the growth of the trees they were able to remain with impunity in the district itself. Another plantation on the Campagna was made by the priests at the grand church of St. Paul. The benefit to the health of the fathers was in this case equally marked; the malarial fevers have become less frequent and less deadly.

The Island of Cyprus was formerly celebrated for its luxury and refinement; it contained a large population and was at that time, at least in its mountainous parts, covered with forests. It has been cleared and is now a desolate island of bare rocks, with a few cultivated valleys. It is subject to virulent forms of malarial disease, and contains not a hundredth part of its former population and none of its prosperity. Since the English occupation forest plantations have been commenced on a large scale, but it is too soon to know their effect.

The shores of the Mediterranean show numerous cases similar to these. The island of Mauritius is still another, but we do not have to leave our own country to prove this count. The records of the huntsmen and adventurers who first traveled the wooded western States of America make no mention of malaria as a dreaded malady. The record changed when the settlers came; these cut the trees, and it was then, and only then, that malaria became the scourge to humanity that it is in parts of the United States. While this evidence cannot be held as conclusive, still all experience seems to confirm it. The planting of belts of trees in malarial districts protects localities previously subject to malarial influence. It must be understood, also, in this connection, that the clearings in the western States were a necessity, malaria or no malaria.

Many diseases common in open countries are rare or absent in wooded ones, wherever considerable village populations exist, as in the Black Forest of Germany. The death-rate in the communities of the Black Forest is lower than that of any other part of Germany. Consumption is the disease which, amongst civilized nations, counts the greatest number of victims. In forests this dreadful malady is practically unknown. This fact is now so well recognized by medical men, that they send their patients, even in a climate like that of northern New York, to the Adirondack woods as a cure, to remain not only in summer, but in winter also. The beneficial effects of the Pine forests at Arcachon, in France, and in our southern States, have been availed of in phthisis.

Fog, it is now known by a number of well regulated experiments, is impossible without dust of some kind in the air. In this connection it may be well to call attention to the explanation of our California coast fog. In summer the upper

rents of air are from the coast to the sea. These are charged with dust, which gradually drops out of them, as they lose force on leaving the land. This dust falls into the sea atmosphere, which is charged with moisture, and fog is the result. Fog is irritating to those with weak or defective lungs. In forests this dust, with moisture surrounding it, is sifted out by the foliage, and fogs in forests are always modified, and if the exposure be favorable, are entirely eliminated. Fogs do not occur in dense forests.

Trees all have some odor and many a balsamic and agreeable one. Of such trees the Pines, Firs, Cedars, Eucalyptus and Laurels, Bay and Camphor trees are the best known. The emanations from these have, in general, a sedative effect upon the nervous system, but a stimulating one on the vital functions. These classes of trees are health-giving to the human being, and, to an equal degree, they are fatal to germ life. The importance of this effect will be recognized when we reflect that many diseases are caused and transmitted by germs. Insects will not congregate upon pitch, camphor, myrrh, etc., and the burning of these and many other tree products, as the leaves of Pine or Eucalyptus, stupefies and kills insects and germs. Some vegetable products, as pyrethrum, are more noted and deadly than others.

The philosophy of the attraction that pleasing odors have for man is well worthy of study. The taste or instinct for them is as useful as its complement, the dislike for bad smells, which enables us to avoid infected places.

In the tree the sap mounts from the roots in a crude state, composed of water (oxygen and hydrogen) and a slight admixture of earthy salts; it is carried to the leaf, when it is elaborated by the chlorophyl or minute grains that give the leaves their green color, when carbonic acid is absorbed from the air, and oxygen is liberated from the sap by the decomposition of the carbonic acid. Carbonic acid has a debilitating effect on man, this the tree absorbs; while oxygen is man's life, and this the tree gives.

Trees, while preservative of moisture in dry situations, have a great drying power when moisture is excessive, as in swamps and malarial lands. Few persons realize what an extraordinary amount of moisture a tree is capable of evaporating into the atmosphere. The evaporation takes place through the stomata of the leaves. Of these mouths, 90,000 have been counted on the lower side of the Cherry Laurel leaf, which is devoid of stomates on the upper side; on the leaf of the Lilac 160,000 have been counted. There is a great diversity in this respect amongst plants. The only experiment with which I am acquainted relating to the amount of evaporation which can take place through leaves of trees is that of Marshall Vaillant quoted by J. C. Brown. He took a branch of an Oak and placed it in a vase full of water. He measured the water lost through its leaves and considered himself enabled to conclude that the tree from which this branch had been detached would emit into the atmosphere in twenty-four hours upwards of 2,000 kilogrammes of water, equal to a little more than 5,000 pounds. The abnormal condition under which this experiment was made must cause it to be considered as only an indication of what may take place under normal conditions.

A flow of sap from wounds made in trees for commercial purposes is another indication of this power of taking up water. Pine trees tapped for resin, Camphor trees for camphor Gum and Rubber trees for rubber, show a great flow of sap, but I know of no measure having been taken of it. But measures have been taken of the flow of the Sugar Maple (*Acer saccharinum*) and the yellow Birch (*Betula excelsa*). Emerson cites a Maple six feet in diameter that yielded thirty-one and one-half gallons of sap in twenty-four hours, and Marsh cites one in Warner, New Hampshire, two and one-half feet in diameter, which yielded twenty gallons in eighteen hours; Dr. William cites a large Birch tapped in Vermont, the flow of which was measured from time to time for four or five weeks. The sap ran at the rate of five gallons per hour, progressively diminishing. The total yield was estimated at 1,890 gallons. The flow from these trees was only from one or two auger holes and was insufficient to immediately injure the tree.

When we consider the number of trees which thrive on a single acre we may perceive how important their collective action may become. Trees drain a soil in still another way. Their roots penetrate into the soil and make permeable strata that would otherwise be impervious to water. The channels made by the roots become a means by which surplus water finds its way into substrata, from which it appears later as springs in lower situations. The life activity of plants produces on the oxygen of the air a condition known as ozone. When in this condition oxygen is opposed to germ life, and,

consequently, to all forms of putrefaction. From these points it can be understood why a district is healthier in forests than when it is cleared. The more complete the clearing, the more complete the change. There are other beneficial influences of trees on health, some of which are discussed under another head, such, for instance, as their electrical influence, their equalizing tendency on winds and temperature, and their maintaining effect on springs, whereby wholesome water is secured.

Abbot Kinney.

Correspondence.

Ulmus effusa.

To the Editor of GARDEN AND FOREST:

Sir.—I do not know whether you remember a tree which particularly attracted your notice during your last visit to Berlin. Large, fine and old, it was, nevertheless, no real giant tree, but was attractive through the peculiar form of its head, which, as I was able to tell you, was characteristic of the species, and not merely of the individual. I refer to an Elm on the banks of Lake Tegel, opposite the island of Scharfenberg, which rose tall and lonely from the edge of the wood.

It seems best to retain for this kind of Elm the name of *Ulmus effusa*, which Wildenow gave it in the year 1787, and which appears as the oldest of published names, although that of *U. pedunculata* had been given it by Fougereux three years previously, and had been read at a meeting of the French Academy of Sciences, but never published. Other synonyms are *U. octandra* and *U. ciliata*. The species belongs particularly to the province of Brandenburg. At least I have never seen such enormous examples in any other part of Germany, or the neighboring countries, as grow on the banks of the Spree and the Havel. The trunk attains the size of an Oak and a far greater height. Specimens seventy or eighty feet in height are not uncommon, and there are some of at least 100 feet. In old age it forms sharp, protruding ribs at the base of the trunk, which have deep concave recesses between them. These natural buttresses evidently greatly increase its power of resisting storms and render effectual help in the struggle for existence. Higher up, the trunk becomes more cylindrical, although always inclined to be irregular, and shows an abundance of young shoots, especially where the tree stands on the edge of a wood. Branching generally begins only at a considerable height. But it is difficult to describe the head, which is a wonder of picturesque beauty, easily surpassing in this respect all other trees in Germany. It must be seen in winter to be fully appreciated, although even at other times it makes a marked impression. The branches bend and twist in the strangest curves, often even more fantastically than those of the Oak. Sometimes they shoot outwards, sometimes bend back, and let the playing light penetrate to the very depths of the head. The higher its crest, the more enchanting is its shape, the more it combines grace with power, the more the slender young shoots contrast with the robust forms of the branches. At last it is a whorl of thin, flexible ramifications that droop and hang somewhat like the branches of the Weeping Willow, although not so low. High up over all, however, tall leaders spring out, which add variety to the top. In short, the shape of the head is almost impossible to describe in words. It is quite different in effect from that of the much more familiar *U. campestris*. Its foliage is the least attractive part of *U. effusa*. It cannot be called beautiful, and if compared, for example, with the glossy foliage of the Linden, has a certain poverty of appearance. The rather large, one-sided and unevenly-toothed leaves are rough to both eye and touch, are not very closely placed, and form a surface of dull, dead green. But seen from a distance these defects do not prevent this Elm, wherever it stands, from being an ornament to the landscape. As with all other species of Elm, its blooming period is very early. Its fruit ripens in the month of May, and is produced in very great profusion, so that its first green in spring is due to the fruit and not to the leaves. The effect is extraordinary. Seen from a distance, the brown masses of hanging blossoms give the illusion of autumn coloring. Then follows the transparent green of the unripe fruit, and the leaves do not finally appear until the fruit begins to ripen and add its shading of brown. Although chickens and other poultry greedily devour the seeds of this Elm, its spontaneous distribution is considerable.

U. effusa belongs exclusively to Middle Europe, Germany forming the centre of its area. In Sweden it is not to be found, nor in Italy, except along the northernmost limits of Lombardy. In its wild state, in the province of Brandenburg, it likes the damp, deciduous woods and the swampy banks of

streams, and especially of lakes, so that Gleditsch appropriately called it the Water Elm. Almost all our village Elms belong to this species, and in such places it is more common than any other tree, and vies in size and beauty with the Linden. It is a pleasure to see these giant trunks, sometimes of enormous circumference, shading the village streets or standing in the farm-yards, and serving as supports for the farmer's tools. In these places the accumulation of animal matter is probably one of the causes of its fine development. Without its Elms a Brandenburg village would hardly be conceivable. They are far too plentiful, however, even the oldest among them, for us to fear any marked decrease in their numbers.

Elm bast was formerly used for tying plants, but has now been superseded by Russian Linden bast, and in many gardens by African Replica (?) bast. Yet it is still used in some villages around Berlin for tying beans to the poles, as it is considered more flexible than any other fibre.

Even Rossmueller, in his celebrated book on "The Forest," confesses never to have seen any variety of *U. effusa*. In this respect it forms a great contrast to *U. campestris*, which is so rich in varieties. A specimen raised and growing in Berlin, however, has parti-colored leaves. Seedlings have also been successfully raised to form pyramidal trees, which remind one of *U. Exoniensis*. Specimens of this sort are to be found in the new public cemetery of Berlin, near Friedrichsfelde.

In measuring the Elms of this species in the province of Brandenburg, I have found the maximum to be a circumference of six to seven metres and a diameter of about two metres. Such dimensions permit the conclusion that the age of these trees reaches back into dim antiquity.

As an avenue tree, for which it has been most successfully used for a long time in this country, it can be warmly recommended to our American friends, more especially as it thrives in very scant soil, provided it is not too dry or too compact.

Scharfenberg, Prussia.

(C. Bolle.)

[*Ulmus effusa* has been considered by some botanists a variety of *U. campestris*. Carl Koch, however, whose knowledge of European trees was perhaps unrivaled, agreed with our learned correspondent in believing it to be a distinct species ("Dendrologie," ii. 419). The oldest published name of this tree, antedating by three years that of Willdenow, appears to be *U. laevis*, of Pallas ("Flora Rossica," i. 75, t. 48, f. F.), published in 1784.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—The kind notice of the Onteora Club (the official title of which is "The Catskill Mountain Camp and Cottage Company") in a recent number of your paper tempts me to write you a few words with regard to the condition of the forests in our neighborhood.

The original growth upon this section of the country consisted of large Hemlock trees. These were robbed of their bark some eighty years ago by the tanners from whom Tannersville takes its name, and the ruins of whose long-abandoned and almost forgotten tanneries may still be seen on the banks of the streams in the various ravines of Greene and Ulster Counties. After the tanners had secured all the bark they could utilize, whatever of good lumber was left was secured by lumbermen, who rafted it, where possible, into the Mohawk and Hudson Rivers. The mountain streams have perceptibly diminished in size, undoubtedly owing to the reckless destruction of these large tracts of forest. So many years have passed since this destruction was effected, that a new growth now covers most of the slopes, and there is very little of that nakedness of aspect which so distresses the eye in many parts of the Adirondacks. Yet this new growth is itself in danger of destruction, for many of the mountains are being fast despoiled of their young timber by the chair and furniture factories which now abound in our vicinity. Our woods consist chiefly of Birches, Beeches and Maples, the original Hemlock forest having, in no case, started again in the second growth. The Beeches seem the most hardy and pertinacious, growing in some places in dense thickets so closely that it is impossible to force one's way through them.

It is our intention to look after the trees on our own land as carefully as we can, cutting out all the dead trees, trimming off dead limbs as close to the trunks as possible, and watching the undergrowth with a view to its future as part of the forest. We shall also use our best endeavors to influence local public opinion with regard to forest preservation; and I may note, as a matter of minor interest, that we have already planted

long stretches of roadside with shade trees, choosing the indigenous Maples for this purpose.

Dunham Wheeler,

Supt. "Catskill Mountain Camp and Cottage Co."

115 East Twenty-third Street, New York.

To the Editor of GARDEN AND FOREST :

Sir.—Burr Oak grows in the bottoms in this region, but I have never seen it cultivated. Its timber is valuable and we would like to plant it on tree claims, but do not know how to take care of it. Will you kindly inform us?

A. S.

Jamestown, D. T.

The Burr Oak grows in Dakota. I have examined it on the Red River, the James, and on the Missouri, in Dakota, but from observation and after diligent inquiry, I have learned that it is brittle and of little value compared with Burr Oak timber from further south, where this is quite a rapidly growing tree. In northern Dakota it grows very slowly, much too slowly, where I have noticed it, to make it a profitable tree to plant. Even the acorns of the Burr Oak, near Jamestown, are not as large as hazel nuts, while further south, where this tree is fully developed, the acorns are quite as large as hickory nuts.

Collect acorns as soon as they fall from the tree in autumn, and keep them in moist sand or earth during winter. Sow thickly in drills, and let the seedlings stand one, or not more than two, years, in the drills. Shorten the tap-roots before planting. Many writers claim that tap-rooted trees will never reach their greatest development unless the root is preserved. Experience teaches, however, that the root-pruned tree will soon make a larger and more symmetrical tree than the seedling which has not been transplanted. Examine the stumps of native Oaks ten years old, or those that are fully grown, where they have been extracted by a stump-pulling machine, and you will see that the trees which depended the shortest time on their tap-roots have the best balanced roots, and consequently grew into the best specimens. Robert Douglas.

Recent Publications.

The Tuberous Begonia; its history and cultivation. Illustrated. Edited by B. Wynne.

This is the first of a series of popular works upon subjects directly connected with gardening, which the proprietor of the *Gardening World*, a London periodical, announces. The improvement of the Tuberous Begonia is certainly one of the most interesting achievements of modern gardeners. It seems only yesterday since these plants were first made known, and yet the flowers of no other class of plants, perhaps, have ever been so essentially modified and so improved from the florist's point of view at least, in such a short space of time. It was not until 1864 that the first of these plants was discovered in Bolivia by Mr. Richard Pearce, a collector of the Veitches; and it was not until three years later, at the Paris Exposition, that this plant was exhibited and subsequently described as *Begonia Boliviana*. In 1865 Mr. Pearce discovered, in Bolivia, the yellow-flowered species which bears his name. Two years later this indefatigable and successful collector discovered, in the mountains of Peru, at an elevation of more than 12,000 feet, *Begonia Veitchii*. Unlike *B. Boliviana*, which has small, drooping, narrow-petaled flowers, the Peruvian plant had flowers much more nearly round in outline, and as the progenitor of the modern varieties with the much prized circular flower, its introduction was important. *Begonia roseiflora*, a native of the Andes of Peru, reached England in 1867. This species, although one of the parents of some of the early varieties, has never played a very important part in the improvement of these plants. *Begonia Davisii*, discovered by a Mr. Davis while collecting in Peru for the Veitches, did not flower in England until 1876, and did not appear in commerce until nine years ago. It is a dwarf species with bright scarlet, erect flowers, and smooth and glossy foliage, characters which, when it is crossed with strains derived from *B. Veitchii* or *B. Boliviana*, it has succeeded in transmitting to its offspring; and it is said that nearly all the newer single-flowered varieties, as well as the new race of dwarf, upright, double-flowering varieties, owe their best qualities to *B. Davisii*. *Begonia Clarkii* is only known from a plant discovered in an English green-house, but is believed to be originally from Peru. It is less hardy

than the other tuberous-rooted species, and has been little used by the hybridizer.

From these six species, none of which had been seen in European gardens until twenty-one years ago, the whole race of Tuberous Begonias, single and double, is descended. The fact is interesting as showing the influence of one commercial establishment upon modern horticulture, that five of these six species were discovered and introduced into cultivation by collectors of the house of James Veitch & Sons, which has done more than any one single agency in the last fifty years to increase the number of plants cultivated in gardens. The earliest hybrid Begonia was raised in their establishment by John Seden, whose skill as a hybridizer is commemorated in many genera, by crossing *B. Boliviensis* with an unnamed species, it is said. Other varieties soon appeared, and good strains were raised by English and continental growers, and it may be said by American growers also.

It is needless to attempt to describe all the varieties of these plants, or to mention the different crosses to which they owe their origin. This information, and much sound advice about the care and cultivation of these plants and the use to which they can be put, and other information concerning them, will be found in the little book whose title we have given above. Tuberous Begonias have many claims to popularity. The color of their flowers varies from the most intense scarlet to pure white, and to various shades of yellow. The plants are of neat and graceful habit. There is no plant, not even the scarlet Geranium, which, in flower, can produce a more gorgeous mass of color, or that can be used more effectively for certain decorative purposes. A blazing sun will not cause them to wilt, and the severest and most protracted rain-storm will not dim nor destroy the beauty of their flowers. A green-house is not needed to keep them over winter, as tubers enough to plant an acre or two may be stored in a moderate sized drawer. Tuberous Begonias, however, have their drawbacks. As cut flowers they do not last well, as the petals soon fall; they are practically useless for exhibition purposes, because they lose their flowers in traveling. Indeed, when the plants are grown in pots, it is almost impossible to move them about for conservatory or interior decoration. The Tuberous Begonia is essentially a plant which must be let alone, and allowed to remain where it has grown. The plants are now universally popular in England, and are seen everywhere in the great private show gardens and public nurseries;—where entire ranges of glass houses are devoted to their cultivation, in public parks and in the humblest cottage gardens. In this country, for some not very apparent reason, they are much less frequently grown, and yet the climate is better suited to them than that of England or of any part of northern Europe. The reason may be that we have not yet passed beyond the Scarlet Geranium stage, a disease which seems to have nearly run its course in Europe, or it may be that, as they are not good exhibition subjects, gardeners do not like them, and that, as they are not good for cut flowers, commercial florists cannot make use of them. The American public, at any rate, really know very little as yet of the possibilities in beauty and usefulness of Tuberous Begonias.

Periodical Literature.

In the August number of the *Pharmaceutische Rundschau* (a German periodical published in this city), Dr. Carl Mohr, of Mobile, prints the first of a series of articles on "The Distribution of Plants through the Agency of Animals," a most instructive and interesting chapter, dealing with plant-migrations in the eastern Gulf region of the United States, in so far as they have progressed without conscious action on the part of man.

The district Dr. Mohr's survey includes stretches from western continental Florida to the Mississippi and northward to the limits of the States of Mississippi and Alabama. Here, he says, more than 250 species of plants are known to be foreign intruders among those of native origin. Two-fifths of them have so accommodated themselves to local conditions that they may now be regarded as fully established in their new home. These belong in greater part to the flora of northern Asia and Europe, and in lesser part to that of the Mediterranean region or to the warmer zones of the eastern and western continents. Following in the footsteps of immigration, they remain for the most part confined to the vicinity of settlements, although some of them have spread abroad into the outer wilderness. Many of them are troublesome weeds which, coming from Europe, are now found over the whole of North America, to such a degree that it is sometimes difficult to decide whether they are naturalized or native. Foreign grasses are also found

in great variety, some of them having come without visible help from man, while others, like *Sorghum vulgare*, have been first planted and then spread abroad through the agency of birds. Among plants of tropical origin, *Richardsonia scabra* is noted as having spread, in the last forty years, over the whole sandy region near the Gulf, and as now extending into the highland districts of Alabama. This, the Pigeon Weed or Mexican Clover, makes excellent hay, and is a real acquisition to set against many serious nuisances.

Lospedeza striata, the Japan clover, a native of eastern Asia, offers a remarkable instance of rapid migration. First noticed near Charleston towards the end of the fifties, it was found at Macon in 1865, at Augusta in 1867 and at Montgomery in 1868, growing densely on the fields which had lain untilled during the war, and spreading into adjacent uncultivated regions. In 1869 it had reached Mobile County, in Alabama, having made the journey from near the Atlantic coast in a little more than four years. The war prepared the place for it; wandering cattle sowed its seeds in their excrement, and it now furnishes fodder of good quality in large quantities.

The Ailanthus tree of China is fully naturalized in the Gulf region, as is the Cherokee Rose, which, although some observers believe it to be a native, Dr. Mohr declares to be an immigrant from the same country.

Many plants, especially from tropical regions, have been introduced in ballast and cargoes to the neighborhood of coast towns. Some of them have wandered inland and become firmly established; others are still local or even sporadic. Birds and cattle have brought others from western America, some of real value; and birds, again, have brought others from the West Indies, while the track of industry is strewn with immigrants. In Prattville, Alabama, for instance, an interesting colony of Mexico-Texan plants has established itself in the vicinity of a wool factory, their seeds having been brought from the shores of the Rio Grande in the fleeces.

Helenium tenuifolium was first noticed by Dr. Mohr, growing in a street in Mobile, in 1878. Since then it has spread through Mississippi and Alabama northward for two hundred miles, crowding out the native plants and subduing the foreign weeds. Its home is in the Indian Territory and the western parts of Arkansas. It is a pernicious weed, spoiling fodder by its bitter taste; but the same district has sent to the Gulf States the Chicasaw Plum, which is now so thoroughly naturalized that it is often believed indigenous. Its distribution, like that of so many other plants, is attributed, even by the unlearned inhabitants, to the agency of birds.

Of course the interest of Professor Mohr's article is greatly decreased by the necessity we have been under of omitting the catalogues of plants which he gives in great numbers. We can do no more, however, than wish it may be translated entire for the benefit of those who do not read German. It is not only instructive and most interesting in itself, but, as he rightly believes, valuable as illustrating, with definite and varied facts, the manners in which vegetable transmigration has been carried on during countless ages in the past.

Exhibitions.

Window Gardening in Boston.

THE Window Gardening Exhibition at Horticultural Hall, September 15th, was most interesting and instructive as showing the progress of this admirable work. A marked improvement was shown in the condition of the plants as compared with those exhibited in 1887, and the large attendance of visitors and the number of contributors are most encouraging indications of even better results in the future.

Nearly 200 pots and more than 100 collections of cut flowers were on the tables. The display of W. E. Coburn, comprising forty varieties of wild flowers, and arranged with admirable taste, was a marked feature. The plants of nine exhibitors were deemed worthy of special mention as of superior excellence, and there were besides about seventy small gratuities presented to exhibitors.

A slight collation was served at twelve for those whose homes were distant, and was greatly enjoyed by about sixty children, mostly girls. The admirable deportment of the young people was noted by all, and was most gratifying to the Committee, who have given their services to this enterprise with the purpose of refining and elevating the tastes of the young, providing innocent and useful employment and making homes more cheerful and happy.

It may be set down as an educational fact that a child cannot daily care for a plant, study it and watch its development, and learn to love it, without a decided moral and spiritual improvement.

An attractive feature of the exhibition were two microscopic apparatus, contributed by the inventor, Mr. Stiles Frost. This instrument surpasses all others in the ease with which a flower can be observed, magnified and analyzed. It can be put into position and focused almost instantly, and is so simple that a child of ordinary intelligence can use it effectively. These instruments were surrounded by a throng of deeply interested little Bostonians, who could not withhold their cries of delight as they saw a flower, which before, to them, was only a mass of color, distinctly unfold under the glass its exquisite structure, texture and beauty, opening a new realm in the world of flowers.

During the summer there have been several local exhibits in other parts of the city, the most successful being at Orienta Hall, in Roxbury. Perhaps the most important work of the Committee has been in supplying plants to those that wish them.

These are furnished at cost, delivered free at some convenient distributing point. They are specially propagated, and great care is taken that every plant is of superior quality and certain to flower under proper care.

L. M. C.

Notes.

The second annual exhibition of the Society of Indiana Florists will be held at Indianapolis from the 13th to the 16th of November.

The joint meeting of the American Forestry Congress and of the Southern Forestry Congress will be held at Atlanta, Ga., on November 29th instead of November 12th, as formerly announced.

Harper's Weekly for September 22d contains a four-page illustrated supplement on "Irrigation in the Arid West." The paper was prepared by Richard J. Hinton, and it presents, in a clear and attractive way, the most interesting phases of the great material problem which must soon engage the attention of American legislators.

Some new seedling Gaillardias are mentioned as most promising among the plants in the early September exhibitions in London. The Gaillardia has already become a popular border flower since its great improvement during recent years; but these new varieties are very double and quite distinct from the single sorts. One of them, made up of tubular florets of bright red and gold, is spoken of as most showy.

The students of the Miller Manual Labor School of Albemarle County, Virginia, as a part of their botanical training, have prepared a collection of the native woods of their county, including more than eighty specimens, for the Richmond Exposition. The woods are prepared in blocks, in radial sections, with neat labels, giving the botanical and common name. The extent of the collection illustrates the richness of the forests of the foothills of the Blue Ridge in arborescent species.

Professor Budd, in the recently published report of the Ohio State Forestry Bureau, says, that his experience with the Honey Locust for fence lumber dates back some twenty-five years. Fence rails of that age nailed on posts have outlasted three sets of posts and two sets of Red Oak rails, and the Locust rails are yet mostly good. The rails were split and nailed on in June and July. Posts made from Locust timber, seasoned one summer before setting, and mixed with White Oak posts treated in the same way, lasted equally well.

Of the Viburnums, none are now more showy than the High-bush Cranberry, as its brilliant scarlet fruit lights up its heavy foliage. The neat Arrow-wood (*V. dentatum*) is also at its best now, with its large clusters of blue fruit and its shining leaves. The dwarf *V. cassinoides*, with pink and blue berries among its deep green leaves, makes a good companion for the others, and when planted on rich soil is hardly surpassed by any other shrub of its size. These Viburnums, beautiful during spring and summer in flower, foliage and habit, are doubly useful for the new charm they develop as their fruits ripen in autumn.

A correspondent of *Nature*, writing from Noumea, in New Caledonia, upon the dispersion of seeds and plants, records the fact that thousands of acres of pasture-land have been absolutely ruined on the island by the spread, through the agency of birds, of a species of Lantana, introduced by the first Catholic missionaries sent to the island, as a hedge-plant to surround their property at St. Louis, or Conception. The

history of the "*Gendame* plant" is not less interesting. It is an Asclepiad of which a seed was brought to the island from Tahiti by a *Gendame* in his pillow. The *Gendame* shook out his pillow, the seed, with its silky attachment, floated off, fell upon suitable soil, germinated, and now the "*Gendame* plant" has injured the island as much as the missionaries' hedge.

Mr. E. S. Carman, of the *Rural New Yorker*, early this spring undertook to raise Potatoes at the rate of 700 bushels per acre by planting them in trenches. These trenches were eight inches deep and one foot wide. The bottom of the trench was loosened with a prong hoe, and the cut tubers were laid one foot apart in the row. Then a thin layer of soil was placed over them and a dressing of sulphur added to discourage the cut worm. Mapes' potato fertilizer, 880 pounds per acre, was placed below the potatoes and the same amount above. Last week the crop, in five rows each thirty-three feet long and three feet apart, was harvested. The first row yielded at the rate of 684 bushels to the acre, the second at the rate of 605 bushels, the third at the rate of 1,076 bushels, the fourth 299 bushels, and the fifth 253 bushels, the entire plot yielding at the rate of 583 bushels per acre. The Cucumber flea beetle had injured all the tops, and especially those in the last two rows, which were of an early variety.

The managers of the Pennsylvania Railroad recently passed a resolution that all the bridges of short spans on the road should be rebuilt in brick or stone, instead of iron. They were actuated by purely practical considerations relating to the recent increase in the weight of locomotives which the improvements of the past few years have brought about, and the consequent inability of the iron bridges to bear the strains to which they are now subjected. But in commenting upon their resolve, *The American Architect and Building News* rightly says: "Aside from their greater safety, however, bridges of masonry have the æsthetic advantage of being usually interesting and often very beautiful objects, while iron truss bridges have never yet been endowed with anything more than an engineering attraction. The roughest stone arch across a roadway presents a beautiful combination of lines, a fine contrast of light and shadow, and a picturesque effect of landscape beyond, together with an expression of quiet durability which is more needed in our architecture than any other quality. . . . Already our country railway stations, under professional care, are fast becoming transformed from hideous sheds covered with clapboards into charming buildings of stone, picturesque, solid and convenient, often quite richly decorated, and generally surrounded by pretty and well-kept gardens. The better class of these new stations in this country are far more beautiful than those of foreign roads, and if the design of the bridges could be brought up to that of the roads, the line of every well-managed road would furnish a route of considerable architectural interest."

It is well known that a difference in luxuriance of growth shows, not only in the size and shape of plants, but also in their color, individuals which are well nourished being of a darker green than others of the same species which obtain insufficient food. But it is seldom that a knowledge of this fact is turned to good account in so curious a way as has recently been done by a German archaeologist, who has recently been excavating the remains of the Roman camp of Carnuntum, near Altenburg, a small town on the Danube between Vienna and Presburg. "It appears," says the *London Times*, "that Professor Hauser, ever on the alert, had for a month past observed the color of an extensive corn-field, which varied in every part. He found an elevated post of observation, and, after a week's close attention, declared it to be his opinion that the corn-field was growing over the site of an ancient amphitheatre. His drawings showed that the oblong centre piece was somewhat concave, and the corn was quite ripe in that part, because there was so much soil between the surface and the bottom of the theatre. Elliptical lines of green, growing paler the higher they rose, showed the seats, and lines forming a radius from the centre showed the walls supporting the elliptical rows of seats. The Professor waited impatiently for the corn to ripen, and the moment it was cut the excavations began. They have shown that the almost incredible suggestion was perfectly correct. Six inches below the soil the top of the outer wall was found, and from there the soil gradually grew thicker until the bottom of the arena was reached, the pavement of which is in perfect condition. From the theatre a paved road leads to the Camp of Carnuntum. As soon as the theatre has been entirely freed of soil covering it, all the measurements will be taken.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, OCTOBER 10, 1888.

TABLE OF CONTENTS.

Forestry Commissions.

THE preliminary reports relating to the forest-wealth of the United States, published by the Census Office six or seven years ago, gave rise to a very general discussion in the public press upon forests and their complex relations to the welfare and development of this country. The most visible outcome of this discussion, perhaps, was the appointment in a number of states of Forestry Commissions for the purpose "of preserving the forests;" and the question has been asked us more than once by members of these commissions how they can perform their duties so that the communities which created these commissions can derive the greatest benefit from these new organizations. In other words, what can Forestry Commissions in states like New Hampshire or Kentucky or Pennsylvania do to save the forests in those states? The answer is not an easy one to give. The states in which these commissions have been appointed own no forest-land whatever, with the exception of New York, where the state holds great bodies of wild and forest-land, and of California, where land has been presented to the Commission in order to enable it to carry out various experiments in silviculture.

So far as New York is concerned it is evident enough what the Commission ought to do. It controls or can control nearly 800,000 acres of forest-land; laws, still inadequate, certainly, although far in advance of those in any other state, enable them to protect this great property; and they are freely supplied with money for this purpose. It is within the power of the Commission, therefore, to put into practice some of the well known rules under which forests are protected and developed. If the Adirondack forest—or those portions of it, at least, which the state owns—is allowed to suffer, it will be the Commission and the Executive who appointed it who will be to blame.

In other states, where there are no state-forests to administer, and in which the Commissions are almost always left inadequately supplied with money, it is not easy to see how they can exert their influence directly. Administrative powers they cannot have, for no state-forests are

placed under their control; and the time has not yet come when private owners of forest-property will turn it over to be administered by state-officers. It is evident, therefore, that the field of usefulness for these commissions is limited, and that their work must be advisory and educational. They must become, if they are to justify their existence, the teachers of the people in all that relates to the forest. The Pennsylvania Commission, backed by an active society interested in forestry and equipped with a special organ devoted to disseminating information relating to the forest, has already made a beginning in this direction. But its efforts, as is natural in a new organization, lack system; and this is true of the educational work attempted up to the present time by the Commissions in other states.

As our advice has been asked, we shall be permitted, perhaps, to say that the Forest Commissions of the different States and their friends and all others interested in this country in the question of forest-preservation, will accomplish nothing until they unite together in the adoption of some general scheme for educating the people of the United States in the questions relating to the forest. What is needed in this country now is such a discussion of the forest-question, such an awakening of the intelligence of the American people to the importance of the forest, that it will be possible to secure (1) legislation from Congress, under which the forests upon the national domain may be administered for the good of the whole people of the United States for all time, and not for rings of contractors and timber thieves whose only interest is to cut every stick of timber, and then, after the forests are utterly ruined, abandon the land to hopeless worthlessness. Such an awakening is needed to secure (2) the enactment of laws in every state, under which forest property may be made secure from depredation and needless fires, and a condition of public intelligence which will make it possible, in the case of the forest, to subordinate private interest to the general good. But before this time comes the public of the country must learn that the welfare of the public is often dependent on the forest of the individual, and that if the individual is allowed to do with it all he may wish, he endangers the community. The time probably will come when the farmers of the United States will realize that the pasturage of animals in their woods is not only an injury to themselves, personally, but to the whole community, and will consent to forego this privilege; and they will learn that the clearing of the water-shed of a mountain stream or lake may bring incalculable injury to persons whose names they have never even heard. But the mental development which will make intelligent legislation upon such subjects possible can only come after long years of discussion and education. In inaugurating such discussion and in stimulating such education State Forestry Commissions will find their real and only field of usefulness, and failing in this they will show their unfitness for existence.

The Ailanthus.

A WRITER in a recent issue of the *Rural New Yorker* calls attention to the beauty and value of the much abused Ailanthus tree for planting in city streets. It is indeed one of the best trees that has ever been tried for this purpose, either in this country or in Europe, and no exotic tree, with the exception, perhaps, of the White Willow, has yet shown such capacity for adapting itself to the peculiarities of the American climate. The only possible objection to the Ailanthus is that the flowers of the male plants have an exceedingly disagreeable odor to some people, and that the pollen is supposed to produce catarrhal troubles. But, as the writer in the *Rural New Yorker* points out, this objection can be very readily obviated by raising plants from root-cuttings taken from the female plants only, and by avoiding the use of seedlings, among which there might be expected to be as many males as females. As the Ailanthus grows rapidly from cuttings, a supply of plants

can be secured quickly in this way. A moderately severe pruning of the male trees made in the spring every second year will generally have the effect of stimulating growth to such an extent that the trees will not flower.

Our contemporary hardly does justice, however, to the great economic value of this tree, which is surpassed, in the value of the material which it yields, by few North American trees; and certainly there is no tree which can be made to grow in the United States which can produce so much valuable wood in such a short time. The wood of the *Ailanthus* must be compared in heat producing properties with white oak, black walnut and birch. It is less valuable than hickory, but hickory—the best fuel, all things considered, our forests furnish—makes a no more agreeable, although a somewhat hotter fire, than *ailanthus*, which burns steadily and slowly without snapping, giving out a clear, bright flame and leaving a good bed of coals. The amount of ash left after the combustion of the wood is remarkably small. The great value of the *Ailanthus*, however, as a source of fuel supply, lies in the fact that it makes wood, even in poor soil, more than twice as rapidly as any of our trees which produce fuel of anything like the same value. The fact has not been demonstrated by experiment, but it is safe to say that an acre of ground planted with *Ailanthus* would yield at the end of thirty years more than twice as much fuel, in bulk and in actual heat product, as the same piece of ground planted with Hickory or Oak.

Ailanthus wood, in spite of the rapid growth which this tree makes, is both heavy and very strong. It neither shrinks nor warps in seasoning, and as material for the cabinet-maker it has few superiors among woods grown without the tropics. In color it is a clear, bright yellow, and although coarse grained, it can be made to take a fine polish.

Take it all in all, for hardiness and rapidity of growth, for the power to adapt itself to the dirt and smoke, the dust and drought of cities, for the ability to thrive in the poorest soil, for beauty and for usefulness, this tree, which the Abbé d'Incaville brought back with him from China more than a century ago, is one of the most useful which can be grown in this climate.

Notes from a Naturalist in Mexico.

FIRST impressions of a new country are often deceptive, and Mexico is such a large and physically varied region, that it would take months of travel to see even the most interesting parts of it; but having now passed through about 1,500 miles of the republic, the impressions made on one who has spent years in Eastern travel, but had never seen the New World, may not be without some interest. A tropical country without tropical heat or vegetation is, perhaps, what one would be inclined to say, and certainly the really tropical parts of Mexico, as regards natural productions, are very small as compared with the bare and treeless highlands. One might, however, say the same of India if one went from Peshawur to Bombay in the cold weather, and, as Wallace has so well pointed out, really tropical vegetation requires conditions which only exist in limited areas of the east coast and larger parts of the western slopes of the highlands of Mexico.

From El Paso, on the United States frontier of New Mexico, to the City of Mexico, one passes for sixty hours, at a slow railway speed, through interminable plains of an elevation varying from 4,000 to 8,000 feet, bounded by low, treeless and desolate-looking mountains, without seeing a single town of any real importance, a single glimpse of forest, or a green spot of earth excepting what is made so by irrigation; and the few small rivers crossed on the route are half or quite dry. The only striking plants seen from the railway are gigantic *Yuccas* and a few species of *Opuntia*, *Cereus* and other *Cactaceae* plants; but even these are not half so numerous or varied as one supposes from the great numbers which exist in the northern part of Mexico. When at last one arrives at the so-called Valley of Mexico—which is not a valley in the usual sense of the word, but rather a high-lying plateau, containing large lakes which receive the drainage of the hills around, and have no natural outlet—one expects to see a view of unparalleled grandeur, but this is, like many other popular im-

pressions, by no means the case. The distant cone of Popocatepetl and the more picturesque mountain of Ixtaccihuatl, which, though somewhat lower, has more snow at present on it, are no doubt very high and remarkable mountains; but their distance, the haze through which they are seen and the want of beautiful foreground in the view, make the scene, in my opinion, infinitely inferior in grandeur and in impressiveness to many of far less reputation, both in the Alps, the Pyrenees and the Himalayas. As to the climate, one must not be too critical at this season, especially when one has just left a winter of unusual severity, both in the United States and Europe, but it is not my idea of a tropical or even a very nice climate. Bright sun and continual almost cloudless sky, cool air, even cold in the morning, with glare and dust, are the characteristics on the plateau and highlands of Mexico for five or six months of the year. Pine forests, which I had always expected to find one of the features of the country, are diminishing yearly through the unchecked devastations of fire, charcoal-burners, goats and sheep, and I have not yet seen a tract of forest which has not been much injured in this way, or of which the more accessible parts have not been, in a great measure, destroyed. To find this one must go up to 8,000 or 9,000 feet on the slopes in the environs of the City of Mexico, so tempting to a naturalist at this season. We lost no time in going on to Orizaba, about two-thirds of the way in distance to the east coast, and at little more than half the elevation of Mexico City. Here, in the midst of Coffee plantations, Sugar Cane and Bananas, with the volcanic peak of Orizaba 17,000 feet high at a short distance, one can find, by looking for it, some really charming bits of forest, but always in deep gorges or barrancas, and never in easily accessible situations. Birds, as in the Valley of Mexico, are numerous and varied, but not especially striking in color, size or form. Butterflies are fairly numerous, but mostly belong to the family of *Hesperidæ*, which alone are common at this season. Moths, excepting a few day-flying *Ægeriadæ*, are scarce, and other insects, excepting Dragon-flies, not very showy or numerous. Orchids are fairly abundant, but few showy ones are now in flower, and though the gardens and plantations round the town are full of beautiful, showy plants in flower, of a more or less tropical character, such as *Hibiscus*, *Erythrina* and *Datura*, yet most of them are exotics. A fortnight's stay in Orizaba enabled me to explore the environs pretty thoroughly without finding a single spot within five or six miles which could be called a first-class collecting ground, though, at the same time, I feel sure that Orizaba would yield a very large number of plants, birds and insects to a resident collector. Tuxpango, about three hours to the south-east, is the best place I found, and here are some very picturesque waterfalls and a lovely tropical gorge, with some fine Coffee plantations under the shade of the forest, which pleased us more than any spot yet visited. On the mountains around Orizaba, which, however, are very steep and pathless, there are some rich and interesting spots in which I found a few fine plants and rare insects; but the sky, though generally bright in the morning hours, usually clouded by noon, and the weather was not nearly so hot as one would expect in latitude 19°, at 4,000 feet elevation.

Going on from Orizaba towards Vera Cruz, one passes through a very rich and fertile country, where Bananas, Pineapples, Coffee and Sugar are largely grown about Cordoba, and here in the plantation of M. Tonel, a Belgian gentleman, who has been settled in Mexico for many years, I saw a large number of species of Palms, and very many interesting and beautiful tropical and sub-tropical plants. Indeed, I should say this was by far the most interesting garden in Mexico, as the proprietor has a Belgian gardener, and goes to much trouble and expense in making his plantation rather a botanic garden than an ordinary Coffee plantation. But still there is no virgin forest until one gets on towards Attoyac, where the railway passes through some scenery of the true tropical character, and in the few hours I was able to spend here I saw what I had been hoping for so long. As, however, Attoyac is said to be very unhealthy at all seasons, and there is no accommodation for a stay, I could only regret my inability to give it a thorough exploration, though probably there is no great amount of novelty to be expected, this part of Mexico having been better worked by naturalists than any other. Below Attoyac you get into the dry plains bordering the coast, which are, for the most part, covered with low, thorny or scrubby forest or coarse, wiry grass, and infested with small insects called *pinolillos*, which, judging from the amount of precaution and trouble the inhabitants take to get rid of them, must be very disagreeable indeed. A gentleman who got into the tram-car on our way up to Jalapa, two stations out of Vera Cruz, had got amongst

these *pinillos* in passing through some bush, and spent over half an hour, with the assistance of several other passengers, in picking them out of his clothes. A magnificent yellow-flowered tree, figured in Brologsa's "Centrale America," was the most conspicuous ornament, at this season, of these dry, low-country jungles, for I can hardly call them forests, and here alone have I as yet seen Palms growing as a conspicuous feature in the scenery, though several dwarf and slender climbing Palms were common in the gorges about Orizaba and Attoyac, together with two fine plants belonging or allied to the *Musaceæ*, both in flower at this season.

Vera Cruz, though unusually cool and healthy for the time of year, owing to the heavy northerly gales which have prevailed during most of the month of March, and which account for the cloudy, cold weather at Cordoba and Orizaba, is not a place that would tempt any one traveling for pleasure to stay in; and as its hotels are detestable, we lost no time in getting off to Jalapa, which lies on the eastern slope of the mountains about fifty miles north of Orizaba. The old road up to Jalapa is said to give an excellent idea of the gradual change of climate and vegetation from the coast upwards; but if this is true, I cannot say the same of the new tramway, which takes one over the forty miles and 5,000 feet of ascent in about eleven hours, mules being the motive power, as on many other lines in Mexico. The first half of the way is all through the dry coast jungle or chapparal, as it is here called, full of Mimosas and other thorny trees and bushes. *Bromeliaceæ* are very conspicuous and abundant, as in most parts of this region, and several very fine arborescent Bonaparteas and gigantic *Cereus* were common at about 2,000 feet. But on the whole line there is not a single mile of forest which can be called fine or luxuriant, and water is so scarce that the villages on the route are both few and poor. One fair-sized river is crossed at Puente Nacional, and here we saw some lovely flowering trees, though the speed of the mules, except on steep ascents, did not allow much botanizing. A very graceful, feathery Bamboo, growing about fifteen feet high, appeared at about 3,000 feet in one place only on the road, growing gregariously among shrubs and trees, but beyond this I saw nothing very striking. When we got up to about 4,000 feet, an open, grassy country, with occasional trees, and small groves in the ravines, was entered, which, through the influence of a small, driving rain and dense mist, made the country look more like the Highlands of Scotland than Mexico; but, notwithstanding the cold, hedges of wild Pineapples showed that the mean temperature must be high. Jalapa itself, when reached, is decidedly the most enjoyable place of residence for a naturalist that I have yet seen in America. The climate is damper and cooler than that of any place of similar elevation I have seen. There are numerous bits of very charming country of varied character within a walk of the town. A very tolerable hotel, curé, and law-abiding inhabitants, a capital naturalist's servant, named Alyssio Trujillo, who accompanied us for some time, and can both shoot and skin birds well, and fine weather, all combined to render our stay at Jalapa a bright and delightful sojourn. There is between Jalapa and Coatepec a good deal of real virgin forest, abounding in plants, birds and insects, and having at least two broad and good roads through it, without which collecting in a virgin forest is so difficult and incomplete. At this season the forest, which consisted largely of Planes, Oaks, Liquidambers, and other trees of a temperate aspect, was dry and pleasant to go about in, and numerous small clearings in it made a variety which, if not carried to the extent which it generally is, is favorable to all animal life. On the north side of the town, at about an hour's distance, is a delightful park-like grazing country, covered with groves of trees, and intersected by richly-wooded gorges, a very paradise for birds, and having in fine weather a perfect climate, though it is said that the rainy days in the year outnumber the fine ones. Farther on towards the north we did not go, but Mr. Godman, who spent a month in and about Misantla, three days' ride north of Jalapa, describes the deep descent from the tableland to the dense forest as very fine, and the country extremely rich and productive to a naturalist. North-west of Jalapa is the Cofre de Perote, a volcanic mountain 13,000 or 14,000 feet high, with fine Pine forests on its slopes, but at this season the high country was too cold to visit for collecting purposes, and I am unable to say whether the Pine forests on this slope are as much damper and richer in herbaceous plants and accompanying insects than those of the central plateau, as one would expect them to be. We returned from Jalapa to Cordoba on horseback, a ride which, for varied vegetation, beautiful scenery, and general interest would be hard to beat in Mexico; and though on two of the five nights spent on the road our lodg-

ings were of a very primitive character, yet a lady was able to enjoy it thoroughly. Some of the barrancas—five crossed on this ride—are very deep and perpendicular; two rivers have to be passed on rafts, the horses swimming or wading, but the ride along the edge of the Barranca de los Pescados, ascending from 2,000 to about 5,000 feet, on the second day, has many very fine views indeed, and the peak of Orizaba, both on this and the next day, is an object of culminating importance. In the Oak forest between Las Balsas and Pinea *Bromeliaceæ*, Orchids and other Epiphytes were in the greatest abundance. I gathered thirteen or fourteen species of Orchids in an hour from the low trees without getting off my horse. This was between 3,000 and 4,000 feet, but a few miles further on we got into a region where, though the forest was much finer and denser with green undergrowth, Orchids were not so numerous or varied.

We saw a fine dark crimson Hibiscus, with a trailing habit, in this part of Mexico only, and a splendid Gesneriaceous plant of great size growing in the damp, shady ravines, together with many Tree-Ferns and other large and handsome Ferns, which seemed more abundant about San Bartolo than anywhere I have yet been. In fact, we thought San Bartolo as good a place for collecting as any in this part of the country. It is charmingly situated in the midst of a good deal of virgin forest, at about 5,000 feet, and within easy reach of deep, hot gorges full of purely tropical vegetation, and close under the high slopes of the Volcano of Orizaba.

Beyond Huatusco, where we slept on the third night from Jalapa and found very fair quarters, the country becomes less broken and picturesque, though still very pretty. Returning to the high plateau of Mexico, we found the contrast between the dry, dusty, windy climate and the region we had just left, even more striking than at first. Round Pueblo, where we stayed a week, there is little or no indigenous vegetation, except here and there on dry rocky hills and in the few places where the soil is too poor for cultivation. The Malinche, an extinct volcano of 13,000 feet, is covered on its lower slopes with stunted Pines, which are fast succumbing to the attacks of the woodman and charcoal burner; but the only spot where we have found any forest at all likely to contain much of interest is at El Pinal, about twenty-five miles out on the railway leading to Los Llanos, and here are a good many birds and insects quite different from those yet seen, and some *Vacciniæ* and other plants, which are apparently quite at home on the dry sandy granite, of which these hills seem to be mostly composed.

Cirencester, England.

Foreign Correspondence.

London Letter.

A GOOD number of first-class certificates were awarded to new and rare plants and flowers at the meeting of the Royal Horticultural Society to-day, the most important of which was the Nepaul Lily (*Lilium Nepalense*), which has flowered here for the first time in cultivation. It was introduced and shown by Messrs. Hugh Low & Co., of Clapton. It is distinct and beautiful, and its certificate-vote was unanimous. The only Lily with which I can compare it is the rare *L. polyphyllum*, also a native of the Himalayas, which is somewhat similar in growth and flower. The stem of *L. Nepalense* is slender, about three feet high, sparsely furnished with short and rather broad, deep green leaves. Each stem is terminated by a single flower, which is about four inches across, and with sepals and petals reflexed. The ground color, an intensely deep purple-crimson, is mottled with yellowish-white, and the tips of each petal are of the same pale color. It cannot be termed a showy Lily, but it has a peculiar form and color which every one admires. Mr. Baker, the authority at Kew on Lilies, had never before seen it in flower, though he knew it well by descriptions and illustrations. It is a native of the temperate portions of the western and central Himalayan region, and it may not prove a perfectly hardy plant in England. If, however, it is not hardy, it is a beautiful green-house Lily.

The certificated plant next in importance was the exquisite white-flowered variety of *Oncidium ornithorhynchum*, an Orchid as rare as it is beautiful. It is the counterpart of the typical form now common, except that the

flowers instead of being pink are of ivory whiteness with golden-yellow crests. They possess the same delightful perfume which some compare with the scent of newly-mown hay. The flowers are small, but very numerous, and are borne on a loose spike which drops in a graceful way. The exhibitor of this treasure was Mr. B. S. Williams, of Holloway nurseries.

The lovely *Romneya Coulteri*, of California, introduced over a dozen years ago, was exhibited for the first time in flower to-day, though it has flowered several times in various gardens of late years. Mr. T. S. Ware showed it on this occasion, and its beauty so won the committee that its certificate-vote was unanimous. [This plant was described in the issue of this Journal for August 15th.—E.D.]

A variety of the well-known Cape bulb, *Tritonia aurea*, with crimson blotches on the orange-red sepals, was shown by Mr. James O'Brien, and received a certificate. It differs from the typical form chiefly in the color of the flower. The crimson blotches are conspicuous, and increase its beauty. This *Tritonia* is one of the showiest of bulbs for the green-house during August and September, and in some of our southern gardens it is perfectly hardy.

Eremurus Olga, a noble Liliaceous plant introduced a few years ago from Turkestan, was shown by Mr. T. S. Ware, and received a certificate as a first-rate hardy herbaceous plant. All the *Eremurus* have long narrow leaves like an *Asphodel* or *Kniphofia*, and produce tall spikes crowded with small blossoms. *E. Olga* has a flower-stem rising from three to five feet in height, and for fully half its height is furnished with small white flowers. The flowers expand from below upwards, and as from six to nine inches of the stem carry expanded flowers at a time, it is some weeks before the spike is exhausted. It is quite hardy here.

The Chrysanthemum season has already commenced, the first new variety being shown to-day; it was so fine that no hesitation was made in certificating it, notwithstanding the many fine early varieties we have. This sort is called Mrs. Hawkins, and is a sport from another fine variety called Wormig's Yellow. The flowers of Mrs. Hawkins are from five to six inches across, very full but flat, the florets being long and narrow. The color is a rich golden yellow. The vigorous growth, fine habit and floriferousness of the novelty had a good deal of weight with the committee. From this date onward to February and March we have Chrysanthemums at every meeting, so that we might well say that their season extends through half the year.

A very fine new white Carnation named Madame Carle was certificated on account of its free growth, abundant bloom, fine form and the purity of its strongly perfumed flowers. It is a first-rate market variety, as it flowers almost constantly. The exhibitor was Mr. May, one of the chief growers for market, who also showed finely flowered specimens of such favorite sorts as Miss Joliffe, pink; Dr. Raymond, crimson-clove; Pride of Penhurst, yellow; and Andalusia, which last is considered the finest yellow of all for market, as it is hardly ever out of flower. The color is not so pure as that of Pride of Penhurst; but the flower is finer and fuller, while the growth and habit is vastly superior.

A new hybrid *Dianthus* named Splendor was certificated as a first-rate border plant on account of its dwarf, compact growth, profusion of bloom and rich color. It is a cross between *D. Heddewigii* (generally treated as an annual) and the Sweet William (*D. barbatus*). The progeny is quite intermediate both in growth and flowers, which are about one inch across, with fringed petals and borne in loose clusters. The color is an intensely deep crimson with mottlings of black on the petals. The exhibitor of it, Mr. R. Dean, also showed a double white variety of *D. Heddewigii* called Snowdrift, with flowers of remarkable purity.

Among the crowds of new Dahlias put before the com-

mittee, including double, single and cactus varieties, there was but one considered worthy of a certificate. This was a single Dahlia named Mikado, a large well-shaped flower of a bright Indian red streaked and tipped with yellow. It won a certificate by a narrow majority, as some of the committee, myself included, considered it by no means beautiful. In Kelway's collection of Gladioli there were numerous new seedling sorts set up for certificates, but only two were selected. These were Castro and Besler, the first having enormous flowers of a delicate carmine-pink tint with white centre and lower petal, while the second was a smaller flower and spike, vivid crimson-red flaked with a deeper tint. The hundred or more spikes shown to-day were, if anything, finer than those shown a fortnight ago, the splendor of which I alluded to in my last letter.

Besides the first class certificates awarded, there were two Orchids that received botanical certificates, which mean that although the plants are interesting botanically or are rare, they do not, in the opinion of the floral committee, possess sufficient merit for general cultivation. These Orchids were *Disa graminifolia* and *Lælia (Trigonidium) monophylla*, both of which, in my estimation, possess exquisite beauty, though small in growth and flower. The *Disa* is a South African species, having tiny tubers that send up very slender flower-stems before the grass-like foliage. The flowers are less than an inch across, but are of a lovely purple-blue color, which is so rare among Orchids. The *Lælia* is a pretty plant, too, of tiny growth, somewhat like a *Sophronitis*. Its flowers are about one and a half inches across, and of a bright orange-scarlet. Though so small, this Orchid is one of those for which extravagant prices have been paid, perhaps more on account of its rarity than its beauty.

Lilies formed a conspicuous feature in the show, and of *L. auratum* alone there were probably a hundred spikes, representing numerous varieties. Our king of Lily-growers (Mr. G. F. Wilson) brought some wonderful specimens of *L. auratum rubro vittatum*, the variety with enormous flowers with each white petal broadly banded with blood red. He also had huge stems of *L. auratum*, var. *platyphyllum*, with flowers nearly a foot across, while from other gardens came the *Virginale* variety, whose flowers are devoid of the spots and blotches seen on the petals of the ordinary kind. The various forms of the Tiger Lily, *L. tigrinum*, were also in their full glory on this occasion.

London, September 11th, 1888.

W. Goldring.

New or Little Known Plants.

Tigridia Pringlei.*

THE Tiger-flower, the well known *Tigridis Pavonia*, a native of the valleys of southern Mexico, early attracted the attention of the Spanish conquerors, and became known by reputation under the name of *Tigridis flos* long before it had been seen by any botanist. It was first described by L'Obel (Lobelius) in his *Plantarum Historia*, published at Antwerp in 1576, where he gives a very rough but recognizable wood-cut of the plant from a colored figure which he had received from his friend, Joannes de Brancion. Hernandez also describes it in the *Historia Plantarum Novæ Hispaniæ* (1651), giving the same Latin name, *Flos tigridis*, and the Aztec name, *Oceloxochill*. He speaks of it as growing in gardens and cultivated fields about the City of Mexico, as though it were cultivated both for its flowers and for its edible bulbs. These descriptions, however, were so incomplete, that Linnæus was unable from them to place the plant systematically, and he made no mention of it in any of his works. In the

*T. PRINGLEI, Watson, n. sp. Bulbs small, with fusiform roots; stem slender, one or two feet high, bearing two or three winged-plicate leaves and a single flower; spathe-bracts three inches long, inclosing the peduncle; perianth with a campanulate base, blotched within with crimson, the sepals two and a half inches long, with a reflexed scarlet limb; petals broadly cordate or reniform at base, the narrower triangular-ovate, acute limb not spotted; staminal column one and a half inches long, the stamens five to seven lines long and equaling the style branches, which are cleft to the middle; capsule narrow, very obtusely angled, two or three inches long by three lines wide.

later years of his life he received many contributions from Dr. José Celestino Mutis, of Santa Fé de Bogota, especially of figures illustrating the flora of that region, and among them was included this species, which Mutis appears to have received from Mexico and to have cultivated in the botanic garden founded by him at Santa Fé. Upon the

the description by L'Obel, and on account of its brilliant, though fugitive, flowers, it has maintained its place in gardens ever since.

This species is the only one hitherto known belonging to the true *Tigridia* section of the genus, having large flowers and decurrent stigmas. Several forms are now to be found in cultivation, varying scarcely at all in the form and relative size of the parts of the flower, nor, I think, in the general character of the markings, but very greatly in the coloring. The section *Bealonia*, with much smaller flowers, and capitate or less distinctly decurrent stigmas, includes half a dozen species, natives of tropical Mexico, with one in Peru and Chili, and none of them common in cultivation.

T. Pringlei, which is the subject of Mr. Faxon's drawing for this number of GARDEN AND FOREST, is a recent discovery made by Mr. C. G. Pringle in the mountains of Chihuahua, much farther to the north than any other species has ever been found. As the figure shows, it is very closely related to *T. Pavonia*, and if color alone were to decide, it might be considered a variety of it, though differing markedly even in that respect from the old species. The base of the sepals is blotched (rather than spotted) with crimson, with a border of orange, the reflexed blade being of a bright scarlet-red. The petals have the base blotched and coarsely spotted with crimson, with a well defined, deeper-colored, brownish margin, the blade orange, tinged with scarlet, but not at all spotted as in *T. Pavonia*. The more essential difference is in the form of the petals, which have a broadly cordate or reniform base, with a much narrower, small, triangular-ovate, acute blade. The sepals also are smaller and more oblong in outline. In cultivation at Cambridge this season the bulbs commenced to bloom in July and continued to flower for several weeks.

Cultural Department.

The Vegetable Garden.

SPINACH, Cauliflower, Brussels Sprouts, Celery, Lettuces and root crops will now form the bulk of our seasonable vegetables from out-of-doors, but where precautions against frost have been taken, we may still have Snap Beans, Tomatoes and Cucumbers. There has been frost in this neighborhood, but on account of our proximity to the sea, there was none here. Our vegetable supply is still unbroken. Evergreen and Squantum Corn sown June 26th are still yielding good ears; Cory and Early Marblehead sown July 19th and July 23d are just about fit for use. These last two kinds were planted for use in case the larger varieties did not continue tender till the end of the season, but so long as any of the first three can be had in fair condition, the extra early sorts are not wanted. On the 23d of July I sowed some Golden Tom Thumb Pop Corn, and the ears are now (October 1st) not only full, but the kernels are hard and the crop almost fit to gather. It matures more rapidly than any other that I have tried.

Snap Beans are still excellent. Mohawks sown August 9th are now in use, and Valentines sown the same time will be ready in a few days. Calico sheets are spread over these when frost is threatened. Snap Beans were sowed on August 13th, to be covered with frames and sashes about the end of September or just before frost. These sowings consisted of Earliest Red Valentine, Thorburn's Extra Early and Early Etampes. Both the Valentine and Thorburn's are now in bloom and podding nicely, but neither of them is yet fit for use; the Early Etampes, however, are not only in bloom, but a large number of pods are in excellent condition for the table. By banking around the frames with earth or manure and covering them over at night with mats or thatch, this Bean crop can be preserved in good condition well through October.

The Turnips now in use were sown August 10th; they are Purple Top, White Globe and Strap Leaf, and are about two inches in diameter, tender and solid. Old or overgrown Turnips are very poor vegetables. As Turnips will have good growing weather till November, many of these sown August 10th will be too big for keeping over winter, but others, sown a fortnight later, will be better for winter use. The Turnip

Fig. 61.—*Tigridia Pringlei*.—See page 388.

data thus furnished, the younger Linnæus referred it to the south African genus, *Ferraria*, and published it in 1781 as *F. Pavonia*. The genus *Tigridia* was founded upon it by Jussieu in 1789. It was soon after introduced into England, where it first bloomed in 1796, just 220 years after

Beets, namely Egyptian and Eclipse, now in use, were sown July 18th, and the same sorts, sown July 27th, are also fit for use. But Long Blood Beets sown July 27th are not yet fit for pulling; they need a longer season of growth.

Water and Musk Melons, Cucumbers and Squashes are now past bearing and should be cleared off the ground. As soon as Corn, Tomatoes and Snap Beans have been bitten by frost, they, too, should be cleared off the ground. Limas are very tender. Where they have been grown thickly together it often happens that while the tops get frozen, many fresh leaves and young Beans along the stems escape unhurt; in such cases it may be well to let them alone till they are cut down by a more severe frost.

Celery has grown finely this season; the recent cold weather has suited it exactly, but, until the last week of September, we could hardly get dry weather enough to permit the earthing up of the crop, and to bank it up while it is wet causes it to rust and rot.

Frame crops now demand attention. It is useless to sow Radishes out-of-doors or in cold frames after this time of year. We must raise them in hot-beds or in a green-house. Wood's Early Frame, French Breakfast and Early Red Turnip are capital sorts. Snap Beans, Tomatoes and Cucumbers here have been covered with frames and sashes, and in the event of cold nights, mats or thatch will be spread over the glass. Some earth or manure has been banked up against the frames to help keep them warm. A few weeks hence these frames and sashes will be at liberty for use in covering Spinach and Cauliflower. Fill up all spare frames with Lettuces, keeping the large plants in frames by themselves and the small ones by themselves. But be careful at this time of year not to keep frame crops close and warm, else they will perish during severe weather in winter. A temperature which just escapes frost is the best for large Lettuces, and a few degrees of frost will do no harm to small Lettuces, Parsley or Cabbage plants.

Glen Cove, N. Y.

Wm. Falconer.

The Flower Garden.

IT often happens that after our first frost some bright, warm weather comes, and Dahlias bloom out again quite generously. But after tender plants are sharply nipped their partially recuperated beauty seldom compensates for their ungainly appearance, and it is often better to clear them away at once. Bulbous and tuberous rooted plants should be cut over close to the ground, and brought indoors and stored away for the winter, each kind according to its nature. The ordinary Cannas when lifted may be shaken free from earth and stored, one deep, on a shelf or floor in a dry, frost-proof cellar or shed, or under a green-house bench, but the finer kinds, as Ehemanni, should be placed on a moist earthen floor or planted in earth in a green-house or warm frame—anywhere where they may be kept growing. Dahlias may be treated as common Cannas. Montbrietias may be lifted and kept dry over winter after the fashion of other bulbs, but it is better to keep the roots in moist earth, either in pots or boxes, or planted out in benches or frames. Green-leaved Caladiums live well enough when wintered in the same way as Dahlias, only it is unsafe to keep them in a temperature lower than 45°. Tuberoses should be kept dry and warm; but Mr. Michels, of St. Louis, has found that the new Albino Tuberoses must be kept growing in winter in the same way as Ehemann's Canna. Last winter he lost three-fourths of those he dried off in the usual way. Tigridias should be tied in bunches and hung in a shed for some days, sometimes weeks, and then the bulbs, with stems stripped off, should be stored on shelves; but in all cases preserve them from frost, also from rats, which are very fond of them. Rats are also very fond of the tubers of the fancy-leaved Caladiums. Young bulbs of *Galtonia (Hyacinthus) candicans* are hardy enough, but old bulbs rot in the ground in winter. But as lifting and saving them indoors over winter are very little trouble, it is the safer plan to practice. Gladioli should be treated like Tigridias; but all the bulblets about the base of the large bulbs should be saved. These bulblets, sown next spring in drills about twelve or fifteen inches apart, and as thick as dwarf Peas, will, most of them, bloom when two years old. *Bessera elegans* may be relieved at once of its leaves and stem and the bulbs wintered in paper bags or on shelves. *Milla biflora* may be treated in the same way, except that it does not keep as well in a dry state as in slightly moist earth. Of these last two bulbs and of *Cyclobothra flava* there is likely to be a scarcity in the market, owing to some trouble at the source of supply in Mexico. *Ismene calathina* and Amaryllises may be lifted and kept dry

over winter, or in slightly moist earth or sand; in a temperature of over 45°. Tuberous Ipomæas, Erythrina roots and Daturas that have been grown and flowered in summer, may now be shortened back and kept dry over winter, or, better yet, in moist earth, or laid on an earthen floor.

G. C.

Silenes.—Among these are pretty perennials, biennials and annuals; nearly all are hardy, easy of culture, and excellent plants for the rock-garden. A soil composed of loam, peat and sand is most favorable for their growth. They will not thrive in heavy soil or in the shade. They can be propagated by seeds, division or by cuttings. *S. acaulis* forms a neat evergreen cushion, with white flowers. *S. alpestris* grows about six inches high, and its white flowers are borne in abundance. *S. Elizabethæ* is a rare and beautiful species, rather tender, with large, deep rose-colored flowers. *S. Hookeri* has large pink flowers, two inches or more in diameter. Coming from California, it is not hardy here. *S. maritima, fl. pl.*, is a very free-flowering, double white variety, like the type in every other way. It is a neat trailer, its handsome, glaucous-green foliage clothing the stones completely. *S. pendula, var. compacta*, is the variety so much used in England for spring bedding. It is most effective when planted amongst yellow Tulips or blue Hyacinths. *S. Pennsylvanica* is a common native, but very pretty species. *S. Schafta* flowers at a season of the year when all other Silenes are past. A mass of it in the rock-garden here was strikingly beautiful in late August. It is one of the best, and although it winter-killed with me in New Jersey, it proves quite hardy here. The flowers are a lovely pink-purple. *S. Virginica*, the Fire Pink, is one of the most striking, and one of the few hardy plants with clear scarlet flowers.

T. D. Hatfield.

Wellesley, Mass.

Rose Cuttings.—It is now claimed that blind wood of Roses, if made into cuttings, will produce equally floriferous plants with those made from flowering shoots of the same varieties, and, judging from some extended tests made by good growers, this seems to be an established fact. This view is exactly opposite to that held by many growers in former years, and though contrary to the traditions of the trade, yet it seems to be quite reasonable. When blind shoots are used for this purpose, they should be clean, healthy pieces, such as are frequently produced by Catherine Mermet, The Bride and other varieties during the winter; for, though both of the above-mentioned Roses are very free in regard to bloom, they also make a considerable amount of non-flowering wood in a season, and this growth, when in a healthy condition, makes a desirable addition to the cutting-bench. There are some conservative growers who still prefer to make cuttings only from shoots which have produced flowers, but it frequently happens that some difficulty is found in procuring enough wood of this class at the time when it is wanted most, and therefore it is advisable to put in all the healthy wood at command, as weak or sickly plants can easily be discarded if any such are found at the time of planting. And when it is thought desirable to have a stock of young Roses for early sales, or for summer use, it will be found best to commence putting in cuttings as soon as they can be obtained in the fall; for instance, in October or November, or earlier if suitable wood is to be had without injury to the crop, because plants struck at this time, and shifted on as it becomes necessary, will be in good condition for early planting the following season. Of course these remarks will be understood to apply especially to Roses of the Tea class, such as are used for forcing.

Philadelphia.

W. —.

Gladiolus-flowered Cannas.—We quote the following from *The Garden*, London, in addition to what was said last week concerning these plants, because we believe they have a most promising future:

"This very expressive name has been given to a new class of Cannas conspicuous for the beauty of their flowers, which much resemble those of a Gladiolus in form and size. Hitherto, with a few exceptions, the Cannas have been grown more for the beauty of their foliage, which imparts to them a very dignified aspect, and is, moreover, quite distinct. Usually, plants which are grown for beauty of foliage alone, do not produce very striking flowers, and it has been so for many years with the Cannas, but these new varieties, which are of French origin, show evidence of a rapid and marked improvement, which probably will continue, and we may shortly look for something quite

Fig. 62.—*Pinus ponderosa pendula*, at Wodenethe.—See page 392.

startling in this direction. We recently noted some in flower at Tottenham, especially good being Victor Hugo, a variety with dark leaves, and large, bright red flowers, equal in size to those of Canna Ehmanni, and Edourd André, with flowers of a deeper red, but quite as large; Queen Victoria, with spotted

yellow flowers, was also good. The Cannas do not receive half the attention they deserve. Where their culture is practicable, they are most effective in the open air in summer, and serve an admirable purpose by carrying the eye gradually upwards from the dwarfer subjects usually employed in the

embellishment of the flower garden to the taller forms of tree and shrub life. They will also be found very useful when grown as specimens in pots for conservatory decoration, and, by reason of the hardiness and texture of the foliage, their beauty and freshness last a long time. We owe all the best of our Cannas to the French, and it is to be hoped they will continue in their good work of improvement, and give us some varieties that, for beauty of flower, will eclipse anything previously seen. The varieties above referred to amply show the capability of improvement."

Plant Notes.

The Weeping *Pinus ponderosa*.

THE illustration upon page 391 represents one of the most interesting coniferous trees which can be found in the Eastern States. It is a specimen, and the only specimen which is known, of the well known Yellow Pine of the Pacific forests (*Pinus ponderosa*), in which all the branches have assumed a decided and permanent weeping habit, giving to this individual a grace of outline quite unknown to the Yellow Pine in its normal form. This tree, with a number of others, was imported from the Knap Hill Nurseries in England in 1851, when only a few inches high, and planted by Mr. Henry Winthrop Sargent in his garden at Wodenethe, in Fishkill-on-Hudson, in this State. It is now fifty-nine feet in height, with a trunk diameter, three feet from the ground, of twenty-one and a half inches, and it is still growing rapidly. The origin of the seed from which this tree was raised is unknown, although it no doubt came from Oregon or California, as the seeds of trees were not collected on the mountains of Colorado until several years after this Pine had been planted on the banks of the Hudson. Its perfect hardiness, therefore, must be taken as an exception to the now generally acknowledged fact that the Conifers of the Pacific-coast region are unable to support, for any length of time, the climate of the northern Atlantic States.

But the real interest in this tree is not found in its graceful and unusual habit, or in its hardiness, but in the fact that it was planted and beloved by the man to whom, more than to any other, Americans owe their knowledge of cultivated trees, and who, for nearly half a century, devoted himself, with an energy and enthusiasm which no disappointment ever dulled, to experiments in tree culture. The friend and pupil of Downing, he extended the fame of his master, and by his example, his precepts and advice inspired what is best in American gardening of to-day. This pine may well serve to keep green the memory of Henry Winthrop Sargent, and to remind the present generation how much it owes to his disinterested labors in their behalf.

A picture of this tree was published in the *Gardeners' Chronicle*, of London, August 24th, 1878, from a photograph taken in that year. Our illustration is from a recent photograph by Mrs. Winthrop Sargent, to whom we are indebted for its use. C. S. S.

Origin of the Le Conte Pear.

AT page 268 of the Report of the United States Agricultural Department for 1886 Mr. John L. Harden, of Walthourville, Ga., makes the following statement in regard to the origin of this Pear:

"Major John Le Conte, of New York City (and afterwards of Philadelphia), in the year 1850 had a number of fruit trees and other plants put up for his niece (Mrs. J. L. C. Harden, my mother), of Liberty County, Ga., at a nursery in New York or Philadelphia (most probably New York), and among them was a rooted cutting of what was marked 'Chinese Sand Pear.' Major Le Conte was informed by the proprietor of the nursery that the Pear was only fit for preserving, as it never matured in this country. Contrary, however, to expectation, it matured in Liberty County, and proved to be a fine, productive Pear. The original tree is now owned by my mother's heirs, and is still vigorous, although not cultivated in any way, and produces from ten to twenty bushels each year."

This statement enables me to clear up the mystery of its

origin. Some six or seven years previous to 1850 my brother, Mr. Thomas Hogg, obtained from Messrs. Potter Bros., of Providence, R. I., a plant of *Pyrus sinensis*, the Chinese Sand Pear, or Snow Pear, as it is called by some. This plant was grafted on a stock of *Pyrus communis*, our common Pear. It was planted out in the nursery at Yorkville in a plot of ground devoted to testing new varieties of fruit trees, and was surrounded by a number of Pear trees of different varieties. In due course of time the tree fruited, and from the seeds thus obtained young trees were grown, one of which was given to Major Le Conte, and is no doubt the tree noticed by Mr. Harden. It is doubtless a hybrid, produced by the pollination of a flower of the Sand Pear with the pollen of some one of the surrounding Pear trees. I remember that there was one tree near by with fruit very much the shape and size of the Le Conte, but I cannot recall its name. The Sand Pear tree we had bore large, apple-shaped fruit, the stalk being deeply inserted, of a deep orange color, somewhat russeted and thickly studded with raised brown dots. The skin felt as though sanded over by these dots. Otherwise the fruit was very handsome to look at. Dorr and Dr. Lindley describe the fruit of the Sand Pear as warty, bony and gritty, but the fruit of our tree was in no wise warty or bony, being only gritty. It was not edible, but made a fairly good preserve, and always ripened its fruit. Mr. Harden is mistaken in saying that Major Le Conte was told that it would not ripen its fruit.

Fig. 63.—Malformed Cabbage Leaf.

My opinion is that our climate, or its being grafted on a common Pear stock, had something to do with ameliorating the character of the tree we had, and rendered it more susceptible of hybridization. It is a very unusual instance of the effects of hybridization, as the product is so very unlike the mother tree, that if the latter were not known there would be great doubts as to its being one of the parents, judging by the fruits.

I may add that the Sand Pear is quite an ornamental tree. It has long shoots of a greenish, changing to purple, color, thickly dotted with white spots; large, lucid, almost evergreen leaves; and large white flowers slightly tinged with pink. James Hogg.

Tubular Cabbage Leaves.

THE interesting monstrosity of Cabbage leaf described and illustrated in GARDEN AND FOREST, p. 296, is essentially the same, evidently, as the *Brassica oleracea, costata Nepenthiformis* described and figured by the elder De Candolle in *Trans. Lond. Hort. Soc.*, v. 12. A monstrosity of similar character, but involving the whole first true leaf of a Cauliflower plant, was observed by the writer this year. It is here figured. L. H. Bailey.

The Forest.

Forestry in California.—III.

FOREST economy is slow in its returns, a new growth for timber requiring many years, which is discouraging to short-lived man; consequently, men cut forests for commercial purposes, but it is rare, indeed, that a forest is ever planted. So also much of forested land in new countries must be cleared as population increases, irrespective of the demands of commerce and whether the result be health or sickness.

But there is a point, variable according to the climate and topography, beyond which the destruction of forests diminishes the capacity of the country to support population, and, while at first increasing the arable area, in the end diminishes this through the action of torrents in washing the soil from some places and covering others with sand and bowlders, while at the same time the whole country becomes more exposed to extremes of flood and drought and the climate more variable and unfavorable to agriculture, the winds stronger and the springs less reliable and often extinguished.

It is by educating the people in these truths of the effects of excessive and unwise forest destruction that we must hope to

save our forests. The time has come for this intelligent American people to follow the lead of France, Germany, Austria and the civilized powers of the world in averting, by timely measures, a great disaster. I shall now briefly set forth the manner in which the beneficial effects of forests in agriculture are produced.

The normal evaporation from bare land is much in excess of that from lands in woods. An experiment made with two jars of equal size, covered with wire gauze to protect them from flies and insects, one set under a bush and the other in a place sixty feet from the surrounding trees, but thus protected from wind, showed the evaporation in the open to be more than double that under the bush, the exact figures being: bush jar, .863 evaporation; jar in the open, 1.854.

Mr. W. Blore, who made this experiment, calculated that, in the 102 days of average dry season at the Cape of Good Hope, the excess of the evaporation from a burned or bare district over a bush or forest covered one would be 384,000 gallons per acre, or 384,000,000 gallons for a thousand acres.

Other experiments in England show that the evaporation from an open vessel in a room is eight inches in a year, while in a field or open place it is estimated at between thirty and forty inches. The soil in a forest being protected by the trees to a certain extent, and thus under cover, we may infer that evaporation would be less under such conditions than in an exposed place. It is a matter of common observation that roads running alternately through woods and open country remain longest moist in the woods. Railroad cuts show the same difference; houses in forests are damper than those in the open. These facts go to show that evaporation from the soil is slower in a forest than elsewhere. The only exception to this is where water is in excess. The evaporation activity of the trees is then excited to such an extent as to neutralize their protective effect upon the moisture in the soil itself. Thus trees in a swamp have a draining effect, while upon dry soil they will maintain humidity.

Nothing is better authenticated, both by scientific and general observation, than this last effect. In California we have learned to help the soil and maintain moisture by making the soil a mulch for itself by cultivation, that is, by keeping the surface pulverized. But this artificial process is unprofitable upon the steep mountain sides, where our forests are of most importance. Such an attempt would only result in the washing away of what soil there is on the mountains. In this connection it may be well to note the value of thorough cultivation. The driest soil contains thirteen per cent. of moisture. Schubler's experiments show that soil that weighs about a thousand tons per acre, when thoroughly pulverized and completely dried, will absorb from the atmosphere in twenty-four hours:

Sandy clay,	- - -	Twenty-six tons of water.
Loamy "	- - -	Thirty " " "
Stiff "	- - -	Thirty-six " " "
Garden mould,	- - -	Forty-five " " "

We are all familiar with the absorptive capacity of common salt. Carbonate of potash has also notable affinity for moisture, but it is the humus of the forest that possesses this power more than any other soil, absorbing to again give off from two to four times its weight in water. Forests mulch the ground under them. It therefore becomes plain, that forest fires, when not destructive to the trees, diminish the capacity of the forest for retaining moisture. The trees also protect the earth under them from the heat of the sun. Soil in the open is raised in temperature by the sun at a depth of one foot, fifteen degrees more than in a forest; consequently, the abstraction of moisture is correspondingly larger in the open. The difference is as 130 to 1,000 in favor of the forest. On the other hand, the experiments cited by Marsh show that in winter soil has been frozen to a depth of six feet on a bare knoll, while in the adjoining forest the soil was uniformly above the freezing point. This is most important in California in our high mountains, for rains upon frozen ground must run off without penetrating. So bare places would not act as reservoirs for later use, while the forested land would. Forests protecting land from excessive heat, protect the snows from rapid melting. The last place from which snow disappears, at the same elevation and isothermal line, is the forest. To the irrigators of parts of central and southern California this is of great importance, for, with the forests, the snow water of spring and early summer is long maintained, while without them the melting of the snow must be more sudden and the water resulting from it flow off in floods, so it is dissipated and the life-giving water is gone when most needed.

Another effect of forest action is that the snows in them

melt from the ground side most and thus can reach the conduits that supply the springs, while snow upon frozen ground melts from above and runs off rapidly. The desiccating effect of winds is often great. Our dry winds in this State do much damage to fruit trees and dry the grain in the milk, diminishing the crop. Forests have a modifying influence upon such winds. In fact, a dry wind cannot originate in a frosted country, and, as it passes over forests, is diminished in intensity; even a belt of trees will have a pronounced protective influence on crops and trees to leeward of them and for some distance to windward also, for the trees bank up the air on this side, as is known by hunters, who, in striking a light, place the shelter of their hand on the lee side, having the light in the direction from which the wind comes.

Trees protecting the ground from the rapid radiation of heat, prevalent in bare places, diminish frosts. Thus a plant under shelter of a tree is less likely to be frozen than if it were in the open; but trees protect in this respect in another way. Megucher's experiments in Lombardy show that trees, like animals, maintain a constant temperature, that is somewhat modified, doubtless, as it is in animals, by hibernation. This temperature for trees is fifty-four degrees; forests in a country, therefore, have a similar effect to the sea. They maintain a more even degree of humidity and of temperature and equalize the climate.

The deposit of dew is more copious upon vegetation than it is upon the soil. Experiments show the difference to be more than double; the exact figures are: for grass, 4.75; for a white surface, 2.00.

In walking through grass or bushes after a dew the moisture will be apparent as compared to bare land. Fogs and mists are to a considerable extent condensed by the foliage of bushes and trees, and drip from them to the ground. On misty mornings I have frequently been wet through when walking in the chapparal of the Sierra Madres, while on the bare hillsides no moisture was visible. At Santa Monica where I spend the summer, on foggy days the trees may be observed to drip with water, and in thick fogs the drip is so continuous as to suggest rain as it drops on the fallen leaves.

Santa Monica, Cal.

Correspondence.

Forest Planting in New England.

To the Editor of GARDEN AND FOREST:

Sir.—I have on a farm here some acres of land affording but poor pasturage, some of which is grown to bushes and some little clear land formerly devoted to grass. I have been led by GARDEN AND FOREST to consider the advisability of devoting the land to forest plantations of Ash, Chestnut or White Pine. If I am not trespassing too much on your time and kindness, will you please tell me what books or publications would be of service to me in learning the best method of planting and the result of experiments made in the planting of forests in New England.

My land differs from the sandy soil of the Cape, where I think successful experiments have been made, in being stronger and of a kind considered good grass land. Whom would you recommend as an expert in the matter?

Truly yours,

William Simes.

Petersham, Mass.

[There is no American Manual of Arboriculture, and the foreign works upon this subject, based upon conditions dissimilar to those which prevail in this country, have little practical value here. The general principles of tree planting, however, applicable to the United States as well as to Europe, will be found in "The Forester," by James Brown, published in Edinburgh, 1882, and in "Arboriculture," by John Grigor, Edinburgh, 1868. There are papers relating to tree planting in Massachusetts, in the Reports of the Secretary of the State Board of Agriculture of that State for 1875, 1878, 1882 and 1885, and there is much information upon this subject, valuable and otherwise, scattered through the reports of Agricultural Societies and Boards of Agriculture of almost all the Northern and Western States. The most interesting plantations of forest trees made in Massachusetts are those of White Pine in Middleborough, Raynham and Bridgewater, of which an account will be found in the Transactions of the Massachusetts Horticultural Society for 1885; the Pitch Pine plantations in Orleans and in other towns on Cape Cod, of which a description will be found

in the report of the Connecticut State Board of Agriculture for 1877-78; the large plantations of foreign trees principally Larches, Norway Spruces, Scotch Pines, Oaks and Birches, made by the late Richard S. Fay, near Lynn, and by Mr. Joseph S. Fay, at Wood's Holl. There is also an instructive plantation of European Larches on Mr. J. D. W. French's farm in North Andover, which was described in the first issue of this journal; and in East Greenwich, Rhode Island, large plantations of Larch and White Pine have been made during the last ten years upon the farm of Mr. H. G. Russell, where these trees have made a satisfactory growth upon sterile and apparently barren land. Land which is strong enough to grow good white ash is too good for pine, which will grow to a large size on dry, gravelly ridges. The land which our correspondent describes would probably grow either chestnut or hickory, both valuable woods, for which there is an active and increasing demand. Chestnut and Hickory trees can be raised by planting the seed where the trees are to remain, and are, therefore, more cheaply raised than Ash or White Pine, which must be transplanted from the nursery. If the land in question is fenced, so that animals can be kept off of it, and planted in the spring with chestnuts and hickory nuts, it will be covered in a few years with these trees, and many others, which will spring up spontaneously in great variety, as soon as cattle are kept out. The nuts for planting should be gathered as soon as ripe and at once mixed with sand to prevent them from drying, as drying destroys their power to germinate, and stored in a cellar from which the frost is excluded. In the spring, when the frost is out of the ground, a man can plant the nuts very rapidly by making a hole about an inch deep, or a little deeper for large nuts, with an ordinary walking-stick, dropping a nut into the hole and then pressing down the soil over it with his foot. The nuts should be planted three or four feet apart, but when the ground is very rough and rocky, they will have to be put in without regard to exact distances and wherever the best soil can be found.

There is no man in the United States who has had a longer and more varied experience in tree planting than Mr. Robert Douglas, of Waukegan, Illinois, and his advice in such matters can be adopted in perfect confidence.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—Black Walnut is not native north of Niagara, but has been raised and produces nuts as far as Quebec. Will the wood of this or any other tree be likely to prove sufficiently sound for manufacturing purposes when grown north of its proper habitat? There is no experience in Canada to show this.

Norwood, Canada.

T. M. Grover.

[Trees can generally be induced to grow in cultivation much further north—that is, in a colder climate—than that in which they are found growing spontaneously, and when the change is not too great they may produce sound timber. The continental distribution of plants being regulated, to a large extent, by temperature and moisture, the fact that any tree, like the Black Walnut, for example, is not found growing spontaneously north of a certain latitude, shows that this is the limit where, unaided by man, this particular tree has been able to maintain itself in the struggle for existence, which is constantly going on between all organized beings; and that if moved beyond that limit and deprived of man's constant assistance, it will be in great danger of being compelled to succumb, sooner or later, to unfavorable conditions. For this reason it is wise to select the native trees of any region to plant for timber in that region. It is impossible to predict that any others will reach maturity and produce valuable material.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—It gives me pleasure to note that GARDEN AND FOREST constantly advocates the use of more natural forms in the ar-

range of plants for the embellishment of public and private grounds. Such articles as that on the planting of hardy bulbs in the grass cannot fail to bear good fruit. How many barren spots there are that need such a brightening up at spring-time as only a few Daffodils can give them. And why should not some of our native hardy plants be used in such places; for instance, the Blood-root, Dicentra or Hepatica, and for later blooming the Columbine, Mandrake, Meadow Lilies, Golden-rod and Asters. I have found that these wild beauties easily adapt themselves to a place seemingly most unfavorable for their life and growth, so I can easily imagine what might be accomplished were they distributed over larger grounds. The woods are not always easy of access, but we can bring a bit of them close to our homes.

I have noticed at Kew what might be termed a perpetual garden, which your readers might easily imitate, or even improve upon, by making a still bolder departure from the conventional. There is a serpentine walk, lined on either side by banks of rock-work four or five feet high. These are planted with English hardy plants as well as Lilies and other bulbs, and many of those that come under the general head of alpine plants. They are scattered about quite naturally, and are so arranged that there is an abundance of bloom throughout the season. To those possessing rocky grounds this suggests unlimited possibilities in the formation of a natural garden of great beauty, and one that offers a large return for a very little labor.

Brooklyn, N. Y.

H. S. A.

To the Editor of GARDEN AND FOREST :

Sir.—In an interesting article on "Cultivation of Native Ferns," by Robert T. Jackson, in your journal of the 5th inst., some examples are given of "the extreme hardness and vitality of Ferns," to which I can add a perhaps still more remarkable illustration.

About ten years ago a lady living in New Zealand sent me, by mail, covered with a piece of brown wrapping-paper and tied with a string, six roots of New Zealand Ferns. When I received them here in California they were, of course, absolutely dry and apparently absolutely dead; but wishing to test the matter, I poured some tincture of gum camphor into warm water and sprinkled the Ferns with the mixture, leaving them lying upon wet moss for twenty-four hours, after which I planted them in pots. One plant of *Pellaea falcata* commenced to throw up new fronds in a few days after its receipt, and is still growing in my conservatory. I do not remember how much time was occupied in the transit, but I think it was about three months, as the facilities for rapid communication by mail in those days were greatly inferior to those of the present time.

Santa Barbara, California, September, 1888.

Lorenzo G. Yates.

Periodical Literature.

The leading article in *The Cosmopolitan* for August is Mrs. S. B. Herrick's on "The Romance of Roses." The author's aim has been to trace the continuance and explain the strength of that preference for the Rose above all other flowers which has distinguished every people to whom it has been well known; and, together with a great deal of romance, she gives us many interesting facts. The most interesting are perhaps those which reveal the use the Romans of the Empire made of Roses—a use which makes our utmost extravagance seem positive parsimony. When we read of floors carpeted with fresh Roses a foot deep, covered with a fine netting that the guests might walk upon without disturbing them; of a single feast given by Nero, when a sum equivalent to \$100,000 was spent for the Roses alone; of water parties at Baïæ, where "the whole lake of Lucina was covered with Roses, which parted before the moving boats and closed after them as they passed;" of Lucius Verus sleeping upon cushions of net stuffed with freshly-gathered Rose-leaves, and of Heliogabalus demanding that his couches, beds, floors, and even porticoes, should be kept perpetually covered with them—how can we think that we are extravagant in our use of Roses? At first the Roses required in Rome were imported from Egypt, but later on a sufficient supply seems to have been grown in Italy, where, according to Ovid, they were made to bloom twice a year by means of hot water, carried, as other writers explain, in pipes, much after the manner of to-day. The love of mediæval ages for the Rose has become proverbial, and it expressed itself in many court as well as popular customs. For centuries before the reign of Louis XIII. the peers and dukes of France, and even the King of Navarre, were obliged to present Roses, in their season, to the Parliament of France

as a symbol of the suzerainty of the King; and the right to represent them at this ceremony was eagerly disputed for among the highest nobles of the realm. Similar tributes were frequently exacted by minor suzerains, and even in real estate transactions a Rose, or a bushel of Roses, often appeared as part of the payment or an equivalent therefor. The Golden Rose, which the Pope still annually bestows upon some one whom he desires to honor, was first given in 1366. The form of the present was chosen as significant of the fragility and evanescence of life, and the indestructible, incorruptible material as emblematic of the immortality of the soul. At least, Mrs. Herrick tells us, ancient writers thus declare; and, whether it be accurate or not, the explanation is a poetical one. The drawings by the author, which accompany this article, are both faithful and poetic; the others are less good, and the colored plates are beneath criticism.

Blackwood's Magazine for August contains an interesting article called "In a Garden of John Evelyn's" which unites a sketch of Evelyn's life with a description of the garden which he assisted in laying out for a friend—one of the Howard family, who afterwards became the Duke of Norfolk. This garden lies at Chertsey, in Sussex, about thirty miles from London, and in the neighborhood of Wotton, Evelyn's old home. As Pope and Addison worked in the eighteenth century, so Evelyn worked in the seventeenth, and still more influentially, to popularize a love of nature among his countrymen. Pope's and Addison's efforts tended to turn men away from the formal towards the natural style of gardening. In Evelyn's earlier time, landscape gardening, in the meaning we now attach to the word, had not as yet been thought of. Nevertheless the truest love for nature and the most admirable taste characterize all his works on gardening, and the formal gardens which he loved are by no means to be confounded with those which, later in his own century, were mere arrangements of clipped trees and regular walks crowded with a mass of artificial constructions. His taste had been trained, during many years of foreign travel, on the beautiful early gardens of Italy, and something akin to them he tried to produce in England, with a wise regard, however, for differences in climate, habits of life and artistic conditions. The garden at Chertsey is said to be better preserved than most others of its time, and the description given of it in *Blackwood* is certainly most attractive. "It is perhaps an ancient pleasure more than a garden such as belongs to the present day. . . . The growth of years has but added to its charm, and has produced the grandeur of the trees, which must be the chief attraction to a pilgrim to the shrine of 'Sylva Evelyn.' . . . There is as much shade as sunshine around us here. . . . Few signs of modern taste have entered; 'bedding out' and those monsters of horticulture known as *massifs* are unknown. There is not a single ribbon-border anywhere, nor beds of tropical plants. . . . Here is a space set apart for a rose-garden, and the Roses have had their way in it for years. Trellised arbours lead to it, and the entrance is darkened by overhanging clusters. Below the rose-garden the ground slopes to the margin of the stream. . . . There are thickets along the stream and many a winding walk below tall trees and all kinds of flowering shrubs overhanging the stream. We notice fewer brilliant effects than tender colors and sweet scents, except at intervals, where great scarlet Poppies flaunt in the sun, contrasting with yellow Day Lilies, or spires of blue Lupin or white masses of golden Crocus catch the sunshine in early spring. And here and there among their more cultivated sisters there is space for a wild flower to find shelter. . . . Here is a group of Ilex trees, whose shadow falls upon some old brick-work, and flights of stone steps which lead up to the chief attraction and crowning feature of the garden, a broad, grassy terrace, stretching in long perspective for a quarter of a mile. Half way down its length is a semicircular recess and a pool of clearest water covered with Water Lilies and dark with overhanging trees, which hide the entrance to the grotto; . . . and rising over all the splendid group of Firs. . . . On the old walls which bound the terrace on the left there is a delicious mingling of fruit and flowers. . . ."

Recent Plant Portraits.

ONCIDIUM LIETZEI, var. AUREO-MACULATUM. *Gartenflora*, August 15th.

PLAGIANTHUS LYALLI. *Gardeners' Chronicle*, August 25th; a malvaceous shrub or low tree, with handsome white flowers three-fourths of an inch across. This will probably make an

interesting and valuable addition to the list of hardy shrubs which can be cultivated in gardens in our Southern States.

SCHOMBURGKIA TIBICINIS. *Gardeners' Chronicle*, August 25th. *Botanical Magazine*, September:

SPATHOGLOTTIS VIEILLARDI, t. 7,013; native of the Sunda Archipelago and New Caledonia; a robust species, with handsome pale lilac, or nearly white, flowers, two inches across.

Caraguata Andreana, t. 7,014; native of New Grenada; is a showy Bromeliad, discovered by Monsieur Ed. André on the Cordillera of Pasto during his memorable South American journey, and introduced by him into cultivation.

Masdevallia Mooreana, t. 7,015.

NARCISSUS BROUSSONNETII, t. 7,016; "this is a very curious plant. It is just like the white Tazetta Narcissi (*Italicus*, *Panizzianus*, etc.) in habit, leaves, perianth, stamens and pistil, but the corona is very nearly or entirely obliterated. It was carefully studied by the late Jacques Gay, one of the most painstaking botanists who ever lived, and his conclusion was that it ought to be regarded as forming a monotypic genus. It was first found about the beginning of the century in the neighborhood of Mogadore by Broussonnet. Nothing more was heard of it until 1873, when specimens were sent by Dr. Leared to the late Daniel Hanbury. Now it has been introduced alive, and was flowered last winter both at Kew and by Sir E. G. Soder at Flone. It will probably not prove hardy in the open air in England."

ERYTHRONIUM HENDERSONI, t. 7,017, recently described and figured in this journal (p. 317).

Exhibitions.

The Pennsylvania Horticultural Society.

THE fifty-ninth annual exhibition of this society, held in Philadelphia last week, was not as large as some of its predecessors, but for the number of remarkable specimens displayed the show has not been surpassed for several years. Probably the finest plant in the hall was a *Kentia Forsteriana*, exhibited by Wm. Joyce, gardener to Miss Baldwin. Its foliage is very clean and bright and the plant is fully twelve feet high. Specimen plants of *Latania Borbonica*, *Cycas circinalis* and *Pandanus Veitchii* followed hard after this in the order of merit. A remarkable *Cissus discolor*, covering an oval frame four feet high, well furnished with foliage, some of the leaves measuring quite nine inches long, was exhibited by Robert Wark, gardener to C. H. Clark. An *Alamanda Schottii*, also grown on a frame and well set with flowers and buds, showed blooms quite four and a half inches in diameter. It was exhibited by Wm. Frederick, gardener to W. W. Frazier, of Jenkintown. Thomas Long, gardener to A. J. Drexel, exhibited a well-grown specimen of that miniature Palm, *Livingstonia Altissima*, and its beauty made visitors regret that it was so scarce and costly. A specimen of *Cocos Weddelliana*, exhibited by Mr. Joyce, is six feet high and in fine condition. Chas. Ball contributed a well-colored plant of the variegated Pineapple. Three fine plants were shown of *Davallia Fijensis*, a Fern that was grown by a Philadelphia florist for ten years before it was named and distributed by Wm. Bull. It was sent to the Philadelphian by a friend who visited the Fiji Islands.

The collection of fifty Caladiums from "Wootton," the country-seat of Geo. W. Childs, were fine examples of good culture. John M. Hughes, the gardener to Mr. Childs, deserves great credit for this display, as it occupied nearly one side of the hall. Hugh Graham's son received a first premium for six fine specimen plants of Maranta, and Chas. D. Ball took first for a grand collection of twenty-five specimen Ferns, including the finest Adiantums, Davallias and Gleichenias.

Henry A. Dreer exhibited *Aristolochia elegans*, a novelty from Brazil. It is a grand vine and certain to become popular, if, as is claimed, it will bloom the same season from seed sown in the open air in spring. Mr. Dreer also exhibited the finest collection of tuberous-rooted Begonias ever seen in Philadelphia. Many of the flowers measured four and one-half inches in diameter.

The tank of Water-lilies contained examples of *Nymphaea Zanzibarensis*, *N. Devonensis* and *Nelumbium speciosum*, and a smaller tank was filled with the comparatively new *Pontederia Crassipes*, from British Guiana, with blooms resembling at first sight a pale blue Iris. Cut Roses of admirable quality for the season were exhibited by Edwin Lonsdale, Craig & Bro., Pennock Bros. and Coles & Whiteley. Some Madame Cuisins were particularly fine. The Gloxinias and Petunias exhibited by Henry A. Dreer and the daintily arranged Pansies

and single Dahlias by O. R. Kreinberg were well worth the attention they received.

The wild flowers collected by Allen Barr were well chosen, but they lost some of their educational value because they were not named.

The Cattleya El Dorado, which is a beautiful pink, was thought by many retail florists to be one of the most desirable for use in the arrangement of flowers. Pennock Bros. exhibited a large urn and Heron & Nesbit a vase of cut flowers, both of which received special premiums, and Miss Anna A. Bisset won the first prize for a cross and wreath. Archibald Lawson, gardener to H. H. Houston, Chestnut Hill, exhibited some very handsome grapes, the clusters of White Nice, Santa Cruz, Prince Albert and White Syrian being particularly fine.

The attendance was only "fair." It is strange that an exhibition as good as this should ever lack a generous attendance in any of our large cities. But the question how to make horticultural exhibitions meet expenses, is one that too many of our oldest and best societies are still compelled to consider.

H. H. Battles.

Notes.

Florida Persimmons are sold as a novelty by New York fruiterers for 60 cts. a dozen.

Autumn leaves from New Jersey thickets are tastefully combined by New York florists, and sold by the dozen or the cluster.

Dill and Fennel have never been brought in such quantities to the New York markets as they have this season. There is also an increased demand for Tarragon.

Mr. William Court, well known to many American horticulturists as an agent of the Veitch Nurseries, died suddenly of apoplexy, in London, on the 17th of last month.

The finest Crawford Peaches are now coming from Baltimore, where they have been kept back in cold storage-houses. They sell for \$4 a crate, and for 75 cts. and \$1 a dozen.

Mr. J. A. Lintner estimates that there are in the United States 1,000 species of insects which are injurious to fruits, and of these 210 are known to live at the expense of the Apple-tree.

For some reason trees and shrubs are later than usual in assuming their autumn colors, but for a week past *Berberis Thunbergii* and *B. Sinensis* have fairly glowed with the brightness of their orange and scarlet.

A Pearl River plantsman is bleaching the tops of Russia Turnips, which are a hot-house delicacy abroad, and which are prepared for the table much the same as Sea-kale. These and Cauliflower, also forced in hot-houses, will be in market about Christmas.

Professor James argues that it is quite as legitimate to expend Federal money to prevent the soil from flowing down mountain sides and filling up rivers as it is to expend money for clearing out their channels when once filled; and that it ought to be permissible to expend Federal money to protect the stream itself, if it be proper to stock and re-stock it with fish.

Juglans Manchurica is a most promising nut tree from Japan. A tree in the Arnold Arboretum, from seed planted in the fall of 1879, has this year borne two bushels of nuts. The fruit is larger, more nearly spherical and less rough than our common butternut and is of very good flavor. The nuts are borne in clusters with from six to thirteen together. The tree has borne now for five years, and, besides the valuable crop it yields, it gives good promise as an ornamental tree.

The *Tribune*, of San Luis Obispo County, California, reports some wonderful yields of Onions in the valley of the Arroyo Grande. The product of one acre was weighed, and amounted to 66,905 pounds, or more than thirty-three tons. This would be by measurement 1,194½ bushels. One of the Onions measured seventeen inches in circumference. A Radish in the same valley is said to have weighed thirteen pounds, being twenty-one inches in girth and thirty-eight inches long.

The report of Mr. J. H. Hart, the new superintendent of the Trinidad Botanic Garden, for the year 1887, has appeared. This is one of the richest, as it is the oldest, of the botanic gardens in the British West Indies, having been continuously maintained during a period of seventy years. Its usefulness is now likely to be greatly increased under Mr. Hart's management, which is first directed properly to the permanent establishment and arrangement of an herbarium, without which no botanic garden can be operated. The task is the more important as Trinidad possesses a flora of great variety, combin-

ing West Indian and South American plants, besides many indigenous to the island.

Experiments recently made by Prof. Schubeler, a Norwegian plant-geographer, confirm the belief that most plants produce much larger and heavier seeds in high northern latitudes than in those further south, the difference resulting from the prolonged influence of light consequent upon the length of the summer day at the far north. One of the most remarkable instances he noted was that of Dwarf Beans, which gained sixty per cent. in weight when taken from Christiania to Drontheim, a distance of no more than four degrees; and another was that of Thyme, which, taken from Lyons to Drontheim, gained seventy-one per cent. All our cereals likewise show a marked increase in weight when grown at the far north.

The new museum building of the Royal Botanical Garden in Breslau, Germany, was recently opened. With its fittings it cost about \$50,000, and it contains, in addition to the large rooms in which the collections are arranged, a library, a lecture-room with seats for 100 persons, an apartment for the Institute of Plant Physiology, another of a large size for microscopical work, and a number of smaller ones devoted to different purposes. The collections include an herbarium; a collection of woods, seeds, fruits, specimens prepared in alcohol, and pictures of the most useful exotic plants, so arranged and catalogued that the general public may be interested and instructed; a colonial botanical collection; a phyto-palæontological collection; and a collection of cryptogams. The Director, Professor Engler, invites correspondence with a view to the exchange of duplicates.

Bulletin No. 2, just issued by the Forestry Division of the Department of Agriculture, contains several interesting papers grouped together under the general title of the Forest Conditions of the Rocky Mountains. Some idea of the depredations upon the National Forests, and the powerlessness of government officials to prevent them, can be formed from the extracts here given from Reports of the Commissioners of the Land Office. Professor James writes of the relations of the Government to the Forests, showing that there is abundant precedent, if any were needed, to justify state and national legislation for protecting our forests. The Report of Colonel Ensign gives an account of the forests in the various states and territories in the Rocky Mountain region. George B. Sudworth writes of the forest flora of the region, giving an artificial key to facilitate the identification of the principal species, a work which would have been more useful if all the known species had been included. The needs of the Yellowstone Park are considered by Dr. Arnold Hague, and Mr. Abbot Kinney writes of the forests of some of the Southern counties of California. A summary of legislation for the preservation of timber or forests on the public domain is given by Mr. N. H. Egleston. The effect of the climate of Colorado upon trees is discussed by Mr. George H. Parsons, and Mr. Fernow writes of the formation and preservation of snow slides and avalanches.

Writing from Rome, in the *Christian Register*, Miss Augusta Larned says: "One of the most beautiful of the old cloister gardens is attached to the sumptuous church of St. Paul's Outside the Walls. . . . The whole garden is filled with Roses and sweet herbs. In the middle stand the old well and the sun-dial, but everywhere the pink buds and blossoms are turned towards the sun. The midday warmth brought the odors of Lavender, Rosemary and Mint—scents all the brotherhoods seem to love by instinct. Such depths upon depths of peace and quietude filled this monkish Rose-garden I felt I could sit there for hours and muse on a skull without getting too strong an odor of our mortality. For the glorious Italian spring triumphed over death and decay. . . . The prettiest monastic garden I have seen in Rome adjoins the church of San Pietro in Vincoli, where the 'Moses' of Michael Angelo and the 'Saint Margaret' of Guercino are to be seen. . . . The monastery is now turned into a school for engineers; but the polite attendant is always ready to open the glass door and let you into a grassy nook planted with tall old Orange trees, covered with the golden fruit, into which the Banksia Rose has clambered with a perfect tempest of blossoms, while spring flowers and blooming shrubs fill it to overflowing, run riot over the paths, and paint themselves in vast nosegays against the dark green and golden background. A pair of rooks were fluttering in the shrubbery, the first I had seen, and bright green lizards slipped away between the stones of the old wall. The silence and freshness were indescribable; and, as usual, the vanished brotherhood had left a savor of sweet, old-fashioned herbs behind them."

Sentimental Objections to Felling Trees.—II.

WE spoke recently of that unwise and sentimental affection for trees, which so often interferes with their removal when removal would mean a conspicuous increase in the beauty of their surroundings; and we argued that its false basis is shown by the fact, that it is as often exhibited in the case of decayed and unsightly trees, as in the case of those which, in themselves, have a clear title to admiration.

But the most unfortunate effect of this unwise affection remains to be mentioned. The spirit which condemns the axe when the interests of general beauty require it to be raised, refuses it likewise when the interests of the trees themselves make the demand. Every walk we take through public park or private grounds, shows us not only many cases where beauty of general effect is injured by superfluous trees, but as many where the trees themselves are injured by overcrowding. Trees which have started spontaneously, or have been carefully planted by a landscape-gardener, in such a way that while young they agreeably clothed the spot and usefully nursed one another, have been allowed to grow into spindling groves or tangled thickets, which are not beautiful as a whole and contain not a single satisfactory specimen of tree-development.

Here, for example, is a solid clump which has no beauty of outline and no variety of light and shadow, and in which the colors of the different species are mixed in a confusion that is not true contrast. Thinned out in time, we might have had instead a smaller number of fine specimens, each graceful in form, each contrasting agreeably in color with its neighbors, and all together making a group or a little wood which would have pleased not only by its beautiful outlines, but by its evidence of healthy growth and luxuriant development. Here, again, is a line of trees which were intended to form a screen to shut out some unsightly object or to conceal the limits of the place. When first planted it did form such a screen, although of inconsiderable height, and with judicious thinning it might have remained a screen while its height increased. But

left unthinned it has grown into a spindling row of bare stems, which carry poorly developed heads of foliage far in the upper air, while between them the undesirable object can be clearly seen. In still another place we find two or three trees growing so close together that their branches meet and the growth of each has been checked on the side towards the other. Of course when they are of the same, or of related, species, and stand very near indeed together, the effect may be agreeable, as being the effect of a single large head, supported by two or three stems. But even when they are of the same species the effect is often bad if the stems are so far apart that we clearly realize we have two or three poorly developed specimens where we might have had a single one in beautiful development. And it is a distressing effect indeed when the trees are of different species, and inharmonious one with the other. Quite as often as not this is the case when man's hand has done the planting. It is no uncommon thing, for example, to find instances where a tapering evergreen and a round-headed deciduous tree have been allowed to grow so close together that their alien forms and colors and textures are absolutely welded together in a union as unnatural to the mind as displeasing to the eye.

It is no new grief to which we thus give voice. Doubtless there has never been a time when, by unthinking persons, it was not regarded as, under any circumstances, a crime to cut down a tree. Certainly the literature of gardening art echoes the complaint of the landscape-artist of to-day, that no difficulty with which he has to cope is as great as the difficulty of making an owner thin out his plantations at the proper time and in the proper way. Brown, the famous English landscape-gardener of the last century, has for generations been bitterly abused for forming close, round, hard clumps of trees and spotting them about on lawn and meadow. But there is no doubt that he intended these clumps to be thinned, so that they might eventually resolve themselves into lighter, more varied and more graceful groups. Therefore, when we read of "Brown's clumps" as synonyms for what should be avoided by the planter of to-day, it is not Brown himself but his clients who are really put in the pillory.

It should be remembered that no landscape-gardener can protect himself against a similar fate by planting only those trees which he would like to see in the full-grown group or wood of later years. In the first place, few owners would be content to see the spot for a long period merely dotted over with small, isolated trees; in the second place, young trees must often be planted closely for mutual protection against wind and cold; and in the third place, as no one can predict with accuracy how any given tree will grow, a margin must be left against possible contingencies, not only of life and death, but of peculiarity in development. A planter can hardly imagine in detail the group he wants, and then plant for that group and for nothing else. The best he can do is to decide upon the general size and character of his group; plant in such a way that the probability of getting something near to it in effect will be insured; and then watch his plantation, and thin it out in accordance, on the one hand, with his own wishes, and, on the other hand, with the peculiarities of his developing trees.

Of course such a process as this needs care and thought and taste. But it is just this fact that we desire to impress upon our readers—only by the exercise of care and thought and taste, not only in the act of planting but continually afterwards, can really beautiful results be achieved in any branch of gardening art. After a plantation is made, then the real work of creating it has merely begun; this work must be prolonged for many years, to preserve the beauty of the trees as individuals, no less than to preserve the beauty of the general effect of the scene; and it must very often consist in larger part of the judicious cutting out of individuals which are not only superfluous but detrimental. Yet the hardest task of an artist is to persuade an owner to cut down trees which were never intended long to remain;

and generally it is harder still for an owner to persuade himself to sacrifice a tree of his own planting, even though, by his own confession, it would be far better out of the way.

In the upper part of the lower Michigan peninsula and in the upper peninsula are numerous sandy, barren plains, sometimes called Jack Pine Plains from the prevalence of the Jack Pine (*Pinus Banksiana*) upon them. The largest of these barrens occupies several hundred square miles, and there are others nearly as large. It is believed that these barrens are due to the continual burning of the forest, originally, perhaps, first prostrated by tornadoes. The surface is almost entirely destitute of vegetable-mould; and often it is nothing but a mass of shifting sand, upon which plants are unable to obtain a foothold. The cheapness of these lands has had the unfortunate effect of inducing many emigrants to settle upon them. Hundreds of abandoned homes testify to their worthlessness for agriculture, and stand as witnesses of misdirected labor and disappointed hopes. It is now, however, proposed by the State of Michigan to demonstrate by scientific experiment the value or the worthlessness of these Jack Pine lands. The State Board of Agriculture has established an experimental farm upon land given for the purpose by the Michigan Central Railroad corporation near Grayling, in Crawford County, in the heart of the Jack Pine region. The problem to be solved, as stated by Professor R. C. Kedzie in Bulletin No. 37, from the Experiment Station connected with the Agricultural College of Michigan, which is devoted to this subject, is this: "With a light, sandy soil of very porous quality, in a northern climate subject to late frosts in spring and early frosts in autumn, and liable to midsummer drought, with no fertilizers except marl, salt and plaster, can any methods of tillage or kinds of crops bring these plains into profitable cultivation for ordinary farming, stock-raising, or fruit production?" A thousand years of tree growth, if fires are kept away, may restore some of the lost fertility to these lands, but that any method more rapid in its workings can avail to make them profitably productive, hardly seems probable—a view which more than one settler who has seen his hard-earned savings melt away in an effort to make this land bear fruit, will, we imagine, gladly indorse. It is right, however, to demonstrate by actual experiments, carried on by trained investigators, whether such lands are really worthless, lest the tide of emigration, beguiled by offers of cheap homes, may still continue to press in upon these barren sands.

The following remarkable statement, which has been going the rounds of several of the special journals devoted to the lumber industry of the country, will give some idea of the popular ignorance in regard to trees in this country. The tree referred to is the *Virgilia*, or Yellow-wood, of which a description and illustration were published in this journal on the 18th of April. The *Virgilia* is a rare tree in a wild state, although it is not confined to the neighborhood of Nashville, being found more or less abundantly from Kentucky to Cherokee County in North Carolina, and it is now one of the most generally planted and best known ornamental trees in the Northern States:

Within a radius of sixty miles of Nashville, Tenn., there is found a tree that is supposed to be the shittim wood of Bible fame. Celebrated botanists from all over the country have examined the trees and agree that they grow nowhere else on the globe. They have decided that it is the shittim wood of which the tabernacle was constructed, mention of which is made several times in the Bible. The tree is medium-sized, with very dark, smooth bark, and the wood is of a bright gold color. In early spring the trees are laden with long white blossoms, closely resembling great ostrich plumes. There seems to be no doubt about the identity of the trees, and it is remarkable that they are found only in this small area, and so few at that.

A California Garden.

TRAVELERS who visit the Hotel del Monte, at Monterey, are always interested in the strange garden filled with curious forms of vegetable life, generally spoken of as the "Arizona Garden," which the proprietors of this establishment have caused to be collected there from the extreme southern parts of the State and from Arizona.

Our illustration of a part of this garden upon page 403, gives an idea how succulent plants can be grouped together harmoniously, and of the value of such plants in a dry climate like that of California, where green turf cannot be maintained during the summer months without constant watering. The two tall cylindrical plants on the right and left of the picture are young specimens of the tallest of all the Cactus family, *Cereus giganteus*; between these, in the background, is a plant of the noble desert Palm of southern California, *Washingtonia filifera*; and still further in the background may be seen part of the group of Monterey Pines (*Pinus insignis*) which surround the hotel—one of the very few natural growths of this tree—which is one of the least widely distributed of American Pines, although it is now, however, very generally cultivated in the Pacific States and in central and southern Europe.

The Serpent Mound Park.

THE traveler who happens to be passing along the excellent turnpike from Hillsboro to Locust Grove, in Adams County, Ohio, is likely to be surprised when his attention is called to a prominently displayed sign-board, near the eastern end of Brush Creek bridge, with the legend: "Entrance to Serpent Mound Park." One is not prepared for any such announcement. The surrounding country gives no suggestion of a park, to one who drives for miles through a succession of thrifty farms, and an occasional, sleepy, cross-roads village. If we accept the implied invitation of the sign-board, and enter the grounds, other notices, conspicuously posted for our guidance, will be observed, and naturally we follow the pointing of one which directs to "The Serpent." A winding road leads to the summit of a broad plateau that, at present, is anything but park-like, for reasons to be mentioned later, but still every vestige of the former farm surroundings is wanting. The old worm fences, with their wealth of weeds, have been removed, and in their stead many small trees of different species have been recently planted. But the claim of the spot to be considered a park does not rest upon this small showing; finished pleasure grounds are not lacking, and a grove of oaks and maples, with both a sweet-water and a sulphur spring, is now available for picnic purposes, and, I may add, is well patronized.

Passing by both these finished and unfinished portions of the park, we proceed to "The Serpent," now lying directly before us. Upon a jutting tongue of level land, that reaches into, and one hundred feet above, the beautiful Brush Creek valley, rests that mysterious earth-work of an unknown people—a serpent, fourteen hundred feet in length, with closely coiled tail, gracefully curved body, and widely gaping jaws. Beautiful as it is in itself, our interest steadily increases as we look upon it, from the fact that it antedates all history. Since its discovery and description by Squier and Davis, in 1847, the spot has been often written of, and more theories have been broached concerning its age and origin than there are curves in its tortuous length. This has not been to the advancement of American archæology directly, but it has led to the purchase and preservation of the mound by the Peabody Museum of American Archæology and Ethnology, of Cambridge; and now it is not only available for all future students of ancient America, but its surroundings, some seventy acres, have been set apart as a public park, and so are of interest to the readers of GARDEN AND FOREST.

I have spoken of the unpark-like condition of the high plateau, through which the main drive passes. The present disturbed condition arises from the fact that every inch of the ground is being carefully explored for traces of the serpent builders, and the results so far go towards the establishment of the view that the people who erected the earth-work were not historic Indians—Cherokee or Shawnee, as has been asserted—but a race akin to, if not identical with, the ancient Mexicans. But I will not further trespass upon the work nor anticipate the conclusions of Professor Putnam, who is

conducting these explorations in a thorough and able manner.

The setting apart of a considerable tract in the midst of a rich farming district, as a public park, in connection with the preservation of this invaluable relic of the past, was a most happy thought; and additional educational interest centres in it from the fact that Professor Putnam has established here an arboretum on a limited scale, by having planted specimens of the many trees native to the region, thus returning it to the conditions obtaining previous to the advent of the white man.

As years roll by, this beautiful spot will undoubtedly become more and more attractive, and the wisdom of the establishment of the Serpent Mound Park will be universally acknowledged. Let us hope, therefore, that the efforts now being made to preserve other equally interesting traces of a forgotten people, in Ohio, may be likewise successful, and not one but several such parks be the boast of the people of this thrifty State.

Serpent Mound Park, Ohio. _____ Charles C. Abbott.

English Flower Gardens.

IT is pleasing to see the increasing love and extended cultivation of hardy flowers, but the improvement of English flower gardens by their use proceeds very slowly. In many places the flower garden is still sacrificed to bedding out and presents the same meagre assortment of plants, the natural consequence being that in summer English flower gardens have great similarity of aspect, with few features of real interest. Each season brings the same monotonous form, with perhaps a little variation of style.

Pattern gardening was and is the greatest enemy to both gardeners and gardens; to gardeners, because, owing to the lack of material that would readily lend itself to this, many present-day gardeners are under the idea that beautiful flower beds cannot be made with hardy flowers; to gardens, because, in all situations and on different soils, each of which is capable of supporting some distinct types of vegetation peculiar to itself, the same subjects have been used. Hence the ultimate outcome, formality and sameness. We do not meet with so many of the complicated carpet enormities as in former days, but there is still room for vast improvement. It is too much to expect owners of gardens to undertake the work, although there are a few exceptional cases where this has already been done. Nevertheless, there are plenty of people who think and admire, and, without a doubt, would appreciate a change which tended towards the improved embellishment of flower gardens by the use of an increased variety of hardy plants. Before this can be done a much wider knowledge of plant life will be needed. We want originality and the capacity to evolve new ideas. It is the lack of knowledge of the inexhaustible resources of Nature that is the root of the evil; and how can it be otherwise while young gardeners are trained under glass alone, and are scarcely brought into contact with hardy flowers, trees or shrubs?

A judicious and proper selection is of great importance. A few beautiful bedded-out gardens have been made, against which little reproach could be urged, but they have been carefully planted, and they have been beautified with a greater variety of summer garden plants. The mass of flower and gorgeous color has been toned down by graceful foliage and refreshing greenery. To one beautiful garden of this kind there are hundreds sacrificed to about half a dozen subjects, that were grown twenty years ago and are still grown now. During the present summer I was shown over a place which had the reputation of being fairly good, and after having walked around the flower garden and been asked to admire the usual scarlet, yellow and blue monotony, I found only one feature of real interest, and that in the kitchen garden mixed border. It was a large group, covering several square yards, of a very fine form of the white *Campanula Persicifolia*. The distant effect was very charming. The flower garden is the true home for all such flowers as this, and many more might be easily selected.

The beautiful garden of the future will be adorned with hardy flowers planted in open natural groups instead of the old dot-a-plant-everywhere system, that rendered the mixed border so unsatisfactory, and did not give a true idea of the capabilities of many of the subjects planted therein. An ideal English garden should have beautiful flowers for at least nine months out of twelve. We want lasting interest, a garden with vegetation that changes with the seasons, but is not defined by them. Week by week, month by month, some fresh charm should appear, some new picture unfold to view. The garden of hardy flowers is equal to this.—*The Garden*, London.

Foreign Correspondence.

London Letter.

THE Oleander (*Nerium Oleander*) is now among the glories of southern gardens, especially in Italy. The other day I strolled through one of the famous gardens on the banks of Lake Como, and in that paradise of flower and fruit nothing delighted me more than the large Oleanders, covered with blossoms as large and as double as Camellias. I had never before seen this plant in perfection, for it cuts a poor figure in English gardens. We cannot give it the roasting sun-heat and cloudless skies that seem so necessary to its perfect growth, but I believe that in the United States it would flourish as it does in Italy, since you could give it the summer-heat it wants, and its protection in winter, when grown in portable tubs, is not a great undertaking. Of some dozen distinct sorts seen in Italy the difference consists mainly in the color of the flowers. Besides the deep rose-pink, which is common everywhere, I saw a variety with pure white single flowers, one with flowers double white, a double deep red called Splendens, a double rose, a large single, copper-colored (*Cupreatum*), a pale yellow, double and single, and a very rich rose-purple named Professor Duchartre. Other unnamed varieties were quite as fine. On inquiry I found that the bushes received little or no attention. They were for the most part in large square tubs, and all looked as if they had been undisturbed for years. Each season a slight top-dressing of manure and soil was given, more to fill up the tubs than to benefit the plants, and all the attention given was frequent watering, the Oleander being a very thirsty plant. In some places the tubs are put under shelter in cold weather.

The Shrubby Mallow, as *Hibiscus Syriacus* is commonly called in English gardens, is one of the few hardy shrubs at present in bloom, and very attractive it is when in flourishing condition. To do well it must have a deep, moist soil, the richer the better, and if, in addition to this, it is sheltered and partially shaded, then it is a beautiful shrub in autumn. There are now a multitude of varieties in our gardens, most of them with very uncouth names, and many of French origin. There is, however, a great sameness in the majority of the sorts, the prevailing color being a kind of purplish rose, with crimson centre. In a large collection of sorts at Kew I singled out the following as the most distinct: Puniceus plenus, Rubro plenus, Albo-plenus, Cœruleus plenus, Ardens and Duc de Brabant. In Mr. Anthony Waterer's nursery at Knap Hill there is a fine display of bloom, two of the finest sorts being Totus albus, a pure white variety, very beautiful, and Cœleste, which is the nearest approach to a true blue Hibiscus that has been obtained. The flowers are large, single and of a rich purple-blue, quite a different tint from that of any other sort. The great value of the Syrian Hibiscus lies in its autumn flower, and that is why it is always planted in English gardens, whether the conditions are suitable for it or not.

Lemoine's Hybrid Montbrietas are now found to be indispensable autumn flowers, being so graceful in growth, so profuse in flower, and so bright and rich in color. The first hybrid which came to us a few years ago, under the name of *M. crocosmieflora*, was the result of intercrossing *M. Pottsii* (a Cape species, with wheat-ear-like spikes of small red and orange flowers), with the well-known old *Tritonia* (*Crocosma*) *aurea*, with large bright orange-red flowers. The hybrid combined the character of the parents in a remarkable way. Its flowers became larger than those of *M. Pottsii*, but quite as numerous, while the color was intermediate and more pleasing than that of either parent. It was, moreover, soon found to be much hardier than *T. aurea* and could be left out in the open border in winter like *M. Pottsii*. This original hybrid, *M. crocosmieflora*, has now become a popular garden plant with us; in fact, is quite common, and especially as a pot plant in green-houses. Its sheaf of waving flower stems in August

and September makes it very beautiful, and as it continues in bloom for weeks, its value is enhanced. M. Lemoine, the famous hybridist of Nancy, has raised other hybrid Montbrietias, one of which I saw the other day in Mr. Wilson's garden at Weybridge, under name of Gerbe d'Or. It is like the older *M. crocosmiaeflora*, except that the flowers are of a pure rich yellow, instead of orange-red, blotched with crimson. It is very beautiful, and though it has not come into general cultivation, it is certain to become popular, especially as a green-house plant.

Ivora Duffii.—Those who want a really fine stove plant for autumn flowering should become possessed of this evergreen shrub, introduced a few years ago from the South Sea Islands. In my opinion, it is the finest of all the *Ixoras*, for though it does not produce such a number of small flower clusters, its huge heads of bloom have an impressiveness which places it in advance of all others. A well grown plant is about four feet high, with large, deep green leaves, and it produces, at the extremity of each main shoot, an enormous cluster, often nine inches across, of deep scarlet-crimson flowers. It generally begins to flower early in August and lasts in bloom for several weeks. It is of simple culture under ordinary warm-stove treatment. It is grown to perfection at Kew in the Water Lily house, which is always moist and warm, and it has been the admiration of visitors for weeks past. It is a stock plant in nurseries and is known also by the name *T. macrothyrsa*.

London, September 20th.

W. Goldring.

New or Little Known Plants.

Rhododendron (Azalea) arborescens.

THIS beautiful Azalea was first made known to botanists by Pursh, in his "Flora of North America," published in 1816. He had found it in the mountains of Pennsylvania, and in Bartram's garden at Philadelphia, where John Bartram, who was, therefore, its real discoverer, had planted it many years before. Neither the elder Michaux, who traversed over and over that part of the country where this species is most common, nor Fraser, who had explored the Alleghany Mountains some years before Pursh visited that region, seems to have noticed it, although it is hardly possible that they would have overlooked so common a plant, which they, perhaps, confounded with *R. viscosum*.

It is stated in Nicholson's "Dictionary of Gardening" that *Rhododendron arborescens* was introduced into English gardens in 1818, but it has probably never been very well known in Europe, and was soon lost, perhaps, from gardens. Our figure upon page 401 is, at any rate, the first which has been published of this plant, which, through the agency of the Arnold Arboretum, has been distributed within the last five or six years among many of the principal American and foreign collections.

Rhododendron arborescens is a tall shrub, with slender branches, sometimes fifteen or twenty feet high, and obovate or oblong-obovate, slightly coriaceous leaves, ciliate on the margins, bright green and shining on the upper and pale on the lower surface. The flowers are white or tinged with rose, the long, slender tube of the corolla, and the conspicuous, narrow calyx-lobes somewhat glandular bristly. The brilliant scarlet stamens and pistil add to the beauty of the deliciously fragrant flowers, which are not viscid like those of its nearest American relative, the familiar Swamp Honeysuckle (*R. viscosum*). They are later than those of other Azaleas, not appearing until July, and are often obscured by the shoots of the year which precede them, a habit which lessens somewhat the value of this species as a showy garden plant. The leaves, in drying, exhale the perfume of newly mown grass—a character which has not been noticed in other Azaleas.

Rhododendron arborescens is a native of the mountain region from Pennsylvania to South Carolina and Tennessee, where it is frequently found in great abundance, especially among the foot-hills of the high mountains

of North Carolina, bordering and often overhanging the smaller streams and filling the woods in early summer with fragrance.

It is perfectly hardy in the Arboretum, where it receives no special treatment, and flowers freely every year.

Cultural Department.

Winter Apples.

THE Baldwin is the most satisfactory winter Apple, as well as the most popular variety in this vicinity, and yet in the southern part of this state it is regarded as a fall Apple, and esteemed only as such. I confess its record for keeping qualities is not as good here as it was once, but its size, beauty, flavor, and fine bearing qualities render it a general favorite notwithstanding.

The universally popular Rhode Island Greening is still a great favorite, but it does not grow as smooth generally as the Baldwin. Neither does the tree grow as well. Its reputation as a keeper is also on the wane; and this will apply to all of our Apples once famous for long keeping. It was not unusual years ago for farmers to have a generous supply of Apples in April and May, a thing now very rare indeed. The cause or causes contributing to this changed condition give rise to much speculation, but no conclusion that is generally accepted has yet been reached. Possibly new varieties may be developed in the future that will occupy the positions in this respect once held by our old-time favorites.

Smith's Cider is a very popular winter Apple in Pennsylvania and southern New Jersey. The Apple is of fair size; the trees bear young, and when grown are immensely productive. The fruit is of fine quality and keeps well. It promises to do well in this section of the state.

One of the best winter Apples I am acquainted with is Peck's Pleasant. High-flavored, productive, and a good keeper, it very well fills the place once occupied by the famous Newtown Pippin, a variety long since superseded by others better adapted to our locality.

Northern Spy is also a fine, high-flavored winter Apple, but the tree is rather tardy in bearing, and the fruit is very liable to grow imperfect, and rots to such an extent as to impair its value.

Fallwater is a large Apple, a young and abundant bearer; very popular in some portions of Pennsylvania, but of late I hear complaints that the trees fail early. The fruit is not of first-rate quality.

Ben Davis, a popular Apple in the West, gives good promise here of early productiveness. The fruit is fair, handsome, of good size, and keeps well, but the quality of the fruit is far below that of the varieties already named.

Winesap, a beautiful red Apple, of excellent quality, of medium size, has proved one of the best keepers.

Yellow Bellflower is also a fine-looking and good-keeping winter sort. It seems among winter Apples what the Orange is among autumn ones, the chief objection to it being its large core.

Wagener stands near the head of all the winter Apples I am acquainted with for quality; of medium size, with a tender, crisp, fine-grained flesh.

In southern New Jersey the Roman Stem is a great favorite, an Apple the farmers always keep for their own use. At the Mount Holly Fair two years ago there were about fifty plates of this Apple on exhibition, entered for the prize offered for the best plate, which shows how extensively it is grown there. I am not aware of its trial in this section.

For a sweet winter Apple which is wanted for baking, Talman Sweet is probably as good as any; but the winter sweet Apple of this region is the old-time Canfield, the standard winter Apple of our fathers and grandfathers, a very prolific sort, and one that will stand more rough handling than any other. A bruise on the Canfield will dry up; on any other it will rot. This Apple still holds its place in the affections of the farmer, though it is a poor Apple for dessert or cooking. Its great merit is for cider. Its old-time consort, the Harrison, once so popular, and the richest of all Apples, has failed so completely of late years that a tree of it is a great rarity. Its present status affords a fit answer to the question, Do varieties run out or degenerate? These two Apples were the foundation in years gone by of New Jersey's well-earned reputation for "Newark cider," vast quantities of these Apples being crushed together and distributed widely through the Newark market. There was a cider-mill on every third or fourth farm, but nearly all of them long ago fell into decay.

I have only given the names of leading Apples of established

Fig. 64.—*Rhododendron* (*Azalea*) *arborescens*.—See page 400

character and reputation. But besides these, and other less prominent ones, it is well to remember that every section has local varieties of real merit, especially adapted to their soils, and quite as profitable, if not of such fine quality, as any of the newer sorts. Many a good Apple has not been honored with

book registry nor described by an official pomologist. These old and valuable varieties should not be neglected and allowed to disappear. Every man who owns an orchard or an Apple tree should know how to graft and bud, and see that these choice old-time varieties are not forever lost. The old Pom-

pey, or Victuals-and-Drink Apple, was a great favorite here years ago, and would be as welcome to-day as ever, but I do not know of a tree in existence in this neighborhood, and it is doubtful if it could be had in any nursery. Other varieties are disappearing in the same way, and the loss seems all the more annoying when it is easy with a few buds or grafts from one of these old trees to put a new head on a young tree and preserve the old friends.

Montclair, N. J.

The Flower Garden.

NOTWITHSTANDING the sharp frosts last week our garden still shows many bright flowers. The Meteor variety of the Pot Marigold, from summer sowings, is in capital bloom, and likely to last for a month to come. Sweet Alyssum is as white and fragrant as ever; so, too, would be the Mignonette were it not for the very wet September just passed. The double white Feverfew is in good bloom a second time, and Tritomas will remain in full glow till Thanksgiving. Half the crop of buds of the handsome Japanese Anemones have not yet opened. What a pity this plant is not earlier and hardier. *Sedum Sieboldii* is perfectly hardy here, and its best bloom is in October. Sweet Violets are beginning to bloom, and the Eschscholtzia will display its golden flowers till snow comes. Maximilian's Sunflower is the finest species of its race at this time of year.

Hardy herbaceous perennials may now be transplanted. Tuberos-rooted species, like the Pæonias, Liatris and Monkshood, may be planted now as well as in the spring, and early spring flowers, like Moss Pink, Aubrietia, *Saponaria acymoides* and bulbous plants do better planted in fall than in spring. Columbines, in particular, do better when planted in the fall. But summer and fall blooming plants, like Veronicas, Phloxes, Helianthus, Japanese Irises, White Day Lily and the like, should be planted in spring, especially if these plants are to be divided, with the view of increasing the stock or reducing the size of the parent clump. Somewhat tender plants, like Japanese Anemones, Conoclinium, Acanthus and *Oenothera speciosa*, should never be disturbed in fall except to be removed to a cold-frame or other favorable quarters. If they have any chance at all of surviving the winter, it is as established roots, and not as newly-planted stock.

Japanese Iris (*Iris lævigata*) from Seed.

ALTHOUGH this Iris may now be imported direct from Japan in a multitude of beautiful varieties, the raising of new ones from seed may be made profitable as well as interesting. When left to their natural development they produce but little seed, and the varieties obtained from this are ordinarily no better and usually not as good as the originals, but when carefully hand-fertilized nearly every flower so treated will produce its pod of seed, and a large percentage of the flowers will be better and most of them quite as good as the parents. By actual count it has been found that of seedlings from hand-fertilized flowers, forty per cent. were varieties worth preserving, while of plants from seed produced naturally but six per cent. were good. It is desirable to have some varieties to flower earlier in the season, and this may be accomplished by a careful selection of seed from those that first come into bloom. Already we have plants which begin to flower in the latter part of June, and we still had fresh flowers on the 10th of August. Few garden flowers can boast of a much longer period of bloom than this.

That the raising of seedlings is not only interesting to the amateur, but may be made profitable to the nurseryman, is quite evident from the quantity of seed produced, which will average, from well fertilized flowers, about fifty in each pod, and when properly treated the young plants will be large enough to flower the second year, and a large stock may be secured in this way with much less labor than it can be by division. The process of hand-fertilization is quite simple after one has carefully studied the flower and located the essential organs. Upon examination, the Iris flower, in its normal form, will be found to be composed of nine distinct pieces or divisions, arranged in rows of three divisions each, one within the other. The two outer rows make up the six divisions of the perianth, the three outer are spreading or drooping and the three inner are smaller and stand erect. Inside of these again are three more divisions resembling somewhat the petals in form, but as close examination shows in reality the styles, with the stigmas near the apex in the form of a thin lip, the surface of which is covered with minute hairs. By pull-

ing back the petal-like tips of these styles the lip-like stigmas will be readily seen. Lying close beneath the styles, but connected at the base by the short and stout filaments with the tube of the perianth, will be found the anthers, which are long, lance-shaped organs, with the pollen contained in narrow cells along their margins. Nature, in providing for cross-fertilization, has so arranged the flower that the pollen is ready for use and gone fully a day before the stigmas are in proper condition to receive it; in fact, the pollen is ready for use before the petals begin to unfold, and it is a wise plan for the operator, after deciding what pollen he wishes to use, to take the flowers just as soon as they begin to open and cut out the anthers with a sharp pointed pair of scissors or small penknife, lay them away in folded papers or envelopes, marked

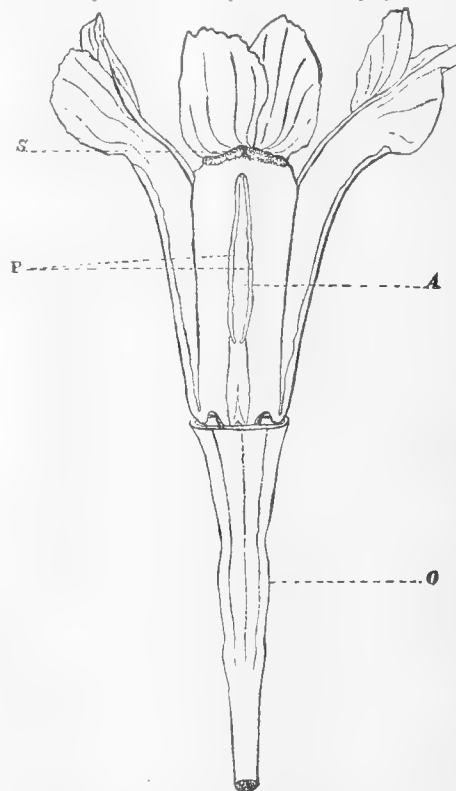

Fig. 65.—Flower of *Iris lævigata*, with the perianth removed. A, anther. P, pollen cells. O, ovary. S, stigma.

with the name of the variety from which they were taken, and keep them for future use; the pollen can be kept in perfect condition in this way for a week at least, and an abundance of pollen may thus be had when the stigmas are ready to receive it. This is an important precaution, for a very small native bee (a species of *Halictus*) is on hand as soon as the flower shows the smallest opening, and will have the anthers well cleaned of pollen by the time the flower is fully expanded. It would look as if the flower was made to be fertilized by the bumble-bee or some similar insect, but in this country, at least, the flowers are seldom visited by the larger bees, hence the scarcity of seed

when the plant is left to itself. When the flower first opens, the stigma will be found closely folded back against the style; but by the second day the upper edge will have been detached, and falling downward, the upper surface will be exposed and is now ready to receive the pollen. A small camel's-hair brush will be found the most convenient instrument with which to apply the pollen, which is done by simply taking off a quantity with the tip of the brush and lightly dusting the upper surface of the stigma.

The figure represents a flower with the perianth cut away, showing the three styles, one of the stigmas (S) and one of the anthers (A).

The good effects of this fertilization will be noticeable very early, for not only is it apparent in the flower when produced, but the pods are usually much finer and larger than when accidentally fertilized. The seeds germinate quite freely if planted, as soon as ripe, in good soil and carefully watered. For soil in which to plant the seeds I prefer well decayed leaf-mould in shallow boxes, from which the young plants are transplanted to the open ground the following spring.

Arthur H. Fewkes.

Chrysanthemums.

WE grow these largely for cut flowers and for out-door decoration. They are raised from cuttings rooted in the green-house in spring and planted out in May, in well manured ground, in rows three feet apart by two and one-half feet apart in the row. In summer they are cultivated, watered now and then in very dry weather, and tied up with one stake to each plant. About the end of August or in September we select and pot the plants most desirable for furnishing good flowers and late ones in the green-house. Our largest supply

of flowers comes from out-door plants, but if wet, frosty or windy weather renders the out-door flowers unfit to pick, we have a supply in the green-house; also when severe frost destroys the out-door crop, as it usually does between the 20th and last of November, late green-house plants are then most welcome.

About the end of September or first of October we empty some beds—warm, sunny, sheltered beds against the south side of the house—of their tender summer occupants and fill them with Chrysanthemums, lifting and planting them with as good balls of earth to the roots as can be had and crowding the plants pretty closely against each other so as to form a solid bank. The Chrysanthemums not only live and blossom as well as if they had not been transplanted, but they lose very few leaves. As planting proceeds they are well watered, and they are afterwards kept well watered both at the root and overhead.

In another warm, sheltered place we set out, about the first of October, a large solid bank of Chrysanthemums containing several hundred plants for cut flowers. A light wooden framework is erected over this bank, and in the event of wet or frosty weather, calico cloth is spread over this frame. Here we can have fine flowers from the end of October till the first of December.

Raising Chrysanthemums from seed is very pleasant work. During the last five years we have raised hundreds in this way and nearly all have been beautiful. The majority have single flowers, still a large number have semi-double or double flowers, and of many shades of white, yellow and red. But of all these hundreds of seedlings only three have been worth perpetuating. The amount of rubbish annually distributed among new Chrysanthemums is simply appalling. Of sixty-two new kinds we bought last year we have thrown fifty away, as being not only poorer than old varieties of the same types and colors, but not worth growing. We greatly feel the need of some centrally situated, competent and responsible body of horticulturists to whom new Chrysanthemums and other flowers could be submitted for their opinion; such a body as the Floral Committee of the Royal Horticultural Society of London. A first-class certificate from such a body would mean something. In fact, even here in America, horticulturists regard a first-class certificate by the Royal Horticultural Society as the highest award a plant can have, and we buy such a plant with full confidence that we are getting something distinct from anything else in its way and also something well worth growing.

Chrysanthemum seeds germinate in seven to nine days and

the plants grow readily. Sown in the house in March, the plants will be big enough to set out in May, and they will attain a large size during summer. They will show flower buds in September, and all will bloom in October or November of the same year. We have now 150 plants in one bed which have been raised from seeds sown last spring. They are larger than the named varieties which have been raised from cuttings; all are now full of buds, and in form and foliage they are distinct from one another.

The Cultivation of Phalænopsis.

IT would be a great mistake to class all the Phalænopsis with the easy-growing Orchids, as there are several which I have never yet seen in a luxuriant condition. Nevertheless, some of the species are amongst the finest Orchids known. They all flower freely, and continue a long time in perfection. I never found any difficulty in cultivating *P. amabilis*, *P. amethystina*, *P. Esmeralda*, *P. grandiflora*, *P. intermedia*, *P. leucorrhoda*, *P. rosea*, *P. Sandriana*, *P. Schilleriana*, *P. Stuartiana* or *P. violacea*. Of *P. Schilleriana* I have many leaves made this season which measure from fourteen to eighteen inches long and from three and a half to four and a half inches wide, and I am justified in expecting some very strong spikes of flowers.

The species of Phalænopsis are best grown in baskets, as a more equal supply of moisture can thus be supplied to the roots. I always re-moss them in April or May, and re-basket any that require it. Every precaution is taken with the heart of the plant to have it leaning over the edge of the basket, so as to prevent any drip from entering, as decay is pretty sure to result. When the plants are re-mossed all decayed matter should be removed, and clean potsherds, with large pieces of charcoal, should be returned. A large piece of charcoal, so placed as to protrude through the moss, is beneficial. The roots will cling to it tightly, showing their relish for it.

Phalænopsis cannot endure a low, narrow house. They must be close to the glass; but all other conditions being provided for, the more spacious the apartment, the better they will thrive. I take my largest specimens and hang them in the south end, where they will get the benefit of the light and warmth from the sun. They get a syringing underneath the baskets every bright morning in order to thoroughly moisten the roots, and they need enough water to keep the sphagnum moist, but not saturated. Syringing the leaves is a great mistake, as it tends to make them soft, so that they lack that

leathery appearance which gives promise of the strongest bloom. As a rule, the plants are over-watered at the root, while too little moisture is given in the air. The flower-spikes should always be supported in some way, for if allowed to sway to and fro they will probably break many roots and loosen the plants.

I have found water charged with fertilizing ingredients, such as ammonia, salt, guano or phosphates, very beneficial when applied a few weeks after the baskets have been re-mossed. Every care should be taken in ventilating, as *Phalænopsis* will not endure chilly air. Fresh air should be admitted by the ground ventilators, especially in windy weather.

Shading should be carefully attended to, as the burning rays of the sun would soon destroy them when the leaves are young and unaccustomed to its heat. They should always be kept perfectly free from insects, and if thrips appear a slight fumigation with tobacco will be needed. The night temperature of the house, from the 1st of November until the 1st of May, should be 60°; during May and October it may be 65°, and during the summer it should be kept at about 70°. The day temperature should range from five to ten degrees higher, according to the force of the sun.

Staatsburg-on-the-Hudson, N. Y.

A Few Choice Ferns.

WITHIN the last few years a large number of beautiful Ferns have been introduced, many of them useful for cutting, and a few unexcelled for basket culture. The cultivation of Ferns is becoming more and more an important branch of horticulture, and a few commercial establishments have already confined themselves almost entirely to these plants. The old and justly popular kinds will always take the lead for general trade purposes; for finer work, and especially for conservatory decoration, the newer kinds will always be sought for. One of the latest introductions, and the best in its class, is *Nephrodium rufescens tripinnatifida*, a large fern with fronds about four feet long, arching, wavy in outline, the pinnæ being very irregularly divided, light green, and covered on both sides with a reddish chaff. The stipes are reddish-brown and covered with a woolly coat of the same color, and the general appearance of the fronds gives one the impression of ostrich plumes. This plant is suitable for baskets, and makes a magnificent pot-fern; and for cutting purposes, where large fronds are needed, it is excellent. It thrives in a warm green-house, growing rapidly in rich, well drained soil, and requires an abundance of water. It is troubled at times with a soft scale, which may be prevented by constant syringing. It increases freely by the adventitious buds on its numerous stolons, which may be taken off as soon as they are able to take care of themselves.

Davallia tenuifolia Veitchii is an elegant fern and admirably adapted for basket culture. The fronds spring thickly from a creeping, wiry rhizome, and are about eighteen inches high, arching, with the pinnæ very finely divided, giving to the plant an airiness quite unrivaled. In color the fronds are pale green, while the stipes have a reddish tinge. It grows freely in an intermediate temperature, in a light compost composed mostly of peat. It should never be allowed to become dry; it is easily propagated by division of rhizome or by spores.

Grynogramma schizophylla belongs to the silver Ferns, and is vasiform in habit, with very finely divided, drooping fronds. It is one of the most graceful of the whole genus. It is recommended for basket-work, but does best with us in pots. This may be owing to the damp shelf on which the pots stand. The fronds are proliferous, and the young plants may be taken off, pegged in pots of sand and watered lightly until root action is well advanced. If these young plants are not needed, the beauty of the plant is much enhanced by leaving them on. The variety *Gloriosa* is much more vigorous than the last named, the fronds are longer, broader, but not so finely divided. Both kinds delight in abundance of heat and water, but if the foliage is wet too much the farinose powder will soon be washed off. A large proportion of loam in the soil will be found beneficial.

Among the new Maiden-hair Ferns, *Adiantum Williamsi* is probably the best. It is a strong-growing kind, with fronds about two feet long, which while young are covered with a yellow dust. It grows freely in an intermediate temperature, and will very quickly grow into large specimens. The mature fronds are good for cutting. A strong soil will be found best, especially when permanent specimens are required, and liberal applications of manure water are beneficial.

Adiantum Victoriae is a valuable addition to the dwarf-growing section. The fronds are about nine inches in height,

with few pinnæ, and the pinnules are large, with finely serrated edges. The general appearance of the plant is that of a dwarf *A. Farleyense*. It should be noted that to keep this Fern in good health it should be often broken up. The fronds grow so thickly together that large specimens are apt to rot at the centre.

Adiantum Pecottii is a charming little plant, about six inches high, much in the way of *A. bellum*, and, like this fine species, will be found very useful for general decorative work.

Among the many varieties of *Adiantum cuneatum* that named *Grandiceps* is one of the best. In this Fern the fronds are terminated by a tassel-like appendage caused by the fasciation of the terminal pinnæ. It is a splendid kind for baskets, and young plants in pots will be found superior to the species. It may be raised and will come true from spores.

Adiantum Weigandii, of American origin, is a handsome, robust species, which can be grown both in a warm and a cool temperature, and will prove an excellent kind where heavy foliage is needed.

Nephrodium Rodigasianum.—This is a very elegant Fern of vasiform habit, with broad, arching fronds, two to three feet long, of dark green color. The pinnæ are long, deeply and irregularly cut, with somewhat wavy edges. It has decided preference for a cool house, and requires liberal treatment in respect to soil and water. It grows rapidly, and is easily raised from spores. Unfortunately, the fronds are too brittle to be of any use for cutting.

F. Goldring.

Kenwood, N. Y.

Removing Raspberry Canes.—It is still debated whether this should be done soon after the fruit is gathered or left till later in the season. I have for years cut them as soon as convenient, after the berries are picked. My reasons for an early cutting of the old canes are that, having served their purpose, they are of no further use, and if allowed to ripen and mature till a natural death follows, they are a useless drain upon the soil and the vitality of the plant. If removed, the young canes receive all the nourishment furnished by the roots, and should be better developed and matured as a consequence. It is also easier to cut off the canes while still green than when dry and dead. Hand-shears are preferable to a knife, avoiding the pull, which sometimes lifts the whole plant, when the canes are hard and dry.

The opponents of early removal claim that these old canes are an aid to the maturity and development of the young canes; that it is Nature's way, and therefore right. It is also claimed that if left till spring they afford needed protection during the winter to the young canes. There is a show of reason in the protection theory, but as the injury is very apt to occur in early spring, after the old canes are removed, the benefit becomes less apparent, and is more than counterbalanced by the draught on the plant in the process of ripening. The above remarks will apply also to Blackberries, the worst of all the berry canes to handle.

Geraniums, Crane's-Bills.—These include some useful border and rock-garden plants. All the kinds in cultivation, with one or two exceptions, are hardy in this country. The alpine species will require good drainage, but the others will grow almost anywhere. Geraniums have a long flowering season, and bloom more or less from early May until frost. This is the case, particularly, with *G. sanguineum*. Plants are easily raised from seeds or root-cuttings, and they hybridize freely. The best alpine kinds are *G. argentum*, with silvery foliage, and pinkish flowers with darker veins; *G. cinereum*, resembling the preceding, except in having greener foliage and darker flowers; *G. macrorhizon*, with purple flowers and a woody root-stock; *G. sanguineum*, a trailing species, with pretty blood-red flowers and blooming from spring till fall. This plant always looks neat and is very easy to grow. Its variety, *Lancastrienne*, is equally handsome, with pink flowers and darker veins.

Amongst the border Geraniums are some very handsome ones. *G. collinum*, purple; *G. Ibericum*, blue; *G. Ibericum palatypetalum*, violet and veined; *G. phœum*, very dark blue, with a white spot at the base of each petal; and *G. pratense*, notably the double blue and single white forms—all bloom in spring, and make a considerable display while they last, and again in the fall, though not so abundantly. *G. Endressii*, rose, one of the best and very useful for cutting; and *G. Armentium*, one of the noblest of all, growing sometimes four feet high, with dark crimson flowers, bloom all the season. The common *Geranium maculatum* grows in swamps, and on dry banks as well, though less luxuriantly. T. D. Hatfield.

Wellesley, Mass.

The Forest.

Forestry in California.—IV.

The effect of forests on rainfall is not as yet sufficiently determined. The total rainfall of the world would, perhaps, be no less were forests not in existence, but it seems to me that an examination of the subject must lead us to conclude that the distribution of the rainfall is affected by them.

Forests continually operate to equalize temperature. The capacity doubles with a mean increase of 23.4 between the freezing point and 100 degrees fahr. Thus in the spring and summer the cooling effects of forests on temperature must diminish the water-holding power of the air. In walking or riding, every one must have noticed the difference in heat between a bare verdureless spot and the shade of trees. This difference is observable even in walking from a dusty road to a grass-covered lawn, thus indicating that the variations of temperature do not depend upon the shade alone. Consequently a current of air saturated for a sandy waste would of necessity, in passing through a forest, part with some of its humidity, owing to the lower temperature. It is for this reason that we see clouds gathered about mountains, when the valleys are under a clear sky.

I have often sat upon the sandy coast of Egypt and watched the sea breeze, full of clouds seaward, clear itself on reaching the coast: all the atmosphere over the water fleeced with clouds, while to landward all was sunshine. Our own coast breezes show the same phenomena; the foggy winds of San Francisco soon become the clear breezes of Sacramento, because the temperature of the latter will not permit the moisture to remain condensed.

I have records of many observations made in our Central States showing that the summer rains are more frequent in wooded districts, and usually follow timber belts and water courses.

There are also a number of observations on record showing that the electrical effect of trees may play an important part in rainfall. Trees attract electrical discharges, as is known in the case of lightning, and coupling this fact with an experiment made with a collander so fine that water merely oozed through, from which, on the application of an electrical current, the water poured out of the small apertures; we must conclude that the effect of trees on rainfall through electricity may be considerable.

Whatever the effects of forests may be on the amount of rainfall, it is beyond doubt that their influence on its delivery is of the first importance.

Trees offer innumerable obstacles to the running off of rain. Their foliage obstructs the force of the rainfall; when this reaches the ground it is impeded by the fallen twigs, leaves and the labyrinth of roots and the humus; by the latter it is rapidly absorbed and held as in a sponge. The roots, at least when decayed, form channels into the lower soil. These impediments cause the water to flow very slowly, and prevent it from gulying out the land and forming accumulative channels. Thus the rain has time to sink into the earth and to replenish the subterranean reservoirs of the springs. The waters percolating out of forests never carry earth in them, as is the case on lands denuded of vegetation. The rate of delivery of a given rainfall from a wooded water-shed is much slower and is much longer continued than from a bare one. The importance of this will be understood when we recall the French experiments at St. Phalaz. At that place there are two water-sheds of nearly equal area and inclination; the one wooded, the other not. From the first proceeds a nearly perennial stream, from the other a dry gully. The period of delivery of flood waters in the first is five days, while in the second the period is only six hours, and it is but fair to presume from the stream in the wooded one that it is a delivery of water that months before fell in rain, which amount of water falling upon the other water-shed augmented its flood.

The first of these water-sheds causes no destruction to the roads nor extensive erosions of the banks of the stream, while the floods from the other wash away the bridges, destroy the roads and roll gravel and boulders into the valley.

Supposing ten billion gallons of water to fall within a given time upon each of these water-sheds. From the first the delivery will extend over a period of five days, or 120 hours, some of it being permanently retained to supply the springs and stream; while from the other the ten billion gallons will flow off in six hours with scarcely any absorption into the soil itself, consequently the delivery of water during a given moment during the flood must be twenty times greater in the

denuded ravine. Every second of prolongation of water delivery diminishes its height, force and danger.

It is in denuded and mountainous water-sheds that torrents are formed. The undetained waters rapidly form channels and erode the land, carrying earth, sand, gravel and boulders in their flow. As the inclination of water-sheds diminishes, the debris is dropped, first the boulders, then the gravel, then the sand, and last the earth and clay.

Standing upon the dykes of the Talfer torrent at Botzen, in the Austrian Alps, I observed the dry bed of the stream to be on a level with the roofs of the three-story houses at Schländers, Kortsch and Lais; the church steeples are lower than the bed of the Gadribach. The water-shed of the Durance, in France, was formerly wooded, as we know by the records of the lumbering corporations that operated upon it. For years it has been denuded, and the river now varies from a vast bed of pebbles and sand to a furious torrent. It has covered more than two hundred thousand (200,000) acres of one of the formerly most fertile valleys of Provence.

In Southern California the same causes are already producing the same results. Fires have been set and are being set by sheep men, which burn the brush and forest and prevent new growth. New torrents in unexpected places have formed, and the old channels, such as the Tejunga, Santa Clara, San Gabriel, etc., are more subject to floods than formerly with the same rainfall.

When we contemplate what has happened in other countries, we cannot but perceive that the mining debris of our central valleys is nothing to what must be expected from torrential action from such a chain of mountains as the Sierra Nevada, with its easily disintegrated formation, should it be denuded of vegetation, and the snows be unprotected and the rains undetained.

The principal sources of danger to be anticipated in this direction are the fires which annually do more and more damage, and the over-pasturage of the mountains, which packs the earth, destroys the humus, and, through the hunger of the half-starved sheep, causes the destruction of the natural reproductive power of the forests by reason of the eating by these animals of the young trees. As has been said, it cannot be doubted that the sheep-men in our mountains do every year a hundred times more damage to the lumber, to the streams and springs, and to the retentive power of the water-sheds than the scanty mountain pastures are worth. Sheep-pasturage should be regulated as it is in Europe and confined to particular forest tracts with such limitations as the condition of the forests requires. In this way the mountain pastures could carry more sheep than now, for under the present system both forests and pastures are being destroyed.

The secondary effect of denudation of mountains and the consequent formation of torrents is the diminution of springs and streams in their summer flow. The rains rushing off rapidly have no time to sink into the subterranean reservoirs, and consequently the springs must fail.

Col. H. H. Markham, a Congressman from Southern California, who introduced the Forestry Bill prepared by the California Board into the last Congress, in a letter to me, says:

"I was born, raised, and have always lived in a timbered country, and have watched the effect of timber upon natural water courses, and I am thereby fortified in my belief that your position is correct. My brother owns a farm in Sheboygan County, Wisconsin, a county heavily timbered. He built a single mill on the creek passing through his farm and ran it by water-power, but as the land surrounding him became shorn of its timber and cultivated, the stream diminished and soon became dry. He sold and purchased another tract in the next county north, and when I first saw it, in 1861, there was a stream running through it containing sufficient water to allow him and others to float double length railroad ties by the hundreds down it to the market. The surrounding country was rapidly cleared, and within six years the stream became dry, with no water, except in rainy seasons."

California uses much water in irrigation, and in the south pays high for the fluid for domestic use. The value of water here, already considerable, must increase with the population. Consequently it is of vital importance to preserve at least the present capacity of the mountain water-sheds, to retard the melting snow and the delivery of rainfall, so that torrents shall not form to destroy the valley lands, and the springs and streams be maintained.

The State of California has no practical forest-system, neither has the Federal Government. The forest lands of the state in private hands are beyond the control of the State Board of Forestry, and the State School-lands and Government-lands in

forests are common to all for entry, pasturage, etc. No forest officer has any control over them, except to arrest for setting fires in the woods, and even in this the circumstances are so adverse to fixing the responsibility for these fires, that, with the utmost efforts, few arrests can be made, and fewer convictions had.

The state sells its land without any reference to the timber upon it. Practically all the school-lands in timber in California are mountainous, and are unsuited to agriculture. Where timber-land is bought in this state the timber is all that it is bought for, and after this is cut it is usually abandoned for taxes, if, happily, all the school payments due the state have been made. On the school-timber sections, in many cases, wood and lumber has hitherto been taken without so much as a by-your-leave from any one.

This Board is, as far as we know, the first official body to ask for an accounting for the school from the wealthy firms who have taken such timber. We have a special agent and assistants now in the field collecting evidence in these and other forestry cases by affidavits. The amount of money involved is very considerable, and belongs to the schools. We are obliged to proceed through the Attorney-General of the state, and hope to secure his co-operation in our work.

The United States land-system only allows a man to acquire 160 acres of forest-land. This is far too little to warrant the building of a modern saw-mill, consequently lumbermen have either cut timber without title to the lands, or used "dummies" to obtain by fraud and perjury what they required. There are doubtless cases in which lumbermen have good titles.

The government has for some time had special agents on the coast to secure evidence against illegal cutters of timber. These officers now have a great number of cases on hand, for the practice of robbing the government lands has been general. One case, that of the United States *vs.* The Sierra Lumber Company, for \$2,000,000 worth of stolen timber, is now on trial, and another involving 600 fraudulent land entries in Mendocino County, in the interest of one foreign firm, is before the courts. These are the leading cases of each kind. These lands are almost all worthless except for the timber on them.

At present there is no management over pasturage here. Robbed and burned everywhere. This is our forest-land system. A few special agents report, a prosecution or two is started, but the government attorneys, from some cause, bring few to trial. Fraud and illegality is at a premium in the lumber industry, and the honest man can hardly tell what to do in it to live and follow the law. Such a system, with such results, must be bad. A vast property is being squandered, the country endangered, and the citizens tempted to violate the law.

What the timbermen want is the timber, not the land. What the people in general need is that the water-holding power of the mountains shall be preserved. A sensible forest-system can sell the timber, while preserving the reproductive power of the forests and the forest itself as to its water-holding capacity, just as is now done in South Australia, India and in Europe. The forest-land ought not to be sold; not another foot of it should be sold by the state or by the federal government.

Abbot Kinney.

Correspondence.

Hardy Trees.

THE introduction of ornamental trees from Japan during the last ten or fifteen years has claimed so much attention, that it is a matter of interest to determine what limitations of growth are imposed by the often severe climate of the northern United States and Canada. In the vicinity of Montreal the species specially worthy of note at this time are *Ginkgo biloba*, *Circidiphyllum Japonicum*, *Actinidia polygama* and *Paulownia imperialis*. With the exception of *Actinidia*, these are all growing in the grounds of McGill University. The situation is directly at the foot of the Mount Royal slope, and opens out on the east, but is well sheltered on the west. The adjacent buildings afford a somewhat additional shelter on the south, while the surrounding trees seem to break the force of the wind from all quarters.

In October, 1881, a *Ginkgo* was brought from Rochester. For a few years the growth was slow, but it has gained steadily. After eight summers and seven winters the tree now shows an increased strength, which promises well for its future growth, and gives assurance of its probable hardiness. Although the rate of growth has probably been much slower than in its native country, the tree has attained a height of fourteen feet six inches, with a girth of seven inches

at one foot from the ground. During the past summer the main shoot made a growth of four feet four inches—much in excess of the growth of former years.

A second specimen, received from Mr. Charles Gibb, from a locality about forty miles south-east from Montreal, was set in May, 1884, and has now attained a height of seven feet six inches and a circumference of 3.25 inches at one foot from the ground. In each of these cases there has been no winter-killing, and the trees appear to be well established.

The *Circidiphyllum* was planted in May, 1882. In seven seasons of growth it has reached a height of twelve feet four inches, and a girth of seven and a half inches at one foot from the ground. In this case, also, there has been no winter-killing, and the tree appears well established and hardy.

The *Paulownia* was planted in October, 1881. The stems have been killed to the ground each year, but the growth of each season has proved larger than that of the preceding, and this year reached a height of ten feet. The roots, which are quite hardy, appear to be gaining strength each year, and the plant is quite as well established as the one growing in the Botanic Garden at Cambridge.

The *Actinidia* referred to was imported from Amherst, Massachusetts, three years ago, and planted by Mr. Gibb at Abbot'sford. The situation is at the foot of Tamaska Mountain, having a south-eastern aspect. The soil is an open gravel. A slow growth the first year has been followed by a luxuriant growth for the last two seasons, and there is every reason to consider the plant quite hardy.

These facts may derive additional interest from the following considerations:

Montreal is situated in north latitude 45° 30' 17", and as shown by the records of the College Observatory, based upon observations for the last thirteen years, the mean annual temperature is 41.72° F.; relative humidity, 74.3; rainfall, 26.90 inches; and snowfall, 125.3 inches. The lowest temperature recorded since 1880 was -26° F., which occurred in the years 1882 and 1887. It will thus be noted that all of the plants under consideration have, once at least, been brought under the influence of a temperature many degrees below that to which they are subjected in their native country.

Paulownia is a species essentially belonging to central and southern Japan, and therefore to a much lower latitude than this. *Ginkgo* is common throughout the empire with the exception of *Yeso*, where it is rarely seen in the southern extremity. It may be regarded as not extending above the forty-first parallel. *Circidiphyllum* is abundant through northern *Yeddo*, and is everywhere found in the woods among the foot-hills of *Yeso*. *Actinidia* also abounds in the same region, so that both of these species extend northward to the latitude of Montreal. Yet it must be borne in mind that the insular climate of Japan, even so far north as 45°, is much less severe and far more equable than here, while the snowfall is practically the same—the meteorological records for Sapporo, latitude 43° 3' 57" N., for the last six years, giving a mean of 156 inches.

Montreal, October 1st, 1888.

D. P. Penhallow.

Ostrowskya magnifica.

To the Editor of GARDEN AND FOREST:

Sir.—Allow me to correct, for the sake of history, a slight error in one of your late London Letters. This plant flowered for the first time in Europe in 1887, in my little garden at Baden-Baden, from whence the big plants have passed into the hands of Messrs. Veitch & Sons. It is as hardy as any weed, and, though pushing early, the young shoots are not harmed by frost; it is not particular as to soil, but prefers sandy loam, which in any case must be deeply worked, as the root, when reaching full size, descends to a depth of two feet in the ground. Great care must be taken in handling the roots, because they are exceedingly brittle and a rough touch may cause them to decay.

Baden-Baden.

Max Leichtlin.

To the Editor of GARDEN AND FOREST:

Sir.—Is there any better way to rid squash vines of those ugly white worms than to hunt for them and destroy them? My gardener says that if the seeds were planted later the worms would not trouble them. But, in that case, we run the risk of the frost, which caught my vines this year before the squashes were ripe. What shall I do—take the chances of frost, or fight?

Concord, Mass.

A. W.

[Plant when the ground is warm enough, say the middle of May, and cover the hills with boxes over which mosquito netting has been tacked. Leave the boxes on

until the leaves begin to crowd the netting, then remove them and place among the plants corn cobs dipped in coal tar. Do not allow the tar to touch the plants. Redip the cobs once a month until the middle of September. This treatment will ward off all foes except, perhaps, the Squash bug (*Anasa tristis*), and this is rarely so abundant as to work much harm.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—I am inclosing a portion of my piazza for a conservatory. The sashes are so arranged that they can be taken away in the spring. The exposure of this conservatory will be south-east and one of the house chimneys passes up through it. I write to inquire about the best method of heating in an inexpensive manner. Is there any small stove made that I can use which will be fairly free from the escape of gas, and with some provision for the evaporation of water, that the heat may not be too dry? . . . P. B. J.

New York, July 26th, 1888.

[It is not practicable to satisfactorily heat a conservatory with a stove or without hot water or steam pipes. Hitchings & Co., of this city, make a base-burner boiler which is efficient for small work and economical. It heats hot water pipes, and the plan of putting them in should be entrusted to the maker of the boiler or some capable engineer.

There is also a heater much used for warming brooders in Hammonton, N. J., where many young chickens are raised in the winter. It is the plan there to introduce fresh air warmed by passing over pipes of hot water. The apparatus is simple and inexpensive, and would, no doubt, answer the purpose of our correspondent. It is manufactured by Bramhall, Deane & Co., of this city.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—I was at Charlestown, New Hampshire, during the summer, and saw growing Alfalfa, forty pounds of the seed of which had been sent from Colorado and planted there. It had been cut once, and was ready to cut again, and would probably yield five tons or more to the acre during the season. As is well known, it is a very valuable crop for cattle, sheep and hogs in California, and planted on rich, damp land gives large returns. I am told it could be used to great advantage for ensilage, and would like to inquire through your journal why it is not generally grown in the Middle States and parts of New England?

Boston, Mass.

Franklin Hunt.

[Crops of Alfalfa larger than that reported by our correspondent are not rare in the Middle and New England States. At the New York Experiment Station it starts well, does not winter kill, gives two, and even three good crops a year, thrives on the heaviest soil and endures drought admirably. The New Jersey Station reports that Alfalfa can be cut three or four times a year for five or six years in succession, yielding as heavy a crop per acre as fodder Corn. A gentleman near Boston writes that he cannot dispense with it as a soiling crop. And yet, for some reason, the use of Lucerne has never become general, although it was successfully cultivated nearly 100 years ago in the Middle States. The fact is that it very often fails. At a farmers' meeting in Schenectady last spring, Colonel F. D. Curtis replied to some one who marveled that this plant was so generally neglected by saying, that once in about twenty years agricultural writers unite to commend Lucerne and quote many instances of success. But the fact that the plant soon drops out of notice again is proof that it lacks some quality essential in a first-class forage plant. Secretary Guld, of Connecticut, says that repeated trials have been made with Lucerne in that state, but they have all resulted in failure. Still, the occasional successes are so striking that the plant is worth trying in a small way on every farm. Some authorities hold that an open, porous subsoil is essential to the best growth of this plant, which roots very deeply. The complaint is often made that a good "catch" of seed cannot be secured. But this could be remedied by care in preparing a well pulverized but

compact seed-bed. It is often sown broadcast, but the young plants are small and feeble, and easily smothered by weeds. The seed should, therefore, be sown in drills that are far enough apart to admit cultivation between the rows until the plants are established. Probably a lack of cultivation and sowing the seed on a soil that rests upon an impervious hard pan, are the most frequent causes of failure. But, after all, it must be admitted that agricultural authorities are not prepared to speak with positiveness of the conditions which are essential to success with this crop.—Ed.]

Recent Plant Portraits.

Eucalyptus calophylla, *Revue Horticole*, September 16th; the Australian Red Gum, which Monsieur André recommends for general cultivation in southern Europe, for its ornamental qualities.

Cattleya labiata, var. magnifica, *Gartenflora*, September 15th.

Quesnelia Wittmackiana, *Gartenflora*, September 15th.

Pentstemon rotundifolius, *Gardeners' Chronicle*, September 8th.

Pinus Pyrenaica (vera), *Gardeners' Chronicle*, September 8th.

Arauja graveolens, *Gardeners' Chronicle*, September 8th; a beautiful, white-flowered stove-climber, closely allied to and requiring the same cultivation as Stephanotis.

Rhododendron Collettianum, *Gardeners' Chronicle*, September 15th; a dwarf species from the Kuram Valley of Afghanistan.

Convolvulus tenuissimus, *Gardeners' Chronicle*, September 15th.

Chironia peduncularis, *Gardeners' Chronicle*, September 22d.

Pentapera sicula, *Gardeners' Chronicle*, September 22d.

Passiflora Miersii, *Gardeners' Chronicle*, September 29th.

Ursinia pulchra, *Gardeners' Chronicle*, September 29th.

Ruapellia grata, *Gardeners' Chronicle*, September 29th.

Botanical Magazine, October, *Howea Belmoreana*, t. 7018; this, the *Kentia Belmoreana* of many gardens, is a small and graceful cool-house Palm from Lord Howe's Island, off the eastern coast of Australia.

Rhododendron Collettianum, t. 7019; an alpine white-flowered species, from the high Afghan mountains, introduced by Dr. Aitchison; of considerable horticultural value.

Iris Alberti, t. 7020; a handsome species, with large, bright lilac flowers, lately discovered by the Russian botanists in the mountains of Turkestan, whence it was introduced into cultivation by Dr. Albert Regel, whose name it bears. Its botanical interest is considerable, as Mr. Baker points out, in its rudimentary crest and fully-developed beard down the claw of the outer segments of the perianth, thus forming a connecting link between the sub-genera, *Pogoniris* and *Evansia*.

Disa racemosa, t. 7021; a very handsome Cape species, with bright rose-red flowers.

Asarum macranthum, t. 7022; a native of Formosa.

Recent Publications.

Entomology for Beginners, for the use of young folks, fruit-growers, farmers and gardeners. By A. S. Packard, M.D., Ph.D. New York: Henry Holt & Co.

The modest title of this book hardly does justice to its scope. Many amateur entomologists who are neither young folks nor beginners will find instructive hints to aid them in collecting and rearing insects, in preserving and dissecting them for study, mounting them for the microscope and preparing them for the cabinet. It is for beginners, however, that the book has been primarily prepared, and those who wish to enter upon a course of serious study cannot find a better treatise upon the elements of entomological science. According to the classification adopted, the class of insects is divided into sixteen orders, beginning with the lowest or wingless order, Thysanura, and ending with the most complicated group, the Hymenoptera. This agrees not only with the succession of insects so far as this is known in geologic time, but it probably coincides with the order of evolution. This change in classification seems to grow naturally out of our increased knowledge, but Professor Packard points out that the adoption of a larger number of orders is most convenient in view of the great number of species now existing. There are something like a million of these, and it is unnatural to crowd them all into the old Linnæan orders. The chapter on

"Economic Entomology," gives brief accounts of the more injurious of the insects which annually destroy perhaps \$100,000,000 worth of the agricultural products of the country, together with the best means of checking their ravages. Throughout the entire work there are abundant references to other books, and there is a valuable classified catalogue of the books needed by the entomological student. The copious glossary and full index adds much to the practical value of the book, and altogether it ought to prove useful as a text-book for schools and colleges, and especially for agricultural colleges, and it will no doubt encourage a more general and more careful study of the modes of life, the transformation and the structure of insects, than has yet been given to the subject in this country.

Notes.

Apple blossoms are not unknown in autumn, but they are rarely seen in profusion. Mr. Dawson writes that in the last week of September one tree of *Pyrus baccata* was nearly covered with bloom.

The experiments made in the cultivation of the Cinchona on Mount Bavi, in the French province of Tonkin, having proved entirely satisfactory, it is now proposed to establish large plantations of these trees there.

The Philadelphia Chrysanthemum Show, which opens on the 13th and closes on the 16th of November, promises to be unusually fine, both in cut flowers and specimen plants. The cut Roses at that time will also be finer than are now to be had.

The French Society of Acclimatation recommends the cultivation of *Crocus Haussknechtii*, a Persian species for the production of saffron, on account of its superiority over the common *C. sativas* generally cultivated in some parts of the Levant for this purpose.

The old Scotch Rose (*Rosa spinosissima*) is now the most attractive of the black fruited kinds, and the wonderful shades of orange and scarlet worn by the hips of *R. rugosa*, *R. acicularis*, *R. rubrifolia*, *R. alpina*, *R. cinnamomea*, *R. subglobosa*, and *R. nitida*, ought to insure a more general use of these plants for the beauty of their fruit alone.

Mr. P. W. Reasoner died at his home in Manatee, Florida, of yellow fever, on the 17th of September. Mr. Reasoner, who was only in his twenty-sixth year at the time of his death, was one of the most active and progressive horticulturists of the South, and had already won for himself a reputation which extended beyond the limits of his adopted State. He was a welcome and valued contributor to the pages of this journal.

We learn from the *Gardeners' Chronicle* that, under the name of *The Orchidonne*, a society of amateur Orchid-growers was founded in Brussels on the 23d of September. The object of the new society is to foster the taste for, and promote the culture of, Orchids. This is to be effected by meetings and monthly exhibitions, lectures, and by a great annual exhibition, the first of which will be held next spring. There are seventy foundation members in the society.

The most interesting feature of the horticultural display made in Springfield, Massachusetts, last week, in connection with the Bay State Agricultural Society's Exhibition, was a collection of 250 varieties of Potatoes, including many seedlings, staged by Mr. G. C. Bond, of Holden, Massachusetts, and raised without other fertilizer than the Soluble Pacific Guano, manufactured by the Pacific Guano Company, of Boston. It is believed that this is the largest and most interesting collection of Potatoes ever exhibited by one grower in the United States.

The interest now taken in the cultivation of new and rare Orchids in this country, and the prices which Orchid growers are willing to pay for them, is illustrated by the fact that dealers are willing to incur enormous expenditures to satisfy the demands of the trade. Messrs. Siebrecht & Wadley, of New York, have had for nearly a year a collector traveling in Brazil for the special purpose of obtaining a supply of the rare autumn-flowering form of *Cattleya labiata*, besides other collectors constantly seeking for novelties in different regions of Central and South America.

The great Orchid growing establishment of the Messrs. Sander, at St. Albans, England, of which mention has often been made in our columns, has had a branch establishment

in this country for the past two years, their business being conducted in Jersey City, under the superintendence of Mr. I. Forstermann. Mr. Sander recently arrived in New York, and has selected a site at Summit, N. J., where he is building a number of Orchid houses. It is his purpose, before returning to England, to visit all the fine collections of Orchids in the western as well as in the eastern States.

Symplocos paniculata, a fine Japanese shrub which was described while in bloom in "Notes from the Arnold Arboretum," is now thickly covered with berries in small bunches. The fruit is a bright ultramarine blue, and makes the shrub conspicuous among those which are valued for ornamental fruit. Another comparatively new shrub, *Panax sessilifolium*, is now showing large heads of deep black fruit, which hangs on the branches long after the large compound leaves have dropped. The old-fashioned Snowberry is one of the few shrubs with white fruit. When growing in a deep, rich soil it has a rare beauty in autumn, and is a graceful plant at all times.

Some exceptionally large trees, of which mention was recently made in *The Garden* (England), are: A Yew tree in the churchyard at Down, which, at three feet from the ground, has a girth of twenty-eight feet, and preserves its branches and foliage well, although its stem is hollow and crumbling; a Purple Beech at Holwood House, which, at three and a half feet from the ground, measures eleven feet, with a height of fifty feet and a branch spread of seventy-five feet diameter; a Cut-leaved Alder on one of the Hollydale lakes, which has a circumference, at a yard from its base, of six feet and a branch spread of forty-five feet diameter; and an Ailanthus (a tree which is not often seen of large size in England) which grows at Down House, the former residence of Charles Darwin, and measures six feet and nine inches at two feet from the ground. A Eucalyptus, which was planted in 1880 in the gardens of Earl Jersey at Baglan House, is noted as having already reached a height of twenty-nine feet.

No shrub has been more popular this year than *Hydrangea paniculata grandiflora*. It has appeared in every direction, grown in pots and in beds, in single specimens and in groups often of very great extent, in cottage gardens and on villa lawns, and profusely in almost every large country place. Very showy when in bloom and blooming late in the season, it has certainly strong claims to the favor it has won. Yet it should, perhaps, be called an effective rather than a really beautiful plant. To some eyes the singular color of its flower panicles, shading from cream color to a dull pink, is its greatest attraction; but to others it wears an unwholesome look, as though a tint which should be stronger, or, at least, clearer and purer, had been imperfectly developed. This, however, is a question of taste. The only sure fact is that it is very possible to have too much even of a good thing, and that in certain places—as at Newport—there have undoubtedly been too many of these Hydrangeas. In passing a hundred villas it became very tiresome to see a hundred successive clumps of so conspicuous a plant.

At a meeting of the Social Science Association, held in Saratoga during the first week of September, a paper was read by Dr. Lucy M. Hall, of Brooklyn, on "The Sanitary Condition of Country Homes." Sixty-five farm-houses of an average type had been carefully examined by the speaker in the New England, Middle and Western States, and the conclusions drawn from her survey are well worthy of note, both by the farmer, who lives in such homes all the year round, and by the inhabitant of cities who depends upon them to furnish himself and his family with refreshment for mind and body during the summer months. Over half these houses, Dr. Hall asserted, were built on wet clay soil, and it seldom appeared that any regard whatever had been paid to questions of subsoil and drainage. Fifty-five per cent. of the houses, again, were too closely shaded, sunlight being excluded from almost all their windows or from every one. Piazzas were likewise too extensive, their roofs still further excluding air and light. Nor had the character of shade-trees been more carefully considered than their number and proximity. Barns and stables were found in much too close connection with the house, their average distance being in New England not quite twenty-nine feet. The result of all these various ways of disregarding sanitary conditions was shown by the "clinical history" of these sixty-five farm-houses for a period of several years. Fifty-five per cent. in New England had a record of typhoid fever, and ninety-three per cent. of lung troubles and diphtheria, while rheumatism was everywhere.

Taste in Florists' Arrangements.

NOT long ago we stated that florists and nurserymen might exercise a wholesome influence on public taste by paying greater heed to the intrinsic excellence of flowers and plants than to their novelty only. Another way in which they can render service in the same direction is in their arrangement of cut flowers and decorative plants. Public taste has greatly improved in this matter during the past few years, and the fact is chiefly owing to the influence of our florists, who have offered their customers better and better things before they were conscious of wanting them. The use of "set pieces" is growing less common; the wiring of short-stemmed flowers, once the universal rule, has been largely abandoned in favor of loose, natural-looking arrangements of long-stemmed blossoms, as much more durable as they are more beautiful; boxes of cut flowers, left for arrangement to their recipient's hands, are, perhaps, more frequently chosen for gifts than anything else, and whatever the disposition that is made of flowers, the necessity of an intermixture of foliage to subdue and harmonize their colors is becoming more clearly realized.

All these welcome facts are largely due to the development of good taste in the florist himself. Yet there is much still for him to learn—many needed lessons which he can impress upon the public. It is important, for example, that when the selection of loose, cut flowers is left to him, such varieties shall be chosen as are not merely individually fine, but well adapted for association with each other; and that attention should be paid to durability as well as to beauty. Of course, when arrangements for some special occasion, as a dinner or a ball, are in question, momentary effectiveness may outweigh other qualities, under the circumstances; but, in general, flowers should be so disposed that they can be preserved for a reasonable length of time. The demands of beauty alone would suffice to enforce this advice. We are so well aware that if cut blossoms are deprived of moisture they must immediately perish, that we involuntarily feel a sensation of distress which interferes with our enjoyment of their effect when they are visibly deprived of it. To place

them in baskets filled with moss is sensible, and therefore satisfactory, but to tie them on the cover of a basket or in bunches on the handle is not sensible, and therefore is in bad taste. A true lover of flowers, receiving such an arrangement, is tempted at once to take it apart and save the flowers—and to have his work immediately pulled to pieces cannot be a florist's wish.

As regards the association of foliage with flowers there is still much to be learned. It does not suffice that the green selected shall be charming in itself; it must suit the character of the flowers it accompanies or the effect will not be good. *Asparagus tenuissimus* and Maidenhair Fern are both lovely things, but neither of them suits all kinds of flowers, as the fashion of the moment seems to declare. Delicate flowers harmonize with the delicacy of such foliage; but the same is not true of the massive Roses and flaunting Orchids, with which we constantly see it grouped. The foliage of the flowers themselves is the best guide in the selection of that which shall be arranged with them. It need not be literally this, but it should be something analogous in character; and the cultivation and introduction of various kinds of foliage suitable for association with the flowers we most commonly employ in winter is a work worthy of the best energies of some intelligent florist.

"Set pieces" are, however, the most difficult things with which a florist has to deal. Theoretically they are all wrong; in fact they seldom seem even approximately right; and there are probably many lovers of flowers who wish they might be forever banished from sight. On some occasions they may seem to be indispensable, and then they should be as simple as possible in both form and color. A wreath or cross or a flat bunch from the top of which graceful sprays of foliage project, is infinitely better than a broken column, an inscribed cushion, an anchor, or any of those innumerable devices in which flowers are used, not for the sake of their own beauty, but to portray some object more or less allegorical. A wreath all of Violets or Pansies or white flowers, or of white flowers sparingly intermingled with those of a single color, is far more beautiful than one in which several colors are intermixed; one or two varieties of white flowers are far better than many varieties; and even in a "set piece" care should be taken to secure at least an approach to naturalness in the placing of the blossoms, and to display the beauty of their individual forms by some intermixture of foliage.

It need hardly be added that in any case when flowers are employed for decorative purposes, reliance should be placed on their beauty exclusively, and no attempt should be made to enhance it by the addition of other factors, as, for example, stuffed birds or masses of ribbon.

We are glad to be able to say that no florists in the world show to-day so much skill and good taste as ours. Nowhere, except in Paris, is there even an approach to the beauty of the flowers which we can buy in winter, or of the arrangements which we can have prepared for us. If we look, for instance, at the illustrations in English and continental horticultural papers we find them about on a level with those which were common here some ten or fifteen years ago; the "fancy basket" is there still in its prime, especially in Germany, and the most grotesque and puerile devices are praised as marvels of ingenuity and charm. We are far ahead, in our appreciation of simplicity and naturalness, if we take the testimony of our horticultural literature and the work of our best florists as the standard.

What is a Tree?

THIS question, although often asked, is not easily answered. There are shrubs so tall and so vigorous that they may well be considered trees, and there are trees so low and of such feeble growth that they hardly deserve the name of trees. Really there is no hard and fast line

which separates a tree from a shrub, and any classification of plants which attempts to separate trees from shrubs must be purely artificial, and, therefore, unsatisfactory. The best definition of a tree we have seen, and one that goes a long way towards answering this perplexing question, was presented by Mr. B. E. Fernow to the Botanical Club of the American Association, at its recent meeting at Columbus. "Trees are woody plants, the seed of which has the inherent capacity of producing naturally, within their native limits, one main erect axis, not divided near the ground, the primary axis continuing to grow for a number of years more vigorously than the lateral axes, and the lower branches dying off in time," is Mr. Fernow's definition of a tree, and it is a sound and philosophical one.

Planting for Autumn Effect.

Planting with reference to making the most of the autumnal change in the color of the foliage of many of our North American plants, and to producing brilliant pictures by harmoniously grouping together trees and shrubs which are specially beautiful at this season of the year, is a matter which has received as yet little attention. The field, nevertheless, is an inviting one, and a careful study of the material at the disposal of the American planter for the production of autumnal effects will well repay the landscape-gardener and the planter. Different species must be studied with reference to the colors they assume in autumn, and if the best results in picture-making of this sort are to be attained, the peculiarities of coloring in individual trees must be taken advantage of. With some kinds of trees, and they are often the most brilliant at this season of the year, like the Flowering Dogwood, the Tupelo and the Liquidambar, all individuals assume the same autumn livery, and there is little choice, therefore, between individual trees in this respect. In others, individuals differ greatly in the time of the turning of the leaves and in the colors they assume. Every one has noticed, in the case of the Sugar Maple, that on some individuals the leaves are all golden, while on others a portion are scarlet, or that sometimes the leaves on a single branch turn scarlet while the remainder of the tree is still green. Individuals of the Scarlet Maple differ even more than Sugar Maples in this respect. On some the leaves are pale yellow; on others they are green with scarlet margins; others are brilliantly scarlet; in western Massachusetts there is one tree of this species, now known from one end of the Commonwealth to the other, whose leaves turn from green first to deep, dark purple, and then to the most brilliant scarlet. There are individuals of the White Elm whose leaves barely change color at all before falling; in others they are bright yellow for many days. Individuals of the White Ash vary remarkably in this way. The leaves upon some trees turn to a deep, bronzy purple peculiar to this Ash, while in others they turn pale yellow and never show the real autumnal beauty of the tree. The Scarlet Oak is generally constant in its autumn colors; but individual White Oaks vary considerably, and the Black Oak varies still more.

It is noticed that the autumnal coloring of an individual tree, or even of a particular branch of a tree, is constant. If the leaves on a particular branch of a Maple tree assume a particular color one year, they will continue to do so, year after year, as long as the branch exists. If the leaves of a certain Oak are more brilliant than those of any of its associates, they will continue to be so year after year. Autumnal effects of foliage, as a whole, vary in different years, but whether, as a whole, its brilliancy is greater or less, certain individuals will always excel others in effects of color.

Planters, therefore, can well select and perpetuate these individuals in the same way that trees with abnormally colored leaves, like the Purple Beech, or with unusual habit of growth, like the Pyramidal Oak, have been perpetuated. The nurseryman who will propagate by grafting Maples or Oaks or Elms, selected with reference to

the autumnal tints of their foliage, will open the way to more effective plantations than have yet been made in this country, and will reap the reward of his intelligence and enterprise. The field, so far as we know, is entirely a new one.

The English are gradually being led—if we may trust the words of many writers in their horticultural journals—to abandon that bedding-out system which has long almost exclusively prevailed in their gardens, and to give more attention to hardy plants and informal arrangements. As a reaction in taste almost always, at its outset, leads those who favor it into extreme opinions and statements, we are not surprised to find that many of these writers go too far in their condemnation of carpet and pattern beds, granting to them no beauty and seeing no situations in which their effect is appropriate. Such is the case with a writer in a recent number of *The Garden*, whose interesting article is called "English Flower Gardens." Nevertheless, much that he says is well felt and well expressed, as the following brief extracts will show:

"It is evident that there is a growing taste for a more natural style of planting and a freer use of hardy plants in our flower gardens. It takes time to break down prejudices, even when they have little to recommend them. A transition period is necessary in many cases, and this we have been going through lately, as shown by the use of 'dot' plants on our hitherto flat and monotonous beds; but even this is not satisfactory, and the whole system must be swept away to make room for a better. Many and great are the difficulties which beset those of us who have at heart the better planting of our gardens. While deprecating the sameness and patterns of the bedding-out system and the extensive use of tender plants, we must not run to the other extreme and exclude many of our best plants on the plea that they will not stand our inclement winters out-of-doors. As well discard those hardy annuals which will not reproduce themselves in the soil where the seed fails without some sort of preparation, and the perennials, which want an annual division and an occasional renewal or manuring of the soil. . . . Variety is one of the great charms of the garden, of which we must not lose sight, and I, for one, should be sorry to discard many tender things. Who is there amongst us, having once seen a good bed of Heliotrope, would be induced to do without it in the garden? And yet it is one of our most tender plants. . . . But there are other gardens which have none of this formality, or where it can be easily swept away, and these are the places that gladden the hearts of those who are striving to give us something better than lessons in geometry, or in making thousands of plants look as nearly as possible like one. In these we shall see artistic grouping of flowering and ornamental foliaged plants here, there and everywhere, except in the positions most often selected, where they break up and spoil a fine stretch of landscape. . . . There are many gardeners who thoroughly understand the requirements of the plants under their care; but all are not able to make the best use of the material at hand, and before our gardens can be made beautiful this knowledge of plant life must be combined with the eye of an artist and the means of carrying out the requisite work. The great dislike to change arises from the fact that unhappy combinations may result in something offensive to good taste. The average 'bedding-out' gardener makes exact copies of some beds seen elsewhere and is safe. But this is not possible or desirable in artistic gardening, the end and aim of which should be the production of beautiful living pictures not seen quite in the same way elsewhere; they should be, in fact, masterpieces instead of copies."

Window Gardens.

THE practice of decorating windows with growing plants is growing in every part of the country, and a great diversity of taste is displayed. In some places we find, in a box that occupies the window-sill, a miniature flower garden, as great a variety as possible, and so crowded that individuality of form or color is entirely lost. The result is simply confused color, which is anything but pleasant. In another section we find boxes filled with Coleus, and where but one or two colors are used the effect is very good. With but one variety of Coleus, and the plants well grown and kept in proper shape, a window-box can be made beautiful. In other places we find boxes of Palms, Dracænas and the like, and these are often beautiful. Again we see boxes filled

with Ferns, and for shaded places nothing can be better. The Fern family is very large, but its members are usually congenial, and harmonize well together. It is an interesting fact that each town has a predominant style of gardening and window-gardening. Every one apparently follows the first striking example, and this emphasizes the importance of a good beginning. If the local florist makes a tasteful display, or some of the pioneers in planting give object-lessons in simplicity and naturalness of material and arrangement, the town will show this influence for years in attractive streets and lawns.

In London more good taste is displayed in the arrangement of window gardens than in any city or town I have ever visited. The first thing that attracts attention is the contrast of positive, well-defined colors; the next is the plainness of the boxes that contain the plants. These are conspicuous for what they do not show—color; in fact, they are made to hold the plants, and not to be seen. The plants principally used are the Paris Daisy (*Chrysanthemum frutescens*), Shrubby Calceolaria and some semi-double scarlet Geranium. The arrangement is quite simple. Usually there is an outer row of the Yellow Calceolaria; through the centre are, say, three scarlet Geraniums; the remaining room is filled with the Chrysanthemums. For window gardens, as well as for pot plants, the English florists grow the Chrysanthemum to perfection; they keep it dwarf and stocky, which is done by cutting well back when young, and never advancing the plants to a pot more than six inches in diameter. Occasionally a little Lobelia may be seen in some of their arrangements, but this only tends to intensify the other colors, making each more prominent.

These boxes are simple and inexpensive, and for effect nothing can surpass them. All the plants are not only adapted to the purposes for which they are used, but succeed admirably in their climate, making a cheerful contrast to the soot-colored houses. The use of these boxes is very general; in some of the streets nearly every house has its window-garden or box of flowers; I noticed many houses in which every front window had its flower-box. Flowers are not confined to the balconies of the great houses. In the humbler houses of the middle and lower classes the windows are bright with bloom. Only a few plants are seen in any one house, but wherever seen, the Chrysanthemum is the prominent plant, and, as there grown, a better need not be looked for.

C. L. Allen.

The Rainfall on the Plains.

TO demonstrate satisfactorily the occurrence of changes in climate is one of the difficult problems of meteorology, yet widespread beliefs in the occurrence of such changes have become prevalent in this country, and are firmly held by large numbers of the people.

Of such generally accepted beliefs is the one prevalent in Connecticut—that the spring is much later than it was a half century ago. The older farmers relate that when they were boys it was customary to begin planting corn on the day following General Training day, whereas, now, this stage of the farm work is delayed by the prolonged winters to a much later date.

A similar popular belief in a climatic change, current west of the Mississippi, is that their rainfall is increasing, and the cause of this increase is attributed to the extension of cultivation.

The widespread prevalence of this general impression is of itself an interesting and important fact, and claims the most respectful attention. For, if founded in accurate, although not on instrumental, observation, it will have a *raison d'être* that will go far to establish its truth. My own inquiries, however, have shown that, in general, the current belief in an increase of rainfall does not rest so much on observation as on a fallacious argument. Based upon the reports of early explorers, all the country west of the Missouri was believed thirty years ago to be a "Great American Desert," in which agriculture would always be impossible because of the insufficiency of rain. Eastern Kansas was then settled, and yet, for the first ten years, few believed that the frontier of settlement could ever be extended west of Topeka.

The stream of immigration, however, has pushed westward, and, as yet, no absolute limit has been reached. Holding to the essential truth of their old assumption, the older settlers explain this westward advance of agriculture as having been rendered possible by an increase of rainfall gradually produced by the tillage of the soil and the growing of trees. But this argument is fallacious because of its defective premise. The possibilities of the country for agriculture were underestimated by reason of the lack of the proper experience for forming an opinion. Cultivation has greatly added to the economy of the

rainfall, and has rendered possible the growing of crops on previously barren ground. Growth of grasses, tree planting, the prevention of disastrous prairie fires and general cultivation—these are the agencies that have wrought a change in the conditions of agriculture in Kansas.

All the change that has taken place may have been effected without an increase in rainfall of a single inch. The evidence of a change in the amount of rainfall cannot be concluded from changes in agricultural possibilities that have been brought about by an indefinite number of interacting causes, but must be based on direct and trustworthy observation.

The observational data available as evidence on the subject are very meagre, but conflicting views as to the conclusions to be derived from them have been abundant. During the past year especially there has been an active revival of interest in the question, and a galaxy of eminent writers has taken part in the discussion.

Upon the negative side of the question relatively little has been written, and for the reason, no doubt, that the burden of proof rests with those who believe in the increased rainfall.

Ex-Senator Dorsey, in the *North American Review*, says: "Nothing is more idle than the talk that can be heard on all sides respecting the rainfall increasing within what is known as the arid region. The rainfall has been accurately recorded as far back as 1847 at Fort Riley, Kansas; Fort Bent, Colorado; Santa Fé, New Mexico; Fort Bridger, Wyoming, and Salt Lake City. These records show that there has been no increase whatever in the past forty years.

"I challenge those who persist in claiming that what is now known as the arid region will sooner or later become productive by the natural rainfall to show a single instance anywhere on the surface of the earth where such a result has been attained. There has been no such climatic change on this or any other continent."

The five stations quoted by ex-Senator Dorsey as exhibiting no rainfall, are, however, with exception of Fort Riley, and perhaps Fort Bent, quite outside of the district over which the increase is generally believed to have taken place, and so are not pertinent evidence in the case. The observations at Fort Riley extend back to 1854 (not 1847), and exhibit an increase of two inches in the average annual rainfall of recent years over that of the first decade.

A similar conclusion to that of Mr. Dorsey has been presented by the eminent geographer, Mr. Gannett, in a recent article in *Science*, which has already received notice in the columns of this journal. He divides the observations from each of twenty-six stations (mainly in Kansas and Nebraska) into two equal terms, and adds the yearly rainfalls in each term separately. These two sums show no appreciable difference, whereupon he concludes that the observations show no increase of rainfall. This method pursued by Mr. Gannett might easily fail to show an increase of rainfall even if one existed. One-half the stations have short series of from three to twelve years in length, while the remaining are from twelve to twenty-eight years. If there has been an increase of rainfall it is to be discovered by separating the observations so that each portion shall cover different periods of time. Thus, if it is desired to ascertain whether the rainfall has been greater during the past ten years than during the period from 1840 to 1850, observations taken recently must be compared with those taken during the earlier period.

It is difficult to see how the mixture given by Mr. Gannett can possibly throw any light on the subject.

Mr. Charles Francis Adams, in the *New York Nation*, and General Greely in *Science*, are each disposed to believe that the rainfall has increased, but do not give any reasons that can properly form the basis of an argument. General Morrow, in an address on October 5th, 1887, at the Sidney Fair, advocated the popular view of an increase of rain due to cultivation, with the following argument: "I have always thought that there was an abundance of moisture in the clouds of the interior section of the country, but that conditions favorable to its precipitation in the form of rain and dew were wanting. The earth and the sky are reciprocal in their relations. They give to and take from each other. A parched desert having nothing to give in return receives no moisture from the passing clouds."

This is an attractive, poetical view, but it can be considered as a valuable argument upon the question only after it has been shown to have a rational, physical foundation.

The most valuable contribution of the year, in my opinion, is that by Professor Harrington, in the *American Meteorological Journal* for December, 1887. A careful comparison of the rainfall charts, based on the recent Signal Service observations, with the charts contained in Blodgett's "Climatology of the

United States," shows an unmistakable westward advance of the isohyetal lines over the western plains. By this method all of the data up to 1855, consisting mainly of the records at the military posts, is utilized for the first period, and the Signal Service records from 1871 to 1883 for the second period. The certainty of the conclusion seems, therefore, to depend mainly on the degree of accuracy with which the meagre data available in 1855 truly represent the average rainfall of so great a district, and on the comparability of these quite different series of observations. As a test of the latter question I have examined the contemporaneous records made at Fort Leavenworth and at the Signal Service station in Leavenworth City for the twelve years from 1871 to 1883, and find that the average annual rainfall observed at the fort was 33.0 inches, while that at the Signal Service station was 38.5 inches. To what this large discrepancy between the two sets of observations is due is not easily determined, but its most probable source apparently lies in the greater care exerted by the Signal Service to measure small rains and showers. If this be the true explanation, it applies to the comparison of all fort records with Signal Service records, and the conclusion of an increase of rainfall obtained by Professor Harrington would be quite vitiated.

The observations from Fort Leavenworth extend over nearly fifty years, and thus constitute the most valuable series west of the Mississippi River. This record exhibits an increase of two inches in the mean of the last two decades over the mean of the first two—an amount almost too small to be considered as giving evidence of any real or important climatic change. In fact, the rainfall record in many eastern cities shows an increase much greater than any that can be found in the West. In Philadelphia during the past forty years the measured rainfall has increased six inches, and at Providence and New Bedford eight inches. Has cultivation of the soil, tree-planting, railroad building or settlement been the cause of this large increase? And if not in these eastern cities, why is it so certain that they have been the cause of the possible increase of an inch or two in Kansas?

If settlement and cultivation and forest-growing can measurably increase the rainfall, how is it to be brought about? What is the *rationale* of the process? Who has shown that the assigned cause is adequate to produce the effect claimed for it? These important questions are seldom squarely faced. After very careful study of all the arguments and data that I have found it seems to me that the evidence of any material increase of rainfall in the West is very inconclusive, and, second, that, if such increase should occur, there would be, with our present knowledge, no sufficient evidence of its being due to settlement and cultivation.

Geo. E. Curtiss.

Parks and Squares of United States Cities.

THE nineteenth volume of the Final Reports of the Census of 1880, only lately distributed, completes the "Statistics of the Cities of the United States," and enables us to view the condition of 180 cities of the Union in respect to those necessities of modern town life—public parks and squares.

Two hundred and ten cities are enumerated. Of these thirty make no report concerning their public spaces, and may perhaps be presumed to own none, while forty state outright that they possess no public grounds whatever. Some surprisingly large towns appear in this latter class; for instance, Paterson, New Jersey (population, 51,000), Scranton, Pennsylvania (46,000), Wilmington, Delaware (42,500), Wheeling, West Virginia (31,000), Trenton, New Jersey (30,000), and many smaller but bustling places like Fort Wayne, Indiana, Poughkeepsie, New York, and Topeka, Kansas. Since the Census year several of these forty cities have taken steps to provide themselves with public spaces of one sort or another.

Turning now to the 140 cities which report one or more public grounds, we notice first the universal abuse of the word park. It is applied to every sort of public space, from the minutest grass-plot to the race-track or the fair-ground. The strict meaning of the word is completely lost. Hereafter we shall have to speak of country-parks when we wish to designate those public lands which the word park alone ought by rights to describe—*i. e.*, "lands intended and appropriated for the recreation of the people by means of their rural, sylvan and natural scenery and character."

Country parks are sometimes of small area, as when some striking glen, or river-bank, or cañon is preserved in its natural state (would this were oftener done!)—but generally an area of at least fifty or one hundred acres is required to provide a natural aspect. Smaller spaces can satisfy many of the de-

sires of the crowded city people—can supply fresh air and ample play-room, and shade of trees and brightness of grass and flowers—but the occasionally so pressing want of that quiet and peculiar refreshment which comes from contemplation of scenery—the want which the rich satisfy by fleeing from town at certain seasons, but which the poor (who are trespassers in the country) can seldom fill—is only to be met by the country park. If a few of the twenty-six cities which reported themselves in 1880 as possessed of large tracts of land have put these lands to uses for which small areas would have served as well or better—if they have given them over to decorative gardening, to statuary and buildings, or to other town-like things—they have made (unless the circumstances are peculiar) an extravagant mistake. For large open spaces close to cities are excessively costly, and one such interferes with traffic in far greater degree than do many small areas, so that no town can properly afford to own a large tract unless for the express purpose of providing refreshing natural scenery.

The accompanying table of the twenty-six cities which reported park lands of fifty acres and upwards presents curious contrasts. The first column gives the number of inhabitants per acre of park—which is the basis of the order of the names—the other columns the population and the park acreage:

18 Macon,	13,000	720
22 Council Bluffs,	18,000	600+104+90
166 Detroit,	116,500	700
172 St. Paul,	41,500	240
175 New Britain,	13,000	74
176 St. Louis,	350,500	1,372+276+180+158
182 Binghamton,	17,500	96
222 San Francisco,	234,000	1,050
280 Bridgeport,	28,000	50+50
281 Chicago,	503,500	593+372+250+200+185+180
309 Philadelphia,	847,000	2,740
310 Baltimore,	232,500	693+56
410 San Antonio,	20,500	50
417 Omaha,	30,500	73
442 Buffalo,	155,000	350
508 New Orleans,	216,000	250+175
680 Portland, Me.,	34,000	50
685 Cincinnati,	255,000	206+164
833 Indianapolis,	75,000	90
907 Fall River,	49,000	54
940 Allegheny,	79,000	84
1019 Providence,	105,000	103
1122 Brooklyn,	567,000	505
1213 Albany,	91,000	75
1400 New York,	1,206,500	862
3424 Boston,	363,000	106

Little Macon's large park was the gift of the State. It is mostly in large forest trees. Boston, at the other end of the list, boasts uncommonly attractive suburbs, which have served some of the purposes of a park; but she has lately begun work upon a real park of more than 600 acres.

Of small public grounds there appears to be an equally various provision. In New England many cities possess the remains of old town commons—for instance, Nashua (13,000) has forty acres in North and South Commons, and Newburyport (13,500) has the same; while Boston, Salem, Lynn and other places own larger or smaller areas of like origin.

At the founding of Philadelphia, five public squares of about six acres each were carefully reserved; but the example of the founders has been wofully forgotten by the builders of the great city of to-day. Savannah has done better, for she has continued the city-plan devised by her first colonists, and in 1880, with a population of 31,000, she had thirty acres in twenty-three public spaces, besides a ten-acre park and a twenty-acre parade ground. About the worst case reported is that of Pittsburgh, a city of 156,000 inhabitants and possessed of less than one and one-third public acres—a contrast to Buffalo (population, 155,000) which reported, in addition to the Park, fifty-six acres in the Parade, thirty-two acres in the Front and forty-two acres in eight pieces. Compare also the following:

Troy, New York (57,000), one acre. Richmond (64,000), sixty-five acres in five pieces.

Kansas City (56,000), two acres. Akron, Ohio (16,500), twenty-five acres in seven pieces.

Auburn, New York (22,000), one acre. Salt Lake (21,000), forty acres in four pieces.

And the remarkable case of Lawrence, Kansas (8,500), seventy-three acres in five pieces.

We have no fixed rule for the proper ratio to population of

the acreage or number of public squares, but it is safe to say that while a few of our cities are well provided for, a majority are still very badly off. New York is now tearing down buildings to make room for public gardens. Philadelphia, also, is endeavoring to make up for her past carelessness. Smaller places should secure the necessary lands before the cost becomes intolerable. A word in conclusion as to the laying out of public squares and gardens. The problem is wholly distinct from that of the country-park. Here and there, to be sure, is found a small public ground of such strongly marked shape and character that it by right rules its surroundings, whatever they may be—as the Back Bay Fens in Boston call a halt to the city structures—but small grounds in general are necessarily dominated by the formal lines of the streets and buildings which enclose them, and they must generally be shaped to a correspondingly formal plan. Every hope of a good general effect hangs on the securing of a good general plan. The famous Public Garden of Boston, recently criticised in this paper, fails of fine general effect because its frame-work or ground-plan was never thought out as a whole—as a design. The handsome and costly gardening which is to be seen there, the gorgeous beds and the fine specimen plants, cannot be fittingly displayed—can only be promiscuously scattered as they are—so long as the ground-plan of the garden remains the mongrel thing it is.

Boston. *Charles Eliot.*

New or Little Known Plants.

Phlox nana.*

THIS species presents one of the comparatively rare instances of great diversity of color in the wild state of an otherwise well defined species. From the readiness with which, in very many cases, color-breaks are induced in cultivated plants, it is very evident that color alone is of no value for distinguishing species. But in the ordinary course of nature, such variations are the exception, and species are in general, considering their capacity for change, wonderfully constant to their colors.

The *Phlox Drummondii*, in its native state, is said to be "red, varying to rose, purple and white," while under cultivation the range of tints has been greatly extended. *P. nana* shows not only various shades from red to white, but is remarkable in being sometimes of a pure bright yellow, a color not before known in the genus, though occurring in *Gilia* and *Polemonium*. In cultivation, therefore, there would seem to be here the possibility of obtaining rare combinations of colors, in what is in other respects, also, a very pretty species.

The plant is a rather low perennial, loosely branching from a somewhat woody base. It is a native of our dry south-western territories, from western Texas to southern Colorado and westward, and both purple and yellow forms were collected last year by Mr. C. G. Pringle in the mountains of Chihuahua.

S. W.

Orchid Notes.

Cattleya Exoniensis.—This superb hybrid was raised many years ago at the Exeter Nurseries, England, and was named after the city where it originated. The parents are presumed to be *Lalia crispa* and *L. purpurata*, as the habit and

*PHLOX NANA, Nutt.; Gray's Synoptical Flora, ii. 134.

Fig. 66.—*Phlox nana*.

inflorescence of the plants present an intermediate character between these two species. The flowers are about six inches across, and vary in color from almost white to a delicate rose. The sepals are narrow, while the petals are broad, with wavy edges and somewhat twisted at point. The lip, somewhat long, narrow, and much crisped, is white, with the middle lobe of the richest purple. The throat is yellow, streaked with purple.

This very fine plant is generally acknowledged to be one of the best of the genus, the exquisite lip being excelled only by *C. callistoglossa*, a hybrid also of *L. purpurata*. *C. Exoniensis* has always been in great demand, and it commands very high prices, but it will never become at all common unless new plants are raised from seed. Much care is required to keep this species in good health for any length of time, and when the plants attain any great size, they seem to become exhausted, and require to be broken up into small pieces and started again in small pots. The usual Cattleya treatment will suit it, but it should be in the coolest part of the house.

Phalenopsis Lowii.—This is a very distinct type of *Phalenopsis*. It is found growing on bare rocks in Moulmein, exposed to the full sun and subjected to extreme rains in the growing season, and so dry at other times as to cause it to lose its leaves. But in cultivation the plants never attain the strength and vigor to withstand such treatment, therefore every effort should be made to retain the leaves through the winter. This species grows very freely, producing abundance of roots. These seldom adhere to the block or basket, but spread in all directions, being often erect, consequently scarcely any potting material is required. It should have abundance of water at all times and the warmest and lightest part of the house. The flower spike is about one foot long, purplish, and bears five to ten round, light-rose flowers, one and a half inches across. The lip is narrow, of a deep rich purple. The column is very peculiar in shape, being bent downwards and prolonged into a proboscis-like appendage. *Phalenopsis amethystina* is also in flower. This plant is seldom seen, but the flowers are very pretty, and also interesting as being the smallest of the whole genus. It grows freely on blocks or in baskets with sphagnum moss.

Mesospinidium vulcanicum.—This attractive Orchid is now properly placed among the Odontoglossums. It is well worthy of cultivation, bearing slender, erect racemes of bright, rosy flowers, twenty to thirty in number, and about two inches across. The ovate, compressed bulbs have two stout, erect leaves, about six inches long. This plant is often seen in poor condition. Coming from the cool regions of Peru, it requires the same treatment as the Odontoglossums, especially as regards water, which should be given in abundance.

Keenwood, N. Y.

F. Goldring.

Lælia elegans.—Some of the choicest and most beautiful varieties of this fine *Lælia* are now forming a very attractive group in the collection of Mr. F. L. Ames, of North Easton, Massachusetts. The plants are in a high state of cultivation. The most striking of them is a well-flowered example of the extremely rare and showy *Lælia elegans prasiata*, having produced, from three stout growths, twenty-one handsome blossoms of great substance, size and color, and one of the finest forms we have seen. One spike was very remarkable, having borne as many as nine fully expanded flowers of considerable dimensions, the two others bearing six flowers on each. In color this variety is quite distinct from the ordinary type, having dull magenta-rose colored sepals and petals, with a broad, flat lip of a deep magenta-purple, which is very striking. It also emits a very powerful fragrance. Another very scarce variety is specially noticeable, named *L. elegans Turneri*, which is represented by a splendid, well-flowered specimen. This variety proves itself to be an excellent companion to the former, developing its blossoms at the same season of the year. One of the handsomest of all has just passed flowering, called *Lælia euphatha*. This is supposed to be a natural hybrid between *L. elegans* and *L. purpurata*. It differs somewhat in shape of flower, the color of its sepals and petals being of a fine rose, while the lip is a rich velvety purple. All the above varieties should receive the same treatment as *Lælia elegans*, with ample light and air while making their new growths. For years to come this *Lælia* will be one of the rarest of the genus, as it is rapidly becoming extinct in its native country, only very small plants being procurable, and that only after diligent search.

Jersey City.

Plant Notes.

Syringa pubescens.

OUR illustration upon page 415 of this issue represents a flowering branch of this very distinct and beautiful north China Lilac, which has now flowered for two years in the Arnold Arboretum, having been raised there from seed, for which that establishment is indebted to Dr. Bretschneider. *Syringa pubescens* is one

of the most distinct and most floriferous of all the Lilacs, being literally covered here, early in June, with its short panicles of small, long-tubed flowers, which are pale rose-colored and most deliciously fragrant. As seen in cultivation, it is a compact shrub, three to five feet high, with upright, slender branches, and rather small, ovate leaves, cuneate at the base, one and a half to two inches long, bright green on the upper, pale on the lower surface, the midrib covered with pubescence. *S. pubescens* is a native of northern China; it is perfectly hardy, and one of the most attractive and beautiful of new introductions to our shrubberies.

C. S. S.

Some Useful Plants of Southern California.

Romneya Coulteri.—Few will ask why this magnificent flower was made after once seeing it in full bloom—for the delight of their eyes will satisfy them. The *Romneya* Poppy is one of the most regal of our native flowers, and no flower yet introduced in our gardens excels it. Growing along the water courses on our southern border, southward to near San Quintin Bay, in Lower California, it wastes its sweetness and pure white loveliness unseen and unknown, except by a few. The wax-like flowers often exceed six inches across, the white petals set off to advantage by a centre of golden stamens. The stems grow from four to fifteen feet in height, rising above the surrounding brush, and when seen covering large areas and in full bloom the plant is not readily forgotten. Not content to occupy the fertile valleys, it seeks the most secluded cañons as well and often dots the hillsides, climbing far up the mountain-sides away from the reach of any but the most enthusiastic botanists. It seems to delight in these high, sterile locations, where it is thoroughly protected from the winds and is not likely to be disturbed. In cultivation the flowers become much larger and more wax-like, and it has long been in demand in Europe, where it was very early introduced. In addition to its horticultural attractions it possesses strong qualities of great medicinal value, which may secure for it a place in the materia medica when they are more fully investigated. It has long occupied a place among the medicinal herbs of the Indians of Lower California.

Simmondsia Californica.—This is a very common shrub in the southern part of the State, extending southward in the peninsula of Lower California. It was found by Dr. Veatch on Cerros Island, and was figured from that locality in one of the bulletins of the California Academy of Sciences. It forms low, oval bushes along the sea coast, often less than a foot in height when exposed to the ocean winds, and with its stiff leaves and branches and dense foliage forms impenetrable thickets in less exposed situations. The foliage is of a glaucous hue, blending harmoniously with the reddish soil on our hills and mesas, and in sharp contrast with the dark, olive-green foliage of the common *Rhus*, with which it is often associated. It rarely attains a height of fifteen feet, with a trunk diameter of four or five inches. Sometimes one standing alone forms a very symmetrically shaped tree, but it usually forms an oval mass with its dense foliage. The *Simmondsia*, as an ornamental shrub, is likely to meet with popular favor. Growing in fertile valleys and on barren hills, along exposed sea-cliffs and on the brink of the great Colorado desert, and equally tenacious of life whether in a situation of perpetual summer or where exposed to the snows of winter, it may be presumed that it will prove both hardy and easy of cultivation. The *Simmondsia* is a prolific bearer of an edible nut resembling an acorn both in size and shape. The resemblance is still further increased by the persistent calyx which forms a cup for the fruit. When ripe the outer envelope splits open and liberates the nut or nuts enclosed. They have a pleasant flavor, and I have frequently enjoyed eating them without any injurious effects. I am not aware that they were eaten by the Indians, but probably they formed an important article of food with them.

Prunus ilicifolia.—The Oak-leaf Cherry is one of the characteristic shrubs of San Diego County, and might, with nearly equal appropriateness, be termed the Holly-leaved Cherry, as the foliage is somewhat between that of our Shrub Oaks and the Holly. It is not rare both near the sea-coast and on the higher mountains bordering the sterile Colorado Basin, and some seasons it proves to be a very prolific bearer. Near the coast I think it is oftener barren than in the interior, but it grows rather more luxuriantly in some of the sheltered and fertile cañons near the ocean. As an ornamental shrub it is highly appreciated, especially for hedges, and is extensively planted for that purpose near Los Angeles, I am informed.

The glossy, dark evergreen foliage is always pleasing, and its dense, prickly character is an excellent feature. The fruit is of a dull, rather deep red when mature, oval in shape, often rather blunt at the ends, and an inch in length. A bush loaded with the fruit is a tempting sight, but it is rather aggravating to find the pulp scarcely an eighth of an inch thick. The stone forms the larger part of the fruit; but it is

Stuartia pentagyna, one of the most beautiful, when in flower, of North American shrubs, is described, in works upon American botany, as a native of the mountains of Georgia and the Carolinas. It is nowhere very common in these states, being confined principally to the banks of streams running eastward from the Blue Ridge. Now it appears that its real home is on the western foot-hills of the Big Smoky

Fig. 67.—*Syringa pubescens*.—See page 414.

still worthy of notice, and finds its champions among our country people, who calmly state that they prefer it to the grape. A basketful may be quickly gathered at the proper time if the season has been favorable, and possibly were not other fruits so abundant it might become of use for the table. I think I have seen it stated that the experiment of grafting cultivated Cherries on to this species has proved a success. If true, it certainly is of great value for cultivation, where it would be difficult to make other trees or shrubs grow successfully. Had we an agricultural experiment station in this section of the state it would be a proper subject to investigate.

San Diego, Cal.

C. R. Orcutt.

Mountains of Tennessee. Here this shrub literally lines the banks of all the small streams tributary to Pigeon River (which must not be confounded with the Big Pigeon, a more important stream further north), almost to the exclusion of other plants, forming dense thickets, sometimes fifteen feet or more high.

Aralia spinosa, the so-called Hercules Club or Angelica Tree, must be seen, too, on the western slopes of the Big Smokies, if its true beauty and character are to be understood. It is very common between three and four thousand feet elevation, growing in the richest soil in the neighborhood of streams and springing up frequently along the fences of

mountain farms. It attains a height of thirty or thirty-five feet, with a trunk sometimes eight inches in diameter, wide-spreading branches and a true arborescent habit. One of these large specimens, crowned with its enormous panicles of black fruit, is an object of remarkable beauty. The flowers are deliciously fragrant, recalling those of the common Lilac, and are highly valued by the mountaineers for their honey-yielding qualities.

The Seedless Barberry (*Berberis vulgaris asperma*) I never saw in such perfection of fruit as I saw it to-day in a Hampshire garden. It was one of the most beautiful sights I ever enjoyed in an autumn garden. There was a dense bush, eight feet high and as many in diameter, and every branch was loaded with hanging clusters of long berries of the most brilliant scarlet, which, with the foliage yet green, made a striking contrast. This seedless Barberry, though nothing more than a form of the common Barberry, is very superior in berry to any other. These are without seeds, very succulent, and make a better preserve or jelly than the other sorts. But as an ornamental shrub of the highest merit I would direct attention to it, for I can imagine nothing more beautiful on a lawn on a gray October day than such a bush of it as I saw to-day. It is an old variety known in the days of Philip Miller, who named it, and also by DuHamel, who, according to Loudon, spoke of the merits of the fruit for preserving. It is from this fruit that the celebrated *Confitures d'Epine vinette* are made at Rouen. It is not common in English gardens, and seldom seen in nurseries.

The Missouri Currant (*Ribes Missouriensis*) is at this season more conspicuous than at any other, for now its foliage, on the point of falling, is dyed with the most brilliant hues of crimson, blood-red and yellow. *R. aureum* also colors well, but is not so striking as the other, which is now grown largely at Knap Hill by Mr. Waterer expressly for planting for autumn effect.

Manure.

JUST as soon as crops are cleared off the ground we should cart or wheel out the manure on to it. When only a part of the ground can be cleared at one time, we can draw out the manure on to that part, and at the same time leave a heap of manure where it will be handiest for the yet uncleared part. So far as kitchen garden crops are concerned it matters little what sort of farm-yard manure is used, but for the cabbage tribe truck-gardeners have a prejudice against hog-pen manure, as they think club-root is more prevalent in land so manured than when cow or horse manure is used. Cow manure is preferred for light land and horse manure for heavy land. On light soil, hen or pigeon manure should be used very thinly, and always composted with earth or other absorbents, and rather in spring after growth commences than in fall. We use a large quantity of New York City stable-manure and find it excellent. As manure accumulates during the summer months we pile it up into solid heaps of any convenient length and breadth, but not over four or five feet deep, and drive the carts or wagons over the heap to compress the manure and save it from burning. Five feet may seem very deep, but as the manure rots it shrinks, so that what is five feet in May will probably be nearer three feet in October. The burning dries and deteriorates the manure, hence the advantage of shallow piles which catch and hold the rain. The manure-piles should be covered in summer with loam, when it can be conveniently procured. The horse-stable manure that accumulates during the summer we treat differently, having an eye to mushroom beds in winter and hot-beds in spring. The main object is to keep it dry, to prevent heating and rotting. We clear it away every day from the stables, therefore, and heap it into a high conical pile, which will shed the rain, so that the manure will turn over in fall almost as dry as straw in the barn. In fall we shake out the droppings, wet them, and treat them for mushroom beds. They will heat violently and make good material for that purpose, though not as good as manure that has accumulated in a stable-cellar or has been kept under the horses' feet in box-stalls for several days, so as to be well soaked with urine. Now this strawy litter that had once been wetted in the stable, then dried and kept dry in the pile, will, if wetted, piled and turned, make capital heating material for hot-beds; indeed, if we did not save the summer manure in this way we should be very short of hot-bed manure in spring. True, tree leaves, if gathered in fall, stored dry and kept dry over winter,

then wetted and heated in spring, are useful for hot-beds after the middle of March, though they have not strength enough for earlier beds.

Before carting out the manure on the land, we always turn it over and break it up fine, so that it shall spread well and be easily dug or plowed into the ground.

It is also well now to prepare manure and compost for mulching lawns and trees. Pretty well rotted farm-yard manure turned over loosely and broken up fine is capital top-dressing material for ordinary purposes, but in the case of impoverished lawns compost is better than plain manure, and should be applied in double or treble the quantity that we should use of manure. This compost consists of good loam and well-rotted, broken up manure in equal parts, or a little more of the loam than of the manure. Prepare a heap of this now by throwing the loam and manure on the pile together, then before it is used, say in November or December, turn it over to thoroughly mix and break it up. Some people have a strong repugnance to the use of manure or compost as top-dressing for lawns, claiming for it unsightliness and a bad smell, and they urge the use of commercial fertilizers instead. Now, no one would think of using fresh hog-pen or other malodorous manures as top-dressing. In the case of well prepared manure or compost a bad smell is barely perceptible, and after the first snow or rain there is no smell. The other objection on the ground of unsightliness is amply outweighed by the benefit of the top-dressing to the lawn. The dressing not only acts as a fertilizer, but also as a protection in winter, a consideration of the utmost importance in the case of short-cropped lawns, subject to freezing and thawing. We have many acres of lawn, the surface soil of which is little other than well-manured sand with a somewhat loamy skin which has been formed by repeated top-dressings of compost, and the subsoil is sand. This lawn keeps a sod of grass that could not be retained by means of artificial manures. On a lot of eight acres, also of very sandy soil, which was formerly top-dressed with manure every year and cut for hay, there has always been a fair first crop, and in the event of a moist summer, a good second crop. For two years we have pastured this lot, and the crop of grass—Red Top, mostly—it bears is extraordinary. Proper artificial manures are excellent in their way, especially in giving a brisk start to grass on loamy land, but for light or sandy land barn-yard manure seems to be preferable.

Wm. Falconer.

Roses.

THE hybrid Tea Rose, W. F. Bennett, seems to be coming into favor in some localities this season, though many growers, after giving it one season's trial when it was first introduced, were ready to discard it. But it is probable that its peculiarities were not thoroughly understood, and that the general failure with it during its first season was due to that fact.

The present opinion seems to be that this variety requires a special treatment, and that when properly handled it will pay for the trouble. When in good condition it certainly is a beautiful Rose, both in form of bud and in color.

It has been found that two-year-old plants almost invariably produce better flowers and have stronger and more rapid growth than yearlings, and in view of this fact a different system has been practiced with the Bennett, in several instances, from the usual mode of forcing Roses, and with better results. As is well known, in many of the large Rose establishments, all, or nearly all, the houses, are replanted each year. The Bennett should be treated on the same plan, with this marked difference, that with the majority of varieties young stock struck during the preceding winter should be planted; but with the Bennett the old plants may be lifted out of the beds or benches in which they have been growing for one season, and potted up into four-inch, five-inch or six-inch pots, as the size of the plants may require. This lifting operation should take place about March, and the plants grown afterward in the same manner as young stock, until the usual planting season arrives, when they should be replanted in fresh soil in the beds. With reasonable attention, they will make better growth and produce correspondingly better flowers than they did during the first season.

It may not be advisable to repeat this treatment with the same plants after the second year, as the plants may be too much exhausted after having been forced for two successive seasons to respond to a third trial. Of course it may be said that there is nothing new in this operation, and that it has been long practiced by a certain class of florists.

Still it may be a desirable piece of information for some one, when applied to the culture of the Bennett, and as such it is now offered. There has also been some difference of opinion as to the best temperature in which to grow the Bennett, and it may be stated that, in the experience of the writer, the best flowers have always been found at the coolest end of the house, where the temperature would not average more than 50° during cold nights. *H.*

Philadelphia.

The Forest.

New Forest Law for Italy.

IN Italy, on the 1st of May, 1888, a new forest law went into effect, in which full recognition of the established truths regarding forest influences, and the highest statesmanship, are both discernible. Although this new law is not as thorough-going as some of its advocates had desired, it is based on sound and liberal principles, recognizing individual rights, but recognizing, too, the right and duty of the State to prevent any exercise of individual freedom which injures the community at large.

The Government forests in Italy (116,000 acres, according to latest returns) comprise only 1.6 per cent. of the total forest area; the balance of over 7,000,000 acres belongs to communities, corporations and private owners. The forest law of 1877, recognizing the need of government protection to the agricultural interests, which were being injured by forest devastation and denudation of mountain-sides, had placed nearly one-half of this area under "forest bounds," or Government supervision, namely, "all woods and lands cleared of wood on the summits or slopes of mountains above the upper limit of Chestnut growth, and also those that from their character and situation may, in consequence of being cleared or tilled, give rise to landslips, caving in, avalanches, snowslides, and may, to the public injury, interfere with water-courses or change the character of the soil, or injure the local hygienic conditions."

In the latter case (hygienic considerations) it was optional with the communities to apply for Government interference, the communal or provincial forestal council having to determine whether the application should prevail, and the community being bound to indemnify the proprietor for any material damage that might result to him from having his property placed under "forest bounds."

Where reforestation was considered necessary, it was to be done at the joint expense of the Government, the provinces and the communities, and the right to seize, for reasons of public utility, in order to replant, was given to the forestal committee or council in each province, if the proprietor refused to do the work himself.

Under this law there were created forestal committees in thirteen provinces, with a yearly fund of \$4,000—one-half contributed by the general Government, the other half by the province—while the Forest Department tried to promote reforestation by giving premiums, distributing plant material and furnishing gratis advice through its foresters; the Government besides obligated itself to contribute two-thirds of the cost of reforestation to the reforestation associations, the formation of which was encouraged by the law.

Of the 76,000 acres, which were found to require reforestation for reasons of public safety, there were reforested during twenty years, from 1867 to 1886, under this and previous laws, 22,000 acres, the Government contributing \$85,000; the provinces and communities, \$95,000; private owners, \$35,000; the Government had, in addition, furnished 8,000,000 plants and 260,000 pounds of seed, free of charge. This was, indeed, slow progress, due to the absence of properly constituted authority to advance the work.

The devastating floods of the year 1882 produced a favorable feeling for more energetic measures, and the present law has been the result; a law evidently drawn with care and worth studying by our forestry reformers in devising measures soon to be needed here. It may certainly be considered the best law now existing in any country, for securing the benefits resulting to the community at large from a continuous forest cover of mountainous districts, liberal in spirit to individual owners, and yet placing the rights and welfare of the many above the willful and regardless exercise of private property rights.

The essential feature of the law, comprising twenty-one articles, may be briefly summed up as follows:

Article 1 declares the reforestation and *re-sodding of moun-

*The Commission which investigated the working of the French reforestation laws for the purpose of framing this law intelligently shows the value of re-sodding for purposes of binding the soil and regulating waterflow to be illusory. The decision whether reforestation or re-sodding is to be resorted to, is left to the Forest Administration.

tains and dunes as a means to restore their usefulness and to regulate mountain streams, a public and urgent necessity, to be undertaken under the charge of the Department of Agriculture. A list of the territory to be reforested, with estimates of the cost, is to be prepared by the Department, in co-operation with the Department of Public Works, and to be submitted to the owners of the land, who may make their objections to the proposed Government supervision, through the forestal committee of the province. If the Department, with the advice of the forest counselor and the counselor of public works, decides for Government supervision, the land falls under the regulation of the forest protective law of 1877, and their reforestation and management, under Government supervision, becomes obligatory. (Articles 2, 3, 4.)

The owners are permitted to associate themselves in order to undertake the work of reforestation co-operatively, and if the owners of three-fifths of the reforestation district, with a taxable value of at least one-half the total tax value, declare for association, it is legally so constituted. Yet association is not obligatory to the owners who wish to keep out of the association. They must, however, share in the general work and expenses, by which they may be benefited, or else they can be expropriated with suitable compensation by either the Government or the Association. This right exists also if they do not comply on their own property with the general plans of work. The owners in association contribute according to the tax value of their property and so do those outside the association for the general work—road making, binding of torrents, etc. Such associations are to have the same rights as associations for irrigating purposes and may borrow money at the low interest at which the soil-credit institutions of the State are loaning. (Articles 5 to 10.)

The Forest Department is to contribute to the extent of three-fifths of the total expense of the work of reforestation to associations and private owners, upon the condition that the plans for the work prepared by the Department be followed and the work be done in the specified time. Where the owners do not consent, or fail to do the work, the Department has the right to expropriate under the common law and perform the work alone. (Articles 11 to 16.)

The tracts thus acquired by the Government may be sold again before or after the work of reforestation is perfected, and the owners may reclaim their property within five years after reforestation, by paying the price paid them, together with the cost of work and interest on the same (Arts. 16 and 17).

The plans and regulations for the reforestation and management of the reforested grounds are prepared by the Forestry Department, to whom, yearly, a special fund will be appropriated for this work upon the basis of its report. (Articles 18 and 20.)

Article 19 allows the Department to restrict and regulate pasturage for the purpose of securing the soil and young growth in all mountainous districts, where such regulation seems called for, but it must pay a compensation to such owners as they are periodically prevented from grazing their cattle, and for any other damage in the use of their property they may eventually suffer.

It appears, then, that while the necessity for energetic measures is fully recognized, the law is careful to respect, as much as possible, individual rights. Free-will is allowed to determine the associated efforts, the Government simply determines the method and manner of work which it subsidizes, and undertakes the work itself only when private interest opposes itself to the common necessity. In Italy, as with us, the national idea is against the State owning property, and therefore the provision for selling the reforested area or returning it conditionally to the former owner, while under the French law, under similar circumstances, only a part of the expropriated property can be reclaimed from the government.

The proposition to release, as in France and Switzerland, the reforested land from taxes for thirty years was, after a lively debate, voted down, and the contribution to the work of three-fifths of the cost was substituted; the more reasonable motion, that the owners of land in the valley, who are decidedly benefited by the work on the mountains, should contribute towards it, was also lost.

The Department has already prepared the surveys and working plans for forty provinces, which contain an area to be reforested of 261,074 acres, at an estimated cost of \$4,640,000, while the remaining twenty-nine provinces will increase the area, it is estimated, to 534,728 acres, and the cost to a round \$12,000,000.

Thus Italy finds it necessary to tax herself in order to avert losses and dangers which the improvident clearing of moun-

tain slopes has brought upon her, while we, unable to learn from these experiences, allow the timbered lands of our public domain situated on the western mountain-ranges to be destroyed or sacrificed without adequate returns, and with the assured effect of injuring the agricultural lands below, which depend upon irrigation, and therefore upon the hydrologic influences of the forest-cover on the mountains. The failure to provide the appropriation of a few thousand dollars for an effective forest protective service now, will most certainly necessitate the expenditure of as many millions for reforestation in a not far distant future.

Correspondence.

Foreign Plants and American Scenery.

To the Editor of GARDEN AND FOREST :

Sir.—In GARDEN AND FOREST of August 1st, page 266, the law seems to me to have been laid down that the introduction of foreign plants in our scenery is destructive of landscape repose and harmony. No exception was suggested, and the word harmony was used, if I am not mistaken, as it commonly is in criticism of landscape painting, not of matters of scientific interest; not as if the question were one of what, in matters of literary criticism, is called "the unities."

That a fashion of planting far-fetched trees with little discrimination has led to deplorable results, no good observer can doubt. That these results are of such a character that we should, from horror of them, be led, as a rule, in our landscape planting, to taboo all trees coming from over sea, many of your readers will not, I am sure, be ready to admit, and if no one else has yet offered to say why, I will ask you to let me assume that duty.

Suppose anywhere in our Northern Atlantic States an abandoned clearing, such as in Virginia is called an "old-field;"—suppose it to be bordered by the aboriginal forest, with such brushwood as is natural to its glades and skirts straggling out upon the open;—suppose that mixing with this there is a more recent, yet well advanced, growth of trees and bushes sprung from seed, of which a part has drifted from the forest, a part from a neighboring abandoned homestead, while a part has been brought by birds from distant gardens, so that along with the natives, there is a remarkable variety of trees and bushes of foreign ancestry;—suppose a road through more open parts of the old-field, and that on this road a man is passing who, having lately come from New Zealand (or the moon), knows nothing of the vegetation of Europe, Asia or North America, yet has a good eye and susceptibility to the influences of scenery.

Now suppose, lastly, that this man is asked to point out, one after another, so that a list can be made, trees and bushes in an order that will represent the degree in which they appear to him to have an aspect of distinctiveness; No. 1 being that which stands out from among the others as the most of all incongruous, unblending, unassimilating, inharmonious and apparently exotic; No. 2 the next so, and so on.

The question, as we understand it, is essentially this: Would all of the trees and bushes that had come of a foreign ancestry be noted before any of the old native stock?

Some of them surely would stand high on the list, and some of much popularity, such as Horse Chestnut and Ginkgo and numerous sports of trees in themselves, at least, less objectionable on this score, as, for example, Weeping Beech and most of the more pronounced weepers; most of the Japanese Maples, also, and the dwarf, motley-hued and monstrous sorts of Conifers.

But, all? or, as a rule, with unimportant exceptions? So far from it, to our eyes, that we doubt whether, even of different species of the same genus, the visitor would not point out some of the native before some of the foreign—some of the American Magnolias, for example, before any of the Asiatic. We doubt if the European Red Bud, the Oriental Plane or the Chinese Wistaria (out of bloom) would be selected before their American cousins. It appears to us that *Rubus odoratus* would be noticed before *Rubus fruticosus*. Passing from the nearer relatives, it seems to us likely, also, that many of the European and Asiatic Maples, Elms, Ashes, Limes and Beeches would be named *after* such common American forest trees as the Catalpas, Sassafras, Liquidambar, Tulip, Tupelo and Honey Locust; that the American Chionanthus, Angelica, Cercis, Ptelia, Sumachs, Flowering Dogwood, Pipe-vine and Rhododendrons would be placed before some of the foreign Barberries, Privets, Spireas, Loniceras, Forsythias, Diervillas or even Lilacs. We doubt if the stranger,

seeing some of these latter bushes forming groups spontaneously with the natives, would suspect them to be of foreign origin, or that they would appear to him any more strange and discordant notes in the landscape than such common and generally distributed natives as have been named. We doubt if Barberry, Privet, Sweetbriar and Cherokee Rose, which, in parts of our country, are among the commonest wild shrubs, or the Fall Dandelion, Buttercups, Mints, Hemp Nettle and a dozen others, which, in parts, are among the commonest wild herbaceous plants, though it is believed all of foreign descent, would ever be thought, by such an observer, out of place in our scenery because of their disreputable and inharmonious influence. Two hundred years hence are not Japanese Honeysuckle, "Japanese Ivy" and "Japanese Box" (*Euonymus radicans*) likely to be equally bone of our bone in scenery?

The forest scenery of northern Europe is distinguished from most of ours by greater landscape sedateness. It is to be doubted if many of the trees that come thence to us, judiciously introduced among our own, provided they are suited with our climate, will not often have more of a quieting than of a disturbing influence on our scenery.

We have much ground which it is difficult and costly, with any plants natural to it, to redeem from a dull, dreary, forlorn and tamely rude condition. There are parts of the world where, in ground otherwise of similar aspect, plants spread naturally, of such a character and in such a manner, that the scenery is made by them interesting, pleasing and stimulating to the imagination—picturesque, in short. Heather, Broom and Furze are such plants in the British Islands. It happens that neither of these has yet flourished long with us, though it is said that Broom appears to have got a foothold in some of our exhausted tobacco lands. But if we cannot have these, it does not follow that nowhere in the world are there plants that would serve the same purpose with us. If any such offer, should not every American give them welcome? The Woad-waxen is a plant inferior to those above named as an element of landscape, but superior in cosmopolitan toughness. As a matter simply of scenery is such heroic settlement as it has effected (it is often winter-killed to the ground, but not to the root), upon the bleak, barren fells back of Salem, as lately described in GARDEN AND FOREST, a misfortune? We believe that to most persons it adds (and otherwise than through its floral beauty) much to the landscape charm of these hills, while detracting nothing from their wildly natural character.

Again, may we not (as artists) think that there are places with us in which a landscape composition might be given a touch of grace, delicacy and fineness by the blending into a body of low, native tree foliage that of the Tamarisk or the Oleaster, that would not be supplied in a given situation by any of our native trees?

Is there a plant that more provokes poetic sentiment than the Ivy? Is there any country in which Ivy grows with happier effect or more thriftily than it does in company with the native Madrona, Yew and Douglas Spruce on our north-west coast? Yet it must have been introduced there not long since from the opposite side of the world. Would not the man be a public benefactor who would bring us from anywhere an evergreen vine of at all corresponding influence in landscape that would equally adapt itself to the climatic conditions of our north-eastern coast?

Imagining possibilities in this direction, let us suppose that, from remote wilds of Central Asia or Africa, we should be offered an herb, or a close-growing, dwarf, woody plant like the *Leio-phyllum*, as it occurs in the Carolina Mountains, that would form a sod with a leafage never rising more than three inches from the roots and never failing in greenness or elasticity during our August droughts. Would not the matting of many a large, quiet, open space among our trees, with such a plant, favor harmony of scenery much more than it is ever favored by the result of the best gardening skill, aided by special fertilizers, lawn mowers, rollers and automatic sprinklers, in dealing with any of our native grasses? Such an acquisition we may think too improbable to be considered. But is it really much more improbable than, 200 years ago, would have been a prediction of the present distribution in some parts of our country of Timothy Grass, Red Clover and Canada Thistle, or in other parts of Bermuda Grass, Alfalfa and Japan Clover?

Before agreeing that no addition can be made to our native forest, except to its injury, we should consider that trees for landscape improvement are not solely those that please simply from their fitness to merely fall quietly into harmony with such as are already established. Trees would be of no less

value to us that, being adapted to our climate, would supply elements of vivacity, emphasis, accent, to points of our scenery, such as we see happily produced by the Upright Cypress and the horizontally branching Stone Pine when growing out of Ilex groves on the Mediterranean. And this is a reminder that some scholar has said that we can form little idea of what the scenery of Italy was in the time of Virgil from what we see there now. This because so many trees and plants, which were then common, have since become rare, and because so many, then unknown, have since become common. Is there reason for believing that the primitive scenery of Italy was, on this account, more pleasing than the present?

The large majority of foreign trees that have been introduced with us during the last fifty years, and which have promised well for a time, have been found unable to permanently endure the alternate extremes of our climate, but that there are many perfectly suited with it we have abundant evidence. Does the White Willow flourish better or grow older or larger in any of the meadows of its native land than in ours? Was it not under this tree that the most American of our poets sung of the family of trees, "Surely there are times when they consent to own me of their kin, and condescend to me and call me cousin," forgetting that, if so, it was the case of "a certain condescension of foreigners"? How is it with the English Elm, the Norway Maple, the Horse Chestnut? The Ailanthus, the Paulownia, the Pride of China, all introduced from Asia within the memory of living men, are spreading as wild trees and elbowing places for themselves in the midst of our native forests. The Eucalypti, from Australia, have come, in thirty years, to be a marked (not generally an agreeable) feature in the scenery of California, and while the climate of our Atlantic coast does not quite agree with the Hawthorns, in Oregon, notwithstanding its greatly drier summer, they seem to be as much at home as in Kent or Surrey.

But on this point of the adaptability of many foreign trees to flourish in American climates, only think of Peaches, Pears and Apples.

Frederick Law Olmsted.

Brookline, September, 1888.

[Mr. Olmsted's letter should be read with the greatest care and attention. No man now living has created so much and such admirable landscape, and no man is better equipped to discuss all that relates to his art. The position which GARDEN and FOREST has taken upon the question of composition in plantations made with the view of landscape effect is embraced in the following sentence, extracted from the article to which Mr. Olmsted refers: "It is certain, at any rate, that combinations of plants, other than those which nature makes or adopts, inevitably possess inharmonious elements which no amount of familiarity can ever quite reconcile to the educated eye." This sentence was written with special reference to the fact that in Prospect Park, in Brooklyn, various showy flowered garden-shrubs of foreign origin had been massed among native shrubs growing apparently spontaneously along the borders of a natural wood in the most sylvan part of the park. The effect which this combination produced appeared to us inharmonious, and therefore less pleasing than if the plantation had been confined to such shrubs as may be found growing naturally on Long Island in similar situations. How far the idea of harmony in composition in landscape is dependent upon association it is hard to say. Mr. Olmsted acknowledges that trees like the Ginkgo, the Horse Chestnut and the Weeping Beech would look out of place in an American landscape—that is, trees which have no prototypes in our natural, native scenery. But would the inhabitant of New Zealand or of the moon, whom we suppose to be totally ignorant of the vegetation of the north temperate portions of the earth's surface, find anything to jar upon his feelings in seeing a Weeping Willow or a Ginkgo or a Horse Chestnut growing with and among Hickories, Tupelos or Sequoias, which may be taken as the three peculiarly North American trees? Probably he would find the combination an appropriate and pleasing one, and no feeling of inharmoniousness would ever cross his mind. Foreign trees with American prototypes, like the Beech, Linn, Red-Bud, Plane, from which they can hardly be distinguished except by a botanist, do not jar upon the

sense of fitness when used in landscape planting here, because for all intents and purposes they are the same as our own species, except that, as a rule, they never grow here as vigorously; and, therefore, are less attractive objects. The European Oak, if it would grow here, might replace the American White Oak, which it closely resembles, anywhere, and this is true of almost every European tree which has an eastern American representative. We certainly did not intend to convey the idea that all American trees could be associated together harmoniously. One of the broad-leaved Magnolias of the southern Alleghany Mountains would appear as much out of place, from our point of view, in a northern landscape, as any tree from any foreign land could possibly do. This same Magnolia, however, amid the broad-leaved evergreens and luxuriant growth of the southern forests, seems to form an appropriate and necessary feature of the forest scenery. The fact that the Barberry in New England, the Cherokee Rose, the Pride of China tree, or the Ailanthus in the Southern States, when these plants are naturalized, and have been familiar objects for generations, do not look out of place in the landscape, confirms our idea that fitness comes not from similarity or dissimilarity of form or color or texture, but from mental association. When we have seen certain plants growing together often enough and long enough—that is, when they have been "adopted" by nature, to quote our own words—we become accustomed to the combination. It is only new and startling combinations which shock our mental susceptibilities. There is nothing more startling (and whatever is startling can form no part of a restful landscape) than to come upon an Apple-tree, as one may sometimes do in parts of New Jersey, growing in the midst of a thick Pine woods, and showing that the land had once been tilled. But if Apple-trees grew in our woods, and we had always seen them there, the combination would not seem an unnatural one.

The truth is that great masters of landscape construction can combine material drawn from many climates and many countries into one harmonious whole, but the masters of the art are not many, and the planter who is not sure of his genius can wisely follow nature in her teachings of harmony in composition. Had this reservation been made in the article referred to, our statement that "all attempts to force Nature, so to speak, by bringing in alien elements from remote continents and climates, must inevitably produce inharmonious results," would, perhaps, have been less open to criticism.—Ed.]

Notes.

Among Mr. Carman's hybrids between *Rosa rugosa* and the Hybrid Perpetuals, one has nearly thornless canes, and the foliage is clustered, remarkable in form and very dark.

The Chrysanthemum Show of the New Jersey Floricultural Society will be held in Orange, at the Harrison Street Rink, on Wednesday, Thursday and Friday, November 7th, 8th and 9th.

At a late exhibition in London were displayed flower clusters of *Hydrangea paniculata grandiflora* more than one foot in height and almost as broad, and they were cut from specimens planted in May last.

The New York Chrysanthemum Show will be held on the corner of Broadway and Fourteenth Street, in a large tent, properly heated. The exhibition will probably open on the seventh of November, and continue for a week.

Experiments at the Iowa Agricultural College Station seem to prove that when infested land is plowed up in order to bury the chinch bug, the furrow, to be effective, must be cut six inches deep, and when the land is not too hard, an inch or two deeper is advisable.

The City of Boston has recently acquired from the Commonwealth, through the Board of Harbor and Land Commissioners, about twenty-four acres of ground in the South Boston district, for the benefit of the public. It will be laid out at once, largely with reference to its use as a playground for children, all the central portion, or fifteen acres, being left open for that purpose.

The heavy storm which passed over Washington on the 16th of September did much damage to the green-houses both at the White House and the Botanic Garden. Many trees in the Botanic Garden were likewise injured and three well-known "memorial trees" destroyed. The Garland Elm, planted by the present Attorney-General, was split in two; the Buckeye, which was transplanted a number of years ago from the grounds of the late Vice-President Hendricks, was uprooted; and a Robinia, which commemorated President Garfield, was laid prostrate.

Professor Budd believes that alternating varieties in the Cherry or Plum orchard favors regular fruitage. A variety that might prove to be a very poor bearer when depending on its own pollen supply, may be found regularly fruitful when intermingled with other sorts. In our climate, if the weather during the blossoming period is hot and windy, a variety may mature and waste its pollen before the stigmas are ready to receive it. In such the pollen of adjoining sorts may perform the needed work with the aid of the insects or the breeze.

The current issue of *Insect Life* gives credit to W. W. Meech, of Vineland, N. J., the well-known author on Quinces, for the discovery that the ways of the common beetle (*Allorhina nitida*) are not altogether bad. He found the adult beetles eating the fungus *Ræstilia aurantiaca* upon his Quince trees. They even alighted upon it in the basket when he was gathering the fungus, and ate it greedily. Mr. Meech says "for this meritorious service I desire they should have full credit as among the insects beneficial." This beneficial habit, however, is more than counterbalanced by their appetite for fruit, to say nothing of the damage done by the larva.

A correspondent of the *Springfield Republican* considers the 600 square miles comprised in the Annapolis and Gasperau Valleys of Nova Scotia destined to become one great Apple orchard. One-tenth of this area is now planted with Apple trees, over one-fourth of these being young trees, and from 5,000,000 to 10,000,000 barrels will be annually produced in ten years. Under competition between American and English buyers the Apples sell for from three dollars to five dollars per barrel. About half a million barrels of Gravensteins, Baldwins, King of Tompkins, Nonpareils, Russets, Ribston Pippins and other choice varieties are now produced and exported every year. The fruit is of the best quality, the trees yield from three to seven barrels each, and trees are being planted at the rate of from 100 to 10,000 annually on each Apple farm.

According to the *Country Gentleman*, this season has been a favorable one in many places for heavy crops of Apples and Pears. The trees blossomed abundantly, but the fruit, when about a quarter grown, began to drop, to the great discouragement of owners. This proved, however, the best thing that could have happened, especially to Rhode Island Greenings, and to the Sheldon and Lawrence among Pears. It effected an excellent thinning of the fruit, and what remained developed into such fine specimens as are rarely seen. An expert estimate placed the quantity of Greenings in a portion of one orchard at forty bushels, and there afterwards proved to be more than a hundred bushels. For an estimate of five bushels of Lawrence Pears there were twenty-four. The Sheldons were superb and the Seckels large and fine. This result could be reached any year when an abundant crop is set by artificial thinning, without any diminution of the number of bushels.

The government has decided to abandon and sell the Custom-House and Sub-Treasury, on Wall Street, in this city, because of the insufficient size of the buildings and the great value of their sites. In the recent report of Mr. Fryer, United States Superintendent of Repairs for New York, it is recommended that land for the erection of new buildings should be taken on Battery Park, or, preferably, the Bowling Green. Certain local newspapers have interpreted this to mean that Mr. Fryer would like to see the buildings placed in one or the other of these parks, but we prefer to believe that his recommendation merely refers to sites facing upon them. After all that has been said of the deplorable lack of breathing-spaces in the lower part of New York, and in face of the Mayor's wise advice that they should be at once increased in number, it seems preposterous that any one can seriously think of saving government money at the expense of any of the little parks which now exist. The outrage perpetrated by the national authorities in placing the Post-Office where it stands, has not yet been, and never ought to be, forgiven. And a sister building on the Bowling Green or Battery Park would never, we feel sure, be permitted even by our long-suffering fellow citizens.

It is interesting to learn from English newspapers that General Prejevalsky, a distinguished Russian explorer, is about to try for the third time to reach the capital of the "Dalai Lama" in Thibet. Although this town—Lhasa—is only 300 or 400 miles from the frontier of India, not more than six or seven Europeans have ever set foot in it—and of these not one is alive to-day. The Russian general's first attempt was made through Mongolia and occupied three years. He was then forced to turn back when within twenty days' journey of Lhasa. About three years later, in 1876, he tried for the second time, but was again unsuccessful. Now he will make the attempt by the way of western and south-western Mongolia, and expects to be absent at least two years. The importance of his travels to naturalists is shown by the facts that from his first expedition he brought back five thousand specimens of plants, together with large collections of mammals, fish and insects; and that, taking all the collections together, about one-fifth of his specimens were found to be new to science. The country over which he will travel is extremely difficult and dangerous, and many of the tribes are fanatically hostile to Europeans. If he accomplishes his attempt, his account of Lhasa will excite the greatest interest, and if he returns in safety, even without reaching the capital, important additions to scientific knowledge may be expected.

The largest and finest collection of Orchids ever offered at public sale in this country by a nurseryman or dealer was disposed of by auction at the rooms of Young & Elliott, of this city, on Tuesday of last week. The sale included the entire stock which Messrs. F. Sander & Co., of St. Albans, England, had collected at their establishment in Jersey City, and consisted of more than 1,000 lots. The total amount realized was about \$7,000, and it would have been considerably more if the sale had been concluded. The day was too short, however, and some 200 of the lots catalogued were not reached. As a rule satisfactory prices were obtained, but some of the very finest Orchids sold for less than their real value. This was true of the superb specimen of *Vanda Sanderiana*, which brought only \$230. The original plant of *Cypripedium Boxallii atratum*, which was certificated by the Royal Horticultural Society of England, sold for \$160; *Cypripedium Chantinii*, Philbrick's variety, brought \$160, and a wonderful specimen of *Cattleya Mossia* sold for \$145. Perhaps the *Cypripediums*, all things considered, were sold to the best advantage. It was noted that the bidding was quite as brisk when darkness put an end to the sale as it was at the beginning. It was noted, too, that a larger proportion of the plants than is usually the case went to the trade about New York and Philadelphia, showing a confidence on the part of alert dealers that the demand for Orchids, and the best Orchids, is steadily growing in this country.

Referring to the popular idea that sulphur placed in holes bored in the trunks of trees will be dissolved and carried by the sap to the foliage in such quantities as to render it offensive to insects, a recent Bulletin of the Massachusetts Agricultural College Experiment Station says that it has been found upon cutting down trees which have been plugged with sulphur that the material remains unchanged for many years. It is added that while we are spending so much effort to prevent injury to our trees from borers we certainly ought not to make holes in them many times larger than those made by any known species of insect. In order to ascertain whether sulphur in soluble form can be introduced into a tree so as to affect the fungus growths causing rusts, blights and mildews, some large Rose bushes, badly mildewed, were treated with saturated solutions of potassium sulphide, hydrogen sulphide and ammonium sulphide. The liquid was forced into holes bored in the main stem with a small gimlet, and the orifice was plugged with grafting-wax. At first a slight improvement in the amount of mildew upon the leaves was noticed, but in September all the bushes but one were dead, presumably from the effect of the holes. Until further trials are made, this experiment indicates that while there may be some promise that antiseptics introduced into the sap circulation may prevent the growth of fungi, some safer means of introducing the solutions must be found. From the nature of the case it is hardly possible that any substance can be introduced into the circulation in sufficient quantities to affect insect life. Professor Maynard, who prepared the Bulletin, suggests that an inspection be made next season of the Elms in Boston which were bored and filled with chemicals last spring to make the leaves distasteful to beetles. Careful weighing would determine how much of the powder had escaped from the hole, and analysis could detect the presence of any excess of sulphur in the leaves.

Autumn Work Among the Trees.

ALL planting north of the latitude of this city is most safely done in the spring. Further south the long autumn enables trees, planted when the leaves are ripe, to push out new roots and establish themselves before the ground freezes. But where cold weather follows close after the early frosts a tree planted in the autumn has no opportunity to develop new roots, and therefore loses not only the advantage it would have obtained in a more temperate climate in an early and vigorous spring growth, but it is forced to endure the severity of the winter without the aid of roots in active working condition. Trees planted in the autumn do not always die in the Northern States; but they are more apt to suffer than those planted in the spring; they are often blown over unless carefully supported; and they are frequently heaved by the frost or thrown out of the ground entirely. But for all the operations connected with the planting and the care of trees, except the mere setting them in the ground, the autumn is the right time. All planting plans should be completed, and all stock selected, at this season, and the ground to be planted should be prepared and ready to receive the trees. Our springs are so short and the rush of spring work is always so pressing that it is impossible to properly prepare the ground for planting unless it is done during the summer and autumn. This is the time, therefore, when northern planters should decide what trees they want to plant next spring, and just where they will plant them. It is the time to select and order nursery stock; and if the planter has any facilities for protecting plants through the winter in a cold cellar or pit this is the time to obtain them from the nursery, rather than in the spring, when nurserymen are crowded with orders, and too busy to devote proper time and attention to digging and packing their trees. The ground being prepared, the exact position of each plant determined on and the plants on hand, the mere setting them in the ground is the work of a short time. The man, moreover, who is thus prepared beforehand for spring planting can take advantage of the first suitable weather, and get his plants into the ground as soon as the frost is

out and it is dry enough to work; while if he waits for material ordered in the spring, very often it will not be received until after the trees have started to grow, and warm, dry weather has set in. In a climate like that of our Northern States, where summer follows hard after winter, and where spring is almost unknown, there is no other operation of the farm or of the garden which demands more carefully planned preparation—more forehandedness—than tree-planting.

The autumn, too, after the leaves have begun to fall from the trees, is the best time to study plantations with the view of determining which trees should be removed, and which of those which are to remain need pruning. The actual condition of a tree—its health and shape, and its relation to its neighbors—is best determined after the leaves, or many of them, have fallen; and if trees are to be marked for the axe, it should be done now, and before really cold weather or snow makes the critical examination of each individual practically impossible. The autumn, too, as has been explained in a recent issue of this journal, is the best time for all pruning operations intended to rejuvenate old trees or to bring unsightly ones into shape.

The man, therefore, who has trees, should devote some portion of these autumn days to determining how he can improve them by thinning or by pruning, or, if he is a planter, in deciding where his next spring's plantations are to be made, and what they are to be made of.

West Indian Fruit Growing.

A LARGE part of the September issue of the *Kew Bulletin of Miscellaneous Information* is devoted to the consideration of the fruit-producing capacity of the Island of Dominica, a subject of very great interest to Americans in view of the immense development, in recent years, of the tropical-fruit business in the United States and of the probability of its much greater development in the future. From its earliest settlement Dominica has been celebrated for its fruit. As long ago as 1791 great quantities of Oranges and Lemons of excellent quality were sent from the island to England and the United States, and some of the neighboring islands, less fortunate in natural conditions, were supplied from the Orange groves of Dominica. Sixty different fruits, indigenous and exotic, are described as reaching perfection on the island, which "of all the British possessions in the Lesser Antilles is now regarded as having the best promise of the development of a large and remunerative fruit trade, not only with the United States and Canada, but also with Europe. The islands lying between Dominica and the mainland of North America, with the exception, perhaps, of the small colony of Montserrat, are not adapted for the cultivation of most of the tropical and sub-tropical fruits, by reason of the droughts to which they are sometimes subject. Thus it happens that Dominica is the nearest fruit-producing island of the Lesser Antilles to the United States and Canada, and it is also the nearest of the West Indian fruit islands to Great Britain. This is an important fact in regard to the future of the fruit trade between Great Britain and North America and the Lesser Antilles, for with so perishable an article as fruit even a few hours' curtailment of an ocean voyage means sometimes all the difference between profit and loss. Possessing a fertile soil, unsurpassed in any other part of the world, an abundant rainfall, and a wide diversity of climate, owing to the mountainous nature of the country, the capabilities of Dominica for the culture of tropical and sub-tropical fruits can scarcely be over-estimated."

In spite of its natural advantages the fruit business of Dominica is still in an unsatisfactory condition, the value of the total fruit exports for the year 1887 having been under \$50,000, which is about three times, however, the value of the export ten years before. This is due no doubt to the want of energy and enterprise on the part of the

planters, who seem to take matters very much as they find them, and are satisfied to conduct their business as it was done a century ago, to the neglect of modern methods and improved varieties. This is especially true of the Orange business throughout the West Indies, which largely depends for its supply of fruit upon "trees which have grown up, in most cases accidentally, in gardens, in odd corners of estates, and by the roadside." That West Indian Oranges are as good as they are is only an indication of the fitness of the soil and climate of the Antilles for the production of this fruit. If half the energy and intelligence which have been directed to the improvement and cultivation of the Orange in Florida could be given to perfecting this fruit in islands like Dominica or Jamaica, the result would be astonishing, both in the quality of the fruit produced and in the profits of the business. The little island of Montserrat, now the principal centre of the Lime-juice industry, shows how profitable tropical fruit-growing can be made when carried on under ordinarily good methods. This business on the island is constantly increasing, and has already assumed very important proportions, and Montserrat Lime-juice is now sent all over the world.

It may be added, in this connection, that the Lime-tree now grows spontaneously on the south Florida Keys, producing fruit of large size and the very best quality. The climate of these islands is better adapted to the cultivation of this fruit on an extensive scale than it is either for Pineapples—which, although grown there in large quantities, suffer during cold winters, and are very inferior in quality to those raised in the West Indies—or for Coconuts, which have lately been planted largely in south Florida. The Coconut, it is true, bears fruit at several places on the Florida coast, but the fruit is small and not of first-rate quality, and can never compete with that brought to our markets from Honduras and other Central American countries. Lime-juice factories on Key West or on the shores of Bay Biscayne might be made profitable investments, and would do much to develop the resources and prosperity of southern Florida.

The Charles River at Wellesley.

THE Charles River, which pursues a very devious course through the eastern part of Massachusetts and empties into Boston Bay, is, of all the rivers of New England, the one that is richest in poetical associations. The Hudson, with the grandeur of which it would be foolish to compare the humbler loveliness of the Charles, is more widely known through prose descriptions, and has not failed of its meed of poetical praise as well. But the Charles is so intimately associated with the lives and writings of so many poets, that even the Hudson hardly appeals as strongly to those who know and love the literature of our country. Our illustration is given to show the character of the stream at a point considerably removed from that where it becomes the broad estuary so well known to every one who has visited Boston—a point where it is truly the Charles of the poets. And the picture should have a double interest, as revealing how much a view of this sort may gain by being set, so to say, in a frame. This particular bridge, which serves to carry the water which supplies the City of Boston, is not especially to be commended for architectural beauty—its curve is somewhat too widely spread and the size of its arch-stones is hardly sufficient to give the desirable impression of sturdiness. But it serves the purpose of a frame for the landscape well enough; and it need hardly be added that effects analogous to those produced by its arch can be produced, when openings of a less diameter are in question, by the skillful planting or cutting of trees. Take away this frame, and we have a pretty bit of river, but scarcely a picture; and a picture may be made of the simplest outlook which has any elements of beauty, either natural or artificial, by supplying

a frame of the proper size and in the proper place, no matter what materials may be chosen for the purpose. Even a rustic gateway may be so built as to serve this purpose, and in the shaping and disposition of the windows of a country house results of this sort should be more often considered than they are.

California Woods in Autumn.

ALTHOUGH California lies wholly within latitudes which, in other lands, give marked changes of the seasons, yet here neither spring nor autumn is very definitely characterized; autumn less so than spring, if that may be called a vernal season which begins in November or December, comes to a halt in January, thence gradually advancing to its perfection in April, a half year after it begins.

Between July and November the face of nature undergoes but little change; and only the eye of the artist or naturalist will perceive the transition to autumn. The Dahlias, the China Asters and the late Chrysanthemums are in the gardens, blooming at the right season, too, and these give a little of the autumnal aspect to village and home, especially where late autumn fruits are ripening on the trees, and eastern Elms and Maples, planted along the streets, are shedding the yellow or brown leaf. But out among the hills it is scarcely so. The native trees, even to the Oaks, are chiefly evergreen; and even such Oaks as are really deciduous retain their foliage in full color until the dark rainy days of December, baring their gray trunks and branches not until the ground beneath and around them is bright green with fresh growing grass like that of spring.

There are, nevertheless, some autumnal wild flowers in California; and even a few trees whose altered foliage imparts, in September, an autumnal aspect to the tree-clad slopes of all mountainous and hilly districts. Wherever, in the near or distant landscape, a patch of deep yellow comes out in contrast with the dark but vivid green of Oaks and Bays, one knows it must be a clump of the native Maple (*Acer macrophyllum*); a tree distinguished from all others of its genus by the uncommon size of its leaves, which, in California, are half a foot broad on thrifty trees, in Oregon even larger. It nowhere makes up a forest, or even a small grove, by itself; only two or three in a place, or, at most, an interrupted succession of them, ranging up and down the course of a ravine or brook, are what one sees of this species in its native wilds. The foliage ripens and turns to yellow long in advance of the earliest frosts, so that before the equinox it is in its richest and decidedly autumnal garb.

In the higher Sierra only, and chiefly toward the northern boundaries of the State, occurs a smaller Maple (*Acer glabrum*), the leaves of which acquire an almost crimson hue as the autumn days advance; but this species is never met with in the more settled, western regions of California, with which we are concerned. The only red leaves here are those of the Wild Grape (*Vitis Californica*) and of the everywhere too prevalent Poison Oak (*Rhus diversiloba*). This last is altogether distinct from its east American analogue, having foliage of firmer texture and more rounded outline. In its autumnal dress it is truly beautiful, but this is taken on, at least in some parts of the country, as early as August, before we begin to think of the fall of the year. The same is true of another small deciduous tree, the native Horse Chestnut (*Æsculus Californica*), whose fading leaves of yellow and red-brown are sufficiently autumn-like, in whatever more elevated districts they do not fall before the end of summer.

With Asters and Golden Rods, Pacific North America is not well furnished. In the western parts of California we have but two or three species of each; and the most common of the Golden Rods (*Solidago Californica*) is almost gone before the autumnal days begin. One of the Asters (*A. radulinus*), a white-flowered, low species, with a simple flat-topped corymb crowning the leafy stalk, is met with along the borders of roads and thickets, but scarcely elsewhere. This also comes near being a summer flower; but it is in pretty condition in the early part of September. The blue-flowered species (*A. Chilensis*) is taller and more showy, quite like some of the eastern Asters, and it flowers quite late, growing chiefly in low, half marshy grounds, not far back from the sea.

The characteristic autumnal wild flowers of California are the various species of Madia and Hemizonia, known in everyday life by the not very promising appellation of Tar Weeds. With an abundant resinous hairiness, such as most of the kinds are invested with, they are not pleasant plants to handle or to walk among; but they grow in masses, on open hill-sides,

by streamlets in the woods, in stubble fields by acres, their white or yellow flowers giving color to miles of territory, but only in the early part of the day; for their broad and handsome rays, at least those of most species, wither like the corollas of Morning Glories, or Four O'Clocks, as soon as the sun is in mid-sky. The tallest species (*Madia elegans*) is a strikingly showy, Coreopsis-like plant, altogether neat and graceful, however offensive its tar-like stickiness is to the touch. The rays, one inch long and deeply three-lobed, are of a lively yellow, with a velvety red base. The heads are borne loosely and somewhat pendent at the ends of slender, almost leafless branchlets, the main stem standing six feet high or more. No lover of things beautiful can fail to admire the uncommon grace and coloring of this *Madia*, as it lightens up the roadsides and banks of streams through miles of mountain forests.

Afar from the fields and waysides, in deep mountain shades, where, after the drought of more than half a year, the streamlets are still flowing, one may find in October fine masses of flowers and ferns; not strictly autumnal plants, yet such as, at least, have the faculty of putting forth just now a second and a truly autumnal display of color. Such are two or three species of *Mimulus*. We shall find no scarlet to match that of the *Lobelia* of eastern brook-sides, but the *Mimulus cardinalis* is scarcely inferior to that; and the banks of *Mimulus inodorus*, often two feet high, and seeming like an overgrown, large-flowered and scentless Musk *Mimulus*, are a charming sight.

Another plant, one of the Saxifrage tribe (*Boykinia occidentalis*), with most elegant foliage and loose panicles of white or pinkish flowers, lingers in bloom from June until October. Here, too, the brilliant pendants of *Euonymus* and the large red globes of *Cornel* berries (*Cornus Nuttallii*), and the falling acorns of the California evergreen Chestnut Oak, all blend their sweet influences, and make us feel that, even in California, there are autumnal days. *Edw. L. Greene.*

Oakland, Cal.

The Centennial of the Fuchsia.

IF there is one plant which has reached the maximum of popularity it is certainly the Fuchsia. Every one knows this charming shrub, with its highly-colored flowers. In winter one finds it in the green-houses; it decorates our homes in spring, and in summer it adorns our gardens, and it may be seen in every window.

It is just a century since the first Fuchsia (*Fuchsia coccinea*) was introduced into Europe. Since that time travelers in the mountains of tropical America have discovered numerous varieties and brought back specimens. A. De Candolle, in the "*Prodromus*," mentions twenty-six species, which number was increased to forty by Dietrich in his "*Synopsis Plantarum*." Now there are fifty distinct species known.

As to the number of varieties which are the result of the crossing of these species it is impossible to get even an approximate idea. Mr. Porcher, in the fourth edition of his work on Fuchsias, published in 1874, describes or mentions more than 300 varieties, selected from the most beautiful. Few plants lend themselves so readily to hybridization. We cannot discuss these varieties here, as it would require a volume to mention them even, but it may be interesting for some of our readers to know the primitive type of the varieties which they cultivate, or, at least, the groups to which they belong. We shall briefly summarize, therefore, the different sections under which Fuchsias have been arranged, with a short description of the species which have been introduced.

De Candolle adopts the following classification:

FIRST SECTION.

Calyx-tube cylindrical or obconical, narrowed above the ovary; leaves opposite, verticillate or rarely almost alternate; ovules in two ranks in each cell.

1. *Breviflora*.—Tube of the corolla as long as or shorter than the lobes, stamens included.

2. *Macrostemonæ*.—Tube of the corolla as long as or shorter than the lobes.

3. *Longiflora*.—Tube of the corolla two or three times as long as the lobes.

SECOND SECTION.

Tube gibous at the base below the ovary; ovules minute, grouped without order about a central placenta; leaves alternate.

This section included a single species only, *F. exorticata*, when De Candolle published his monograph.

FIRST SECTION.

1. *Breviflora*.—This group is composed of species with small flowers, nearly all of which are in cultivation.

I. CULTIVATED SPECIES.

F. microphylla, a handsome shrub, with numerous devariate branches and abundant small red flowers.

F. lycioides, one of the first species introduced. Brought from Chili by Menzies about 1796, and now rarely cultivated.

F. thymifolia, a species near *F. microphylla*, from which it may be distinguished by its nearly entire pubescent leaves and by its greenish sepals.

F. bacillaris, a dwarf species, with bright rose-colored flowers, the petals broad in comparison with the sepals.

F. cylindracea, with cylindrical flowers.

F. acinifolia, with very small leaves. Introduced about 1840, and now lost from gardens.

II. SPECIES NOT INTRODUCED.

F. tetradactyla, Guatemala.

F. Notarisii, Mexico.

F. spinosa, Chili.

2. *Macrostemonæ*.—In this group, which has few representatives, there are a small number of species in cultivation.

I. CULTIVATED SPECIES.

F. Magellanica (*F. macrostemma*, Ruiz and Pav.), first introduced under the name of *F. coccinea*. Several forms of this plant have been described by different botanists as species, and have been introduced into cultivation. Among them are *F. conica*, so named on account of the shape of the calyx; *F. globosa*, named from the shape of the flower buds. According to Don, this variety was raised from the seed of *F. conica*. It is possible, if this plant is only a variety, that it was obtained accidentally, although it is certainly found in a state of nature. Some authors are of the opinion that it is a native of Chili, and I have found it myself in May, 1876, in New Grenada. It is the only form of *F. Magellanica* that I saw growing wild. There is reason to believe, therefore, that it is not a hybrid, and the fixity of its characters will cause it to be considered, perhaps, a species. *F. discolor*, *F. gracilis*, and its variety, *F. decussata*, *F. recurvata*, *F. araucaria*, are also considered to be spontaneous varieties of *F. Magellanica*. The hybrids of these varieties obtained by cultivation are now innumerable. To this section also belong *F. coccinea*, a Brazilian species (*Botanical Magazine*, t. 5, 740), which was for a long time confounded with *F. Magellanica*; *F. arborescens*, which looks like almost anything rather than a *Fuchsia*; *F. racemosa* and *F. syringiflora*, varieties of this species, which is a native of Mexico; *F. alpestris*, a Brazilian species, with large leaves and inconspicuous flowers, rare; *F. peniculator*, near *F. arborescens*, was introduced from Guatemala in 1856, and is rarely seen in cultivation.

II. SPECIES NOT INTRODUCED.

F. ovalis, of Peru; *F. pubescens*, Brazil; *F. integrifolia*; *F. radicans*, Brazil; *F. verrucosa*, New Grenada.

III. *Longiflora*.—A group containing the largest number of species, most from the north-western part of South America, and corresponding to Endlicher's sub-genus *Fuchsia*.

I. SPECIES IN CULTIVATION.

F. corymbiflora, a species with large leaves and terminal clusters of dark red flowers. There is a variety with white flowers.

F. Boliviana, a species near the last, and introduced into England about a dozen years ago, and about which little is known.

F. fulgens, a showy Mexican species, with denticulate leaves and long vermilion-colored flowers hanging from the extremity of the branches.

F. dependens, near *F. corymbiflora*, but with smaller leaves in fours.

F. apetala, a species with apetalous flowers, less known than the following.

F. mærantha, discovered in Peru by Mathews, and by Lobb in Colombia, who sent it to Europe. Its flowers, without petals and with a very long, dark-reddish purple calyx, are very beautiful; unfortunately the plant is delicate.

F. petiolaris (*F. miniata*, Planchon and Linden), a native of New Grenada, with axillary flowers with a purple vermilion calyx and small red petals.

F. bensta, a species near the last, with vermilion-orange undulate petals; discovered by Humboldt and Bonpland, in New Grenada.

F. serratifolia, a handsome shrub, with bright, rose-colored axillary flowers. This species, a native of Peru, has furnished our gardens with many varieties.

F. spectabilis, introduced from Ecuador about 1848; distinguished by the length of its reddish-purple calyx tube. The spreading petals are vermilion.

F. splendens, a Mexican species, with the reddish-purple calyx tube contracted at the base, with green sepals and yellowish petals.

F. cordifolia, discovered in Guatemala by Hartweg, who introduced it into Europe. Near *F. splendens*, from which it may be distinguished by its cordate leaves and longer flowers.

F. penduliflora, a recent introduction; the flowers in axillary and terminal clusters; the calyx-tube crimson flushed with chestnut.

F. sessilifolia, a handsome shrub with long racemes of pendulous flowers, and with oblong-lanceolate, sessile leaves; a native of Colombia.

F. simplicicaulis, a species near *F. corymbiflora* and *F. dependens*; calyx-tube bright rose-colored; petals scarlet.

F. triphylla, the oldest species of Fuchsia known; flowers axillary and in terminal clusters of a uniform scarlet; leaves in threes.

F. caracaseensis (*F. nigricans*), is no longer in cultivation.

F. ampliata, a superb Peruvian species, with large, vermilion flowers.

II. SPECIES NOT INTRODUCED.

F. confertifolia, Peru; *F. Hartwegi*, near Huambia; *F. hortella*, Colombia; *F. sylvatica*, Ecuador; *F. umbrosa*, Ecuador; *F. canescens*, Colombia and Peru; *F. seabrinacula*, Peru; *F. agavacensis*, Peru; *F. ampliata*, superb species of Peru; *F. quindensis*, Quindio; *F. longiflora*, Andes of Q., rare, beautiful species to introduce; *F. loxensis*, Peru; *F. corollata*, Colombia, a very ornamental plant; *F. curviflora*, Colombia; *F. denticulata*, Peru; *F. memlezanacea*, Caracas; *F. salicifolia*, Peru.

SECOND SECTION.

In this section, for a long time, one species only was known; it was cultivated under the name of *F. excorticata*. Its strange flower was more peculiar than attractive, and it has been almost entirely dropped. To this species another has since been added under the name of *F. procumbens*, also interesting solely on account of its peculiarity. These two species are natives of New Zealand. An intermediate form between *F. excorticata* and *F. procumbens*, also found in New Zealand, and called by Hooker *F. Colensoi*, had not been introduced. This last Fuchsia concludes the list of known species.

In traversing the mountains of South America, pre-eminently the country of Fuchsias, I met with a number of these species, and was able to secure numerous specimens, amounting to twenty-two varieties. Sixteen had been gathered by travelers before me, two are new, and four cannot be decided upon, as the specimens are incomplete.

My new species are (1) *F. vulcanica*. Branches, leaves and peduncles covered with short, thick, white, bristly pubescence. Branches rounded with short segments, sessile, or nearly sessile, leaves, in threes or fours, elliptical or obovate, abruptly pointed, sparsely toothed, flowers few, solitary, axillary; peduncles short; ovary oblong, calyx red (?) bristly, especially in the young flowers, tube slightly curved, gradually enlarging from the base to the summit; lobes oval-triangular-acuminate; corolla glabrous, bright cherry-red, petals rounded, a third shorter than the sepals, stamen and style exserted. Volcano of Azufra (Colombia).—This Fuchsia is related to *F. ampliata* by the character of its flowers, but differs from it in a remarkable pubescence, perhaps unique among Fuchsias, and by its sessile leaves and by many other characters. (2) *F. scherffiana*.—Rounded branches, delicately bristled, leaves opposite or alternate, petiole with short bristles, full grown blade lanceolate—oblong, acuminate, very obscurely toothed, sciliate, with short bristles on the midrib and secondary ribs of the upper side, and on the midrib of the under side; almost glabrous elsewhere. Flowers few, solitary, axillary; peduncles slender, covered, like the oblong ovary, with a few short hairs. Calyx almost glabrous, ovary red, tube narrow and cylindrical from its base for a third of its length, then gradually enlarged and again cylindrical; lobes oval-lanceolate, long-pointed; corolla, scarlet; petals, oblong-elliptical; the point round cuspidate, a little shorter than the calyx. Stamens and style exserted.

An intermediate species between *F. petiolaris* and *F. triphylla*, distinguished from the first by its very elongated

leaves with rather short petioles, its oblong ovary, its smaller sepals and its glabrous petals without hairs; and from *F. triphylla* by its more elongated leaves and its flowers, which are few, larger and not in clusters at the ends of the branches.

The sight of the beauty of these flowers as they grow in their native land awakened the desire in me to see them more widely cultivated. By new crossings of wild species, interesting hybrids would certainly be obtained, and old varieties, of which the characters always turn in about the same circle, would be rejuvenated. *Ed. André, in Revue Horticole.*

Foreign Correspondence.

London Letter.

AS autumn advances the fortnightly gatherings of the Royal Horticultural Society become more and more confined to open-air flowers; and hot-house plants and flowers, especially Orchids, are fewer at each meeting. At last Tuesday's show the flower exhibits consisted mainly of Dahlias, which were represented by every class, and made a brilliant display. To these were added a magnificent group of hybrid Cannas from Messrs. Cannell, about which I wrote some time since; some excellent late Roses from the Waltham Cross roseries; a large and most interesting group of Pitcher plants (*Nepenthes*) from Mr. B. S. Williams; and a marvelous array of that splendid bulbous plant, *Nerine Fothergillii major*, from the garden of Baron Schroeder, which is as famous for its Nerines as for its Orchids. Fruits are, of course, one of the predominating features of the autumn meetings, and on this occasion Messrs. Veitch exhibited a fine collection, rich in varieties of Plums, Apples, Pears, Figs and other fruits, which proved a great attraction.

The certificated flowers and plants were more plentiful than usual, most of them being new sorts of Dahlias, chiefly of the show and fancy classes. I will not attempt to describe them fully, that being nearly impossible, as they differ so slightly from each other and from older sorts, while their tints are in most cases so subtle that one cannot invent terms for them. Of the true show and fancy types, the large and globular flowers with shell-like florets arranged with faultless symmetry, a large number were considered worthy of certificates of the first class. Of these Mr. Turner, the famous Dahlia raiser and grower at Slough, sent the following: Maud Fellowes, white florets tipped with purple; Admiration, crimson tipped with white; Hugo, crimson; Agnes, rich yellow. From another raiser came John Cooper, a large and superbly shaped flower, buff flaked with purple. The well-known Dahlia growers, Messrs. Keynes, of Salisbury, secured a certificate for their Matthew, an orange-yellow flower. The Pompon or Bouquet class was represented by numerous new sorts. Mr. Turner's certified sorts were: Vivid, scarlet; Juliette, pale yellow tipped with bright red; and Lothair, orange-red and crimson; while Messrs. Keynes showed Little Ethel, white; Little Darkie, maroon crimson (almost black); Whisper, yellow tipped with buff; Eurydice, purple tipped, with pink florets. The Juarezii, or Cactus flowered section, which is perhaps at the present time the most popular class of Dahlias among us, was represented by some new sorts of distinct and sterling merit, but only two were considered worthy of certificates. These were both from Messrs. Keynes; their names being Honora, a large flower of a bright, clear yellow; and Panthea, a delicate shade of buff yellow. Most numerous of all the classes, because so easily raised, is the single Dahlia, of which there was an endless array of new sorts submitted. The committee, however, do not award certificates for single flowers, except in special cases, because there are already in cultivation such a multitude of really fine kinds of all colors. The only sort certificated on this occasion was one called Lady Montefiore, a finely shaped flower with broad, flat florets of a clear yellow tipped with crimson.

Among other plants certificated was Geoffrey St. Hilaire, shown by Messrs. Veitch, one of the finest of a new race of hybrid Cannas which has been brought into notice recently. It has broad and large leaves of a rich, dark, vinous purple tint, while the massive spike of large flowers is of a brilliant orange-scarlet. It is one of the finest of those recently exhibited. When well grown it is fully five feet high, and makes a stately, fine-foliaged plant, and, like the others, flowers for weeks in succession. A second Canna certificated was that named Paul Bert, shown by Messrs. Cannell, of Swanley. It is not such a fine variety as the last named, but its brilliant scarlet-crimson flowers, borne on large spikes, were very effective. It is a fitting companion to the several new varieties for which Messrs. Cannell have won certificates this season. There is, without question, a bright future for this new race of stove and green-house plants, which, in a warm and dry climate, would flourish out-of-doors.

Nerine excellens, a bulbous green-house plant of great beauty, was worthily certificated. It is a near relative of *N. flexuosa*, a delicate growing kind with wavy petals, whereas the flowers as well as the trusses of *N. excellens* are larger and are of a soft rose pink barred with crimson red. It is as easily grown as the rest of the Nerines.

A Himalayan Lily, *Lilium Wallichianum*, came, as did the Nerine, from Mr. Ware's nurseries. It is an old and tolerably well known Lily, but not of the highest merit, inasmuch as it is capricious under culture. It is not hardy enough for open air culture exclusively, yet it dislikes artificial warmth. The flower itself is beautiful, being about eight inches long, with a slender tube and a wide-spreading mouth. The sepals are of ivory whiteness, but the tube is greenish. It grows about a yard high, and each slender stem bears a solitary, fragrant flower. It is a Lily for specialists; not for general culture.

A very handsome Composite from Colorado, *Aster Townshendii*, or, as it is also called, *A. Bigelovii*, proves itself one of the finest of all our hardy Michaelmas Daisies, and the committee did right in stamping it with a certificate of merit, though it can scarcely be called a new plant, having been in English gardens for over a dozen years. It has flowers about two inches across, with a broad, yellow disc, and long, narrow ray florets of a bright purple. It blooms very freely, numerous flowers being borne on the slender stems, which rise about two feet high. It is, with us, a true, hardy perennial of the highest merit.

Another Composite, also a hardy, herbaceous perennial from Mr. Ware, was certificated. This was a semi-double variety of the now well known *Harpalium rigidum*, a North American plant, one of the finest hardy perennials we have. The new kind (named Semi-plenum) has large flowers, with the florets so much multiplied as to appear to make a double flower. It is quite as vigorous and as free flowering as the type, while the yellow is brighter.

The last certificated novelty was a narrow-leaved form of the common garden Beet, named McGregor's Favorite. The leaves are about an inch broad by six inches long, and of a deep, bronzy crimson. The habit of growth is tufted, and not so coarse as that of the common edible Beet. It was certificated purely as an ornamental plant, as it is thought that it will be useful for the flower garden, especially in working out designs.

Among the other exhibits, the most noteworthy was a fine group of hardy shrubs from the Messrs. Veitch, which comprised such choice things as *Cratægus Pyracantha Lalandei*, with branches thickly laden with scarlet berries, brighter and more numerous than in the old kind; *Berberis Thunbergi*, which, however, was not shown in fine condition, the berries being few and the bushes not in vigorous health; *Daphniphyllum glaucescens viridis*, a variety with greener leaves than the type and quite as handsome. Among the cut Roses were blooms of such lovely sorts as The Bride, Sunset, Papa Gontier (which has at length reached us from America), Grace Darling, Grand Mogul, Lady Mary Fitzwilliam and Madame Gui-

noisseau, all of which are new or little known sorts that carry excellent autumn flowers.

Mr. B. S. Williams' group of Pitcher plants represented, for the most part, the pretty hybrids raised some years ago by Mr. Taplin in New Jersey. These are at once recognized by their small, neatly shaped pitchers, generally highly colored, and always borne in profusion. Those named Williamsi, Hibberdii, Amabilis, Morganiæ and Henryana are typical of this fine hybrid race, and are becoming quite popular in English hot-houses, being so much more easily grown than other Pitcher plants.

London, September 30th.

New or Little Known Plants.

Hibiscus lasiocarpus.

THE present figure represents one of a group of tall, large flowered American species of Hibiscus, which have been somewhat confused. Their distinguishing characters, as they have been defined by Dr. Gray, consisting mainly in difference of pubescence and color, are such as cannot well be shown in an illustration, so that our figure might be referred nearly as well to any one of the species as to another.

The swamp Rose-mallow, *H. Moscheutos*, is the most common of these, being found through the eastern United States, more frequent in brackish swamps and near the coast, from New England and Lakes Erie and Ontario to Florida and eastern Texas. Its pubescence is wholly a fine, dense tomentum, without any villous hairs, the upper surface of the leaves being nearly or quite glabrous. The flowers are white or rose-color, with or without a crimson base, and the capsule is glabrous or nearly so. The leaves are ovate to lanceolate and acuminate, rounded at base or somewhat heart-shaped, the larger ones usually three-lobed.

H. incanus is very similar, but has sulphur-yellow flowers with a crimson base, and the leaves appear to be mostly ovate-lanceolate. It is found in the swamps of South Carolina and thence to Florida and Alabama, but it has been very rarely collected. Its distinctness from *H. Moscheutos* and from the following species was recognized by Dr. Gray from specimens cultivated last season by Mr. Meehan.

H. lasiocarpus has its leaves nearly equally tomentose on both sides, or rather more coarsely so on the upper surface, and the bracts of the involucre are ciliate. The capsule also is more or less densely hirsute. The leaves are, perhaps, more frequently cordate at base than in *H. Moscheutos*, but the flowers are of the same color. This species ranges from the coast of Georgia to Louisiana and southern Illinois and westward. The extreme western form (var. *occidentalis*, Gray; *H. Californicus*, of Kellogg), of Chihuahua and the swamps bordering the rivers of California, differs merely in the leaves being more uniformly heart-shaped at base, and the capsule pubescent rather than hirsute. This is the form which is represented by Mr. Faxon in our illustration.

Cultural Department.

The Cultivation of Ferns.

FERNS are propagated by the spores or seed and in some varieties by division of the plant itself; while with others, such as many of the Davallias and some other varieties that produce creeping rhizomes, the runners are pegged down and allowed to root, when they can be easily separated from the parent plant. A few others, Aspleniums especially, form small bulbils along and at the end of the fronds, which can be removed and rooted, or can be rooted first and afterwards separated. Those varieties that produce spores freely and can be readily increased in this way, are by far the most valuable to the commercial grower; and as the great bulk of our Ferns are so propagated, I shall speak of this method only. Nearly all the Adiantums, the Pteris, Onychiums, etc., the Ferns most useful for florists' work, can be quite easily propagated in this way. Yet the

Fig. 68.—*Hibiscus lasiocarpus*.—See page 425

work is rather tedious, requiring care and labor, and many disappointments may be experienced. The collection of the spores at the proper time is the first and all-important matter. This can only be done by close and frequent examination of the fronds—the dark color of the sori, and, if closely examined, the bursting of the sporangia or cases containing the spores, will indicate when they are ripe and fit to remove. The fronds

should then be cut and carefully wrapped in smooth wrapping paper, placing the packages in some warm, perfectly dry place. After a week or so the spores will have shed, when they should be sifted clean, and either sown immediately or stored away in tightly corked vials until ready for use. The sooner they are sown the better, however, as those of many varieties soon lose their vitality.

I would recommend spring and autumn as the best times to sow most varieties of Fern spores—those sown in the early fall will make plants for spring and summer sales, while the spring sowing will make stock for fall and winter. Some rapid growing kinds, such as *Pteris tremula*, should be allowed two or three months' less time, otherwise they will become too large for use. The soil used should be about three parts peat or leaf mould, two parts loam and one of sand; this should be sifted fine and then baked, so as to destroy any insects or other seeds that are sure to be in the soil, which, if allowed to grow, would soon crowd out the minute Fern plants.

Shallow pans, six inches square and two inches deep, are preferable to anything else. When the time for sowing arrives, the pans should be prepared by placing a thin layer of broken pots or charcoal in the bottom for drainage. They should then be filled with the prepared soil and the surface pressed firm and even. After thoroughly saturating the soil

close for a week or so after being potted and should never be allowed to become dry. After this first potting I use soil of about two parts peat, three parts loam and one of sand. It is not sifted now, but thoroughly mixed and chopped sufficiently fine for use. A certain portion of peat is preferable, yet when this cannot easily be procured, light fibrous loam and sand will answer very well; when Ferns are wanted for the fronds, it is really better than lighter soil. The fronds will be harder and keep better after being cut.

When once established in thumb pots the Ferns are comparatively safe, and the care is merely a matter of potting on as larger plants are required. Starving for want of a larger pot will seldom kill them; they can be kept a long time, if necessary, in this condition, and then, if shifted on, will start ahead immediately and make the best kind of stock in a very short time.

Established plants should be allowed plenty of fresh air and water when the weather will permit, keeping the houses well

The Charles River at Wellesley.—See page 422.

with water the spores must be lightly dusted over the surface. This one watering before sowing will generally be sufficient until the green scum, denoting the first stage of growth, appears, especially if the pans are placed an inch or so apart in the rows, so as to leave space for watering between. Watering overhead should not be practiced if it can be avoided during the earlier stage of growth. After planting the pans are arranged in a close, well shaded frame. They should be kept close until the pan is covered with the mossy looking growth, the sash being raised only a little every day to permit a change of air. If the weather should be wet and hot, more air should be admitted; fungus and damp must be prevented, if possible, and, as growth advances, more air should be admitted until the time arrives when it will be necessary to close the sash only during the sunny and dry part of the day, and then only partly. The plants must never be allowed to get dry, but should be kept moist, although not too wet. When large enough, my custom is to transplant small clumps into other pans. This is done as a precaution against damp and fungus; when crowded together they will damp off very easily, and, besides this, many plants will be crowded out. The transplanting causes some trouble, but it pays, for, when less crowded, the young Ferns make much better headway. When sufficiently rooted, individual plants should be separated and transplanted again into pans and should be left there until well enough rooted to pot off into thumb pots.

For the first potting the soil should be about the same as that prepared for the seed. The young plants should be kept

shaded during the warm months of the year. In winter much less water and no shading is required. If kept too close and dark, then the condensation of the moisture in the house will cause the foliage to damp.

This applies only to those easily cultivated varieties of Ferns that are grown in large quantities to supply the store trade. Some of the choicer kinds—those that can only be propagated by division, for instance—require far more careful handling.

Adapted from an address at the Florists' Convention, by C. D. BALL, Holmesburg, Pa.

Herbaceous Plants in Frames.

AMONG what are known and grown as hardy herbaceous perennials are many kinds of plants that had better be wintered in cold-frames than trusted to the uncertainties of the weather in open borders. Some of these, for instance *Lobelia fulgens* and *Pentstemon Hartwegi*, are not quite hardy here; others, as *Helleborus niger* and *Cyclamen Europaum*, although hardy enough, can only be enjoyed when grown under cover of houses or frames where we can have their blossoms clean and perfect; and although *Anemone Japonica* and *Verbena venosa* can be mulched with sufficient care to protect them from any injury by frost, it is much less trouble to lift the roots that are needed and save them in a cold-frame. Tritomas and Pampas Grass, too, may be mulched with dry Oak leaves deep enough to exclude any frost from the soil; but here again there is a danger that water may collect around the crowns of the plants and rot

them, and it is safer to lift them with good balls of earth, and keep them in cold-frames or pits. Wallflowers, Hollyhocks and Canterbury Bells are among the commonest flowers in European gardens, but rare in ours because they are not quite hardy. True, with a mulching of dry leaves we may preserve them fairly well, and it sometimes happens that they survive the winter unprotected; but in order to preserve them surely and in good condition the frame must be resorted to, especially in the case of Canterbury Bells. The place in which a plant is growing in the garden often has a great deal to do with its hardiness. Double-flowered Daisies and *Primula Japonica*, for example, growing in open, exposed situations, would probably be winter-killed, whereas if grown in somewhat sheltered places, as in the neighborhood of light-rooting shrubs, they would be hardy enough. But in any case the frame is the safest place for them. In ill-kept gardens and in wild places many plants will survive the winter that would surely perish in prim, well-kept gardens. In neglected gardens, after the glow of summer is over, the plants are disregarded and the weeds allowed to grow; the old stems are not cut over from the Pæonias, Larkspurs, Veronicas or Pentstemons, and when the tree-leaves fall they gather and compact themselves around these plants, and are there retained by the stems broken and bent over them by the winds. This is the best and most natural protection, for the stems arising from the crown of the plant prevent the leaves from becoming a solid, wet mat over the crown in winter. This is the way wild plants are preserved. But in tidily-kept gardens where an accumulation of dead stems and loose tree-leaves is not tolerated, the hardy plants, after being cut over, must be mulched with a dressing of rotted manure, or a thin layer of thatch or sedge, while Santolinas, Acanthuses, scarlet Anemones, Gibraltar Candytuft, *Myosotis dissitiflora*, *Helianthus multiflorus*, Alstræmerias, young Snapdragon, *Stokesia cyanea*, herbaceous Erythrina, *Senecio pulcher*, *Salvia Pitcheri*, Libertias and Zauschneria, and all others of whose perfect hardiness there is any question, should be removed to cold-frames.

These frames should be in a warm, sunny, sheltered part of the garden, and on slightly rising ground, with a south or south-east facing slope, so situated as to drainage that no water can lodge about them or run towards them. For such frames pine plank or hemlock boards are best; spruce rots out in a couple of years. As hemlock warps and slivers, the upper board all around should be pine plank, and under that hemlock will answer. Pine cross-bars drilled along the middle should be used for the sashes to rest on. The three-by-six-foot sash is the best and handiest made, and for this sash the frame should be five feet nine inches wide inside; this allows a solid rest for the sash, and the water can run off without wetting the frame. For ordinary use a cold-frame need not be deep, twenty inches at the back and ten inches in front is a serviceable depth; but even this should not all be above the ground level—twelve inches at the back and six inches in front is high enough above the outside level, and even then the frame should be banked up solid to the top with earth or ashes to keep all snug and warm. The more pitch the frame contains, the better will it shed the water and the warmer will it be in winter.

In filling these frames plant thickly, keeping the tall-growing and evergreen plants towards the back, and the low-growing ones near the front, and use light rather than rich soil. This is merely a winter store-house, and not a place to encourage growth and blossoms, as is the case with frames filled with Pansies, Primroses, Forget-me-nots, Crown Anemones and Violets, which are to grow and bloom during the winter months.

Glen Cove, N. Y.

William Falconer.

Orchid Notes.

Cattleya Bowringiana.—This comparatively new species is now becoming popular, and is likely to prove a great acquisition by filling the gap between the summer blooming Cattleyas and the early Percivaliana or Trianae. In growth and inflorescence it somewhat resembles the old *C. Skinneri*, but the flower, though a little smaller, is much superior in color, while the lip is enriched with a broad band of dark purple. The flowers appear before the growths are quite matured and last three weeks in perfection. It is a free grower, emitting a perfect mass of roots from the peculiar swollen base of the bulb. It should have strong heat and abundance of water during growth, but requires a long rest in a cool house, and should be started as late as possible in the spring, so that the flowers may appear in the early winter months.

The rarest Orchid in flower with us now is *Angraecum caudatum*, a native of Sierra Leone. Though not at all showy, the greenish brown of the flowers, contrasting so beautifully with the snowy whiteness of the lip, and the grotesque arrangement of the long-tailed flowers on the raceme, render it attractive and interesting. It is of erect growth, with thin, drooping leaves, about one foot long; it is growing freely here with the Vandas (which, by the way, we accord more heat than is usually recommended for them), in a basket filled with moss and charcoal. Black thrips will soon disfigure the foliage, unless care is taken to keep it well supplied with water at root and copiously syringed during favorable weather.

Another species from the same locality is in flower, *Angraecum distichum*, one of the smallest of the genus, producing stems about six inches high, with very short, fleshy, deep green, imbricate leaves, from the axils of which the flowers appear. These are very small and pure white, but so numerous that a well grown plant will often be one mass of bloom. Basket culture is best suited to this plant, with a compost of half peat and moss. Pegging down the stems will cause them to break freely at the heel, and so quickly make a bushy plant.

Erides quinquevulnerum.—Though nearly half a century has elapsed since the introduction of this Orchid, it has never, until recently, been plentiful. It grows more freely than many of its congeners and may be depended upon every year to produce its handsome racemes of flowers. It is probably the showiest of the whole genus. The flowers are yellowish white, much speckled with purple, with five large blotches of the same color, which suggests the name. The flowers are also fragrant. A very rare variety, named Farmeri, is entirely devoid of any markings. This plant is from the Philippine Islands, and, consequently, should have heat and water liberally given. To avoid spot, care should be taken that the temperature be not low when the plant is wet.

Kenwood, N. Y.

F. Goldring.

Native Asters as Garden Plants.

IT is only within the last few years that our native Asters have been considered fit subjects for the herbaceous garden, although in England they have been long appreciated, and Michaelmas Daisies, as they are there commonly called, form a part of the stock of the best nurseries. Flowering as they do, very late in the season, it cannot be denied that their decorative value is of the highest order, for they defy cold weather, and are but little injured by the fall rains. Long after their more tender rivals have succumbed to the severe frosts these Asters bloom away as though they rejoiced in the chilly weather, and seem many times more beautiful from the contrast with their brown and frost-bitten neighbors. If we have made a judicious selection of species and varieties, and exercised proper judgment in planting them, the garden will be a source of pleasure for a long time after the more costly, and often less beautiful, exotic summer plants have been cut away.

But the value of these plants does not lie entirely in their sturdiness and their ability to prolong the season of flowers, for they have an intrinsic beauty that compels our attention. Few people question the beauties of the perennial Phloxes as they are now grown, but we have to look back but a few years to find these much-admired plants represented by a few dull purplish-pink and white varieties, with small flowers and narrow petals. In their wild state the flowers of *Phlox paniculata* and *P. maculata* (the parents of our garden varieties) are quite inferior to many of the wild Asters, which undoubtedly are fully as capable of improvements, for, naturally, most of the Asters vary to a surprising degree, and, by careful searching, one may find varieties far superior to the types, and these should be carefully transplanted to the garden. It is best to collect them while in flower, for the best varieties may then be selected, and by transferring them to nursery rows they can be tested before placing them in a permanent position.

Out of the great number of species native to the United States the following are among the most useful: *Aster Nova-Engliæ*, with large, deep blue-purple flowers, when given good cultivation, is a grand plant, growing to the height of six or seven feet, and literally smothered with its showy blossoms. Its variety, *Roseus*, is identical in every way except color, which is a bright rosy pink. *A. laevis* has deep violet flowers, like small Cinerarias, and will grow to the height of five feet. *A. Novi-Belgii* is very variable, both in habit and flowers, the best varieties being very handsome and useful. In color the flowers vary from pure white to deep purple. *A. turbinellus*

is very graceful in habit, with slender, much-branched stems, the large lilac-colored flowers appearing late in the season. Other satisfactory kinds are *A. Shortii*, *A. undulatus*, *A. cordifolius*, *A. patens*, *A. spectabilis*, *A. oblongifolius*, *A. amethystinus*, *A. piarmicoides*, *A. linearifolius*, with its white variety, *A. ericoides*, *A. vimineus*, *A. multiflorus* and *A. dumosus*.

They need about the same treatment as would be given to the perennial Phlox, many of them doing much better when thinned out annually, as they are subject to mildew if grown too thickly, especially if they are somewhat shaded.

Newton Highlands, Mass.

Arthur H. Fewkes.

Mildew on Roses.

HOW best to prevent mildew, or to clear the Roses of this troublesome fungus after it has made its appearance, is a question that often confronts the grower, and particularly at this season of the year, when the sun is still strong at mid-day, and so heating the houses that considerable ventilation is necessary to reduce the temperature. This operation often results in an attack of mildew upon such plants as may have been exposed to a cold draught.

Among the many remedies for mildew, sulphur, in one or another of its many forms, is always found most efficacious, and it is used in a variety of ways. The flour of sulphur has been used for many years for this trouble by dusting it over the mildewed plants. This mode of using sulphur is undoubtedly good at times, but in my experience a better way is this: Take of moderately strong tobacco-water, one gallon; add to it four ounces of sulphur, then boil the mixture for thirty minutes or a little longer. After it has cooled add one part of water to every three parts of the mixture, and syringe the affected plants. In bad cases a second or even a third application may be necessary on successive days. This mixture also tends to keep down green fly, thereby doing double duty.

Another mixture in great favor with some growers is sulphate of lime. A good recipe for this compound is the following: Take of fresh lime, five pounds; of sulphur, five pounds, and of water, six gallons. This should be boiled down to two gallons. After which it should be allowed to settle, and only the clear liquid should be used at the rate of half a pint of the sulphate to an ordinary watering-pot of water. The plants should be syringed with the latter mixture on two or three successive afternoons.

Sulphate of potassium has also been highly recommended, in the proportion of half an ounce of the sulphide to two gallons of water, and applied in the same manner as the preceding mixture. The unpleasant odor of the potassium solution may sometimes prove to be an objection, however.

Still another way of using the ordinary sulphur is by sprinkling or painting it on the pipes, the heat from which causes more or less of the sulphur to pass off into the atmosphere in the form of vapor. This latter method is hardly to be recommended for general use, for, unless used with great discretion, the vapor may be strong enough to bleach the flowers of many of the pink Roses, such as Catherine Mermet, La France and Bon Silene, and in this way may do almost as much harm as the mildew. As the above-mentioned Roses are also affected by tobacco-smoke, the mixture of tobacco-water and sulphur previously mentioned will be found particularly useful in just such cases.

Holmesburg, Pa.

W. H. Taplin.

Very few so-called hardy perennials are sufficiently hardy to endure a northern winter without protection of some kind. This is what should be expected where many kinds we grow come from southern latitudes as well as from the temperate regions of the Old World. Truly herbaceous plants, such as tall Phloxes, Delphiniums, Asters and Helianthus, which die down completely, need the protection of stable manure, since in gardening operations, for the sake of neatness, we must remove from the ground the tops, or refuse, of the plants, which are their natural protection. Others, again, mostly biennials, such as Foxgloves, Sweet Williams and other species of Dianthus, Gaillardias, Geums, Canterbury Bells and Pansies, retain their foliage naturally, and when not removed to frames should be protected by leaves or pine needles to prevent alternate freezing and thawing. The same plan should be adopted with alpine plants, some of which are truly herbaceous, such as *Adonis vernalis* and *Ranunculus* of different kinds, while the majority are evergreen, such as dwarf Phloxes, Veronicas, Cerastiums, Arenarias and Iberis.

There are also many kinds, of which stock is required, which can be taken up and propagated during the winter. All such as we can push into growth and get cuttings from, we

bring into the green-house about February 1st. Others we divide up and pot about March 1st, keeping them in the green-house only long enough to start them, and then place them in frames until the ground is open for planting. The cuttings—Phloxes, Veronicas, *Silene rupestris*, *Salvia Greggii*, *Oenothera Missouriensis*, Monardas, etc.—we put into boxes, partly filled with sand, and covered with a sheet of glass; when rooted we gradually harden them off to be planted later in nursery beds.

Wellesley, Mass.

T. D. Hatfield.

The New Tea Rose, Madame Hoste, is likely to prove the best of the year for cut flowers in winter, under glass, and suitable both for the amateur and the commercial grower. It is a French Rose, and it was sent out for the first time last November, and has, therefore, had no very extensive trial in this country. It plainly possesses all the good qualities of a Rose for winter blooming. It is very large, though opening freely, and has not the least suggestion of coarseness. Its form is of the best, and its color is the only thing to be urged against it. It is neither yellow nor white, but may be described as cream color, deepening to a darker shade towards the centre of the flower. It is so beautiful in every other respect that it must work its way into public favor. The plant is a vigorous grower and a free bloomer, and we may expect it to do well out-of-doors in some parts of the country, since it is well spoken of by English horticulturists who have tried it in that climate.

Philadelphia.

E. L.

Callicarpa purpurea is particularly handsome just now; indeed, it is the only time of the year when it is. The flowers are so very small as not to be worth considering, but following them are berries in clusters of about twenty to thirty each, which in September and October are of a violet-purple color. As every leaf axil has a bunch, and the branches are sometimes two to three feet in length, bending over with the weight of fruit, it is an uncommonly beautiful sight.

The most strikingly beautiful tree, in flower at the present time in the vicinity of Philadelphia, is the Franklinia (*Gordonia pubescens*). It flowers when but a few feet high, commencing in August, and continuing until freezing weather stops it. There are many fine specimens hereabouts; one of the largest, a layer from the original tree in the Bartram garden, is at William De Hart's, Fifty-fourth Street and Woodland Avenue, Philadelphia. It is about twenty feet high, and at the present time (early October), loaded as it is with its large, single, white, Camellia-like flowers, it is an unusual and beautiful sight. The tree can be increased by layering. If good soil be placed about it, and the layer not disturbed for two years, a strong, well-rooted plant results.

Referring to the notes sent you in the spring in regard to the hardiness of the Loblolly Bay (*Gordonia Lasianthus*), I would now add that one of the plants flowered September 15th. May not this be the first instance of its flowering out-of-doors so far north? The blooms, while in general appearance like the better known *G. pubescens*, are but about half the size. The leaves are thick and shining, and not unlike those of *Photinia serrulata*. Nearly all of the twenty-five plants set out last year survived the winter, though injured more or less. Having now become better established, they will doubtless get through the next winter more easily.

The Forest.

The Forest Vegetation of North Mexico.—VIII.

Pinus macrophylla, Engelm., the species which, next to *P. Chihuahuana*, grows at the lowest elevation, is the first tree to claim our attention as we proceed to consider in detail the composition of the forests of the Cordilleras. On all the ranges about the divide we have seen it scattered with the species last mentioned; but in some localities among these ranges it must be more multiplied, since there are several saw-mills in the region. About the base of the mountains on the foot-hills and in the valleys amongst these it is by far the most abundant Pine; whilst over the gravelly plain bordering the foot-hills it spreads out for a few miles to the exclusion of most other trees. Because it makes a larger growth and yields clearer lumber than *P. Chihuahuana*, is more accessible than *P. Arizonica*, and far more common than *P.*

strobiformis, it furnishes nearly all the lumber now cut in the region, the two mills of the vicinity drawing their supply from the plain. In the deeper soil of the plain, where it attains fullest development, its diameter is from one and a half to more than three feet, and its height from forty to seventy feet. Never standing crowded on this plain, its branches are ample. As these begin low on the trunk, the majority of the trees afford but one or two saw-logs. The character of its bark is equally variable with that of *P. Arizona* and *P. ponderosa*, and is undistinguishable from that of these two species, in trees of middle age being dark and more or less furrowed; in mature specimens reddish, smoother and reticulately cracked. Vigorously growing trees in open situations, the symmetrical outline of their broad heads closely filled out with dark green foliage, to which its long leaves (ten or fifteen inches long) give a massive look, its summit distinctively an ogee arch rather than a dome, present an appearance of unusual beauty.

Here on the Cordilleras we seem to have reached the centre of distribution of *Pinus Arizona*, *Engelm.* In this great Mexican forest this species seems to take the place, in respect to abundance, wide distribution and value as a timber tree, held in the forests of the western United States and British Columbia by the closely related *P. ponderosa*, *Dougl.* It ranges through 3,000 feet of elevation from the valleys and cañons of the base to the highest summits. In the deep cañons and fertile valleys it is unsurpassed in size, showing lofty, clean stems three feet in diameter; on the summits it is still a noble tree, and, taking scarcely disputed possession of these, it there forms close forests. Its lumber seems to be prized by the Mexicans equally with that from *P. macrophylla*; but, because the trees are mostly found at a greater elevation, it is far more difficult to secure.

Pinus strobiformis, *Engelm.*, as far as I have observed it, appears to grow scatteringly—a few trees scattered along cañons, a lone specimen here and there on high, cool slopes, or a few on the ledges of summits on the skirts of belts of *P. Arizona*. Such, also, is my recollection of its habit (if we refer to this species, *Engelmann's P. reflexa*) on the mountains of southern Arizona. Nowhere have I yet seen a good grove of this Pine. Its short horizontal branches and tall stems give it an appearance exceptionally slender for a Pine. A diameter greater than two feet, I think, I have never seen exceeded, while its height equals that of any of its companions. As it is one of the White Pines, with characters of bark and leaves closely resembling those of *P. Strobilus*, its lumber, if obtainable in any amount, would doubtless be found of the best class.

Pinus Chihuahuana, *Engelm.*, appeared scattered abundantly over the lower benches and foot-hills, a small, slowly-growing tree, as usual, and here safe from the lumberer's axe.

Only one other Pine, seen by me as yet on the Cordilleras, remains to be described, *Pinus cembroides*, *Zucc.*, the Mexican Nut-Pine, which, like the related species, *P. edulis*, of New Mexico; *P. monophylla*, of Utah, and *P. Parryana*, of Lower California, contributes largely to the sustenance of the Indians by its large oily seeds. For any other purpose this tree is comparatively worthless. Its habitat is the warmest and most arid slopes and ledges with meagre soil, where even *P. Chihuahuana* will seldom crowd upon it. Occupying together with a few shrubs such open situations, its branches near its roots, and forms a rounded top, whose breadth equals its height, which is from fifteen to twenty feet.

C. G. Pringle.

The Forests of Europe.

THE French Ministry of Agriculture has issued some interesting statistics respecting the distribution of forests in Europe. The total area of Europe laid out in forest—exclusive of Turkey, Bulgaria, Bosnia and Herzegovina, omitted in the official statement—is set down at 286,989 million hectares, or about 708,862 million acres; that is, about 18.7 per cent. of the

total area of Europe is forest land. In proportion to its total area, Great Britain and Ireland has, of all countries in Europe, the least extent of forest, amounting to only 4 per cent. of its surface, and, in proportion to the number of its inhabitants, enjoys, by far, the least allotment of forest, amounting to only 0.036 hectare, or 0.089 acre, *i.e.*, considerably less than the tenth of an acre to each inhabitant. The country in Europe next lowest in the forest scale is Denmark, with 4.8 per cent. of forest land, or 0.09 hectare to each inhabitant; that is to say, in Denmark there is an average of between two and three times the extent of forest land to each inhabitant that there is in Great Britain and Ireland. The third of the countries of Europe in the ascending forest scale is Portugal, with 5 per cent. of forest land and 0.11 hectare to each inhabitant, *i.e.*, an average of three times the amount of forest land to each inhabitant of Portugal that is allowed to each inhabitant of the United Kingdom. Holland has 7 per cent. of forest land and 0.05 hectare to each inhabitant, or about one and a half times as much as to each inhabitant of the United Kingdom. The country in Europe possessing most forest is Russia in Europe, with 200,000 million hectares—*i.e.*, 37 per cent. of its whole area and 3.37 hectares to each inhabitant—that is, each inhabitant of Russia in Europe has an average of nearly 94 times the extent of forest land allotted to each inhabitant of the United Kingdom. In its percentage of forest land and the amount of forest to each inhabitant, Sweden, however, stands still higher. With 17,569 million hectares of forest, Sweden has 39 per cent. of its land in forest, and so 3.84 hectares of forest to each of its inhabitants. Norway, with 24 per cent. of its area in forest, allows each of its inhabitants an average of 4.32 hectares of forest, or 120 times as much as is allowed to each inhabitant of the United Kingdom. Hungary has 29 per cent. of its area in forest, or 0.58 hectare of forest to each inhabitant. France possesses 9,888 million hectares of forest, or 17.7 per cent. of its total area, and so allowing 0.25 hectare of forest to each of its inhabitants—nearly seven times as much as is allotted to each inhabitant of the United Kingdom.—*The Garden.*

Correspondence.

The Responsibilities of Florists.

To the Editor of GARDEN AND FOREST:

Sir.—Your recent editorials on the responsibilities of our florists seem to me a word spoken in season. It is true that our florists have done much to improve the taste of the public, but there is still much for them to do. It does not need that one should be of a great age to remember when no taste whatever was shown in the arrangement of our winter flowers. Solid, flat or spherical or conical constructions of wired flowers, massed together without foliage and with no regard to the shape of individual blossoms, were the only bouquets in use. The first novelty in the right direction came from Boston in the shape of bunches of long-stemmed flowers, chiefly Roses, which, even in other cities, were called "Boston bouquets." Eagerly accepted by the public, they soon ousted the formal bouquet and their influence was quickly perceptible in arrangements of all other kinds. To-day, as you say, one can buy flowers in no other part of the world so beautifully arranged as we can buy them here, except, perhaps, in Paris; and even Paris is behind us in the matter of variety. The Germans arrange their growing plants more tastefully than we do, but of the artistic possibilities of cut flowers they have duller perceptions, and the practice of wiring is far more extensively practiced than in America.

Nevertheless, it is only in a few of the best shops in the larger cities that taste is displayed. Our best work is very good, but our worst—and there is still a great deal of it—is undeniably bad. A long list might be made of "floral designs" recently produced and viewed with satisfaction by their authors and the public, which would seem too bad to be true in a community which calls itself civilized. Not long ago I saw carried through the streets of New York on the wagon of a florist a horse about half life-size, composed of white Immortelles, with the saddle and harness of colored flowers and a flowing mane and tail of Pampas Grass. I am told that at the funeral of an expressman in Boston there was, not long ago, displayed a large trunk of white flowers bearing, in red, the poetic legend "C. O. D." I know of a florist in Chicago who wrought for a funeral a white pillow in the centre of which was a purple horse-shoe, and who could not be brought to perceive the grotesqueness of thus placing the symbol which means "Good luck to you." And here is a quotation from a Boston paper describing a device which was sent to the bier of General Sheridan and called "one of the most beautiful" of its kind:

"The piece is nearly six feet high, six feet long and four feet in width, and represents 'Gates Ajar.' In the centre are two large pillars, from which are hung two gates. Joining the pillars is an arch, having in the centre a cross and crown. Suspended from the arch is a pure white dove, and on the top of each pillar is a large star. Looking through the open gate and picket fence is a representation of the Garden of Eden, in which flowers, roses and ferns abound in artistic profusion. On the right corner is a beautiful bouquet of roses tied with satin ribbon. Across the front is the inscription, 'Light lie the earth on thee.' Some 4,000 Asters and a large number of Crimson King Carnations, Chrysanthemums and Roses were used in making the piece, which will be sent as the gift of a number of United States Senators."

So long as pretentious abominations of this kind are created how can we really congratulate ourselves on our taste? And who could look at the use that was made of flowers last Decoration Day, and feel that, as a people, we had a proper sense either of the beauty of flowers or of the meaning of the word decoration in its general sense?

I know that it must be extremely difficult to do really well on public occasions like this, when a hundred hands must help to dispose of a myriad gifts of all possible varieties and degrees of beauty. But the fact is not that we did not do really well, but that we did so very badly, that, in New York, at least, as I can say from careful observation, few examples could be found where a spark of good taste was apparent. Here not the florist, but the public at large, was perhaps responsible; and doubtless in the case of many of our worst "set pieces," like the expressman's trunk, the purchaser gives the idea, and the florist is simply charged with its execution. But in many cases the florist may be to blame; and in all, I believe that a word of discouragement and better advice from the florist would change the current of the purchaser's wishes. It is hard to say, in this as in all other matters, just how the law of supply and demand affects the results we see. But, as one of the public, I wish to emphasize your statement that if florists will consistently point in the right direction the public will surely follow. If it likes bad things, it is because it has not seen enough good ones to know the difference. The taste of our people is not naturally bad; it may be uncultivated. Show them excellence, and they will admire, and when they next see ugliness they will recognize it for what it is. Anything really lovely is sure to find a welcome even from the casual passer in the street. The most tastefully arranged florists' windows in New York are those which people stop to notice—not the windows which contain the greatest amount of novelties or the most striking flowers. An example of this fact struck me forcibly last winter. Many windows, filled with a profusion of costly blossoms, tastelessly heaped together, were unremarked, while there was a constant crowd around one which showed nothing but a mass of Ferns and other green, and in the centre a large plain blue vase, in which stood half a dozen branches of pink-flowered Japanese Plum.

Marion, Massachusetts.

M. G. Van Rensselaer.

The Exhibition of the Architectural League.

To the Editor of GARDEN AND FOREST:

Sir.—The Architectural League of New York announces that its fourth annual exhibition will be held in December. In connection therewith a competition for the gold and silver medals of the League will be opened to all architects and students under twenty-five years of age residing in this country. A similar competition, organized last year, dealt with the designing of "A Clock Tower on a Village Green," and called forth some excellent drawings. The problem chosen for this year is "The Tomb of a Celebrated Architect." Admirably adapted to reveal the artistic skill and taste of those who will compete, as distinguished from their mere "originality" in impulse and audacity in execution, this problem is, moreover, one which, in the results we may anticipate on the exhibition wall, should be of particular interest to landscape architects and the public at large.

As has often been pointed out in GARDEN AND FOREST, our cemeteries are, in theory, one of our chief titles to respect as landscape gardeners and lovers of beauty; but, in concrete fact, they often fall below the ideal at which they aim. In no point is success less often achieved than in the erection of large and costly structures—vaults above ground, shafts, architectural monuments or sculptured figures—commemorative of an individual or a family. Year by year such conspicuous memorials arise in growing numbers in the burial-grounds near our large towns. In Greenwood, for example, there are very many, some of home manufacture, and others imported from Italian workshops. But, varying though they do between

the extremes of severity and ornateness, they seldom wear an aspect which even moderately satisfies the eye or corresponds with the sentiment which should prevail in such a cemetery. When they are not too gloomy to seem like monuments of the Christian dead, they are too frivolous; and even if the general effect is nearly right, the inartistic execution apparent upon a near view destroys much of their claims to approval. Some of the façades to vaults excavated in a hill-side look like ice-houses or coal cellars, others like the homes of Egyptian mummies. Some of the family tombs imitate little heathen temples, others suggest kiosks, and others soda water fountains. When sculptured figures are used, the hand of the stone-cutter rather than the artist is most frequently revealed; and the plainer shafts are too commonly devoid of the only qualities which could make them works of art—beauty of proportion and grace of profile. They might be taken as relics of some long past stone-age rather than what a community can secure which has architects to do its bidding. I do not doubt that there are other good large monuments in Greenwood, but the only ones I can recall at this moment are the graceful Gothic tomb which commemorates those members of the Brown family who perished years ago in the wreck of the "Arctic," and the Stewart tomb near the main entrance, the sculptured decorations of which were designed by Mr. St. Gaudens in his earlier years. This, which is a façade merely, the vault being excavated in the side of a bank, hits the right medium, I think, between over-sombreness and frivolity; the sentiment of its decoration is Christian, and in execution it is a work of art. It is dignified but not pretentious, beautiful but not obtrusive.

If the sculptor or the architect, in the true meaning of the words, were more often employed in similar work our cemeteries might speak with honor to the living as well as the dead. The coming exhibition of the Architectural League ought to mark a noteworthy step in this direction. Of course, as the competitors will be students and not practiced masters, the designs it shows will not prove—they can merely indicate—what good work we might secure in the way of mortuary monuments. Yet there are many men of skill and taste even among our novices in architecture, and doubtless some of the coming designs will be intrinsically worthy of much praise. The programme wisely guards against exceptional extravagance in design by prescribing within comparatively narrow limits the size of the tomb and of the lot upon which it shall stand; and although a tomb appropriate to a great architect may not give us with precision a type which would serve for ordinary mortals, yet its peculiarities may very likely be confined to its decorative motives alone. Therefore I venture to bespeak for the exhibition the notice of all who are concerned in the improvement of our cemeteries, and who believe that the way to improve them is to bring in the artist where the artisan has ruled too long.

New York.

George Cumming.

Japanese Iris from Seed.

To the Editor of GARDEN AND FOREST:

Sir.—In GARDEN AND FOREST, No. 34, page 402, Mr. A. W. Fewkes has an important article on raising Japanese Irises from seed. My experience differs from his in regard to the fertility of flowers which have not been artificially fertilized. Last year I bloomed ten plants for the first time. The plants were not large; one bore but a single spike of bloom, and many flowers were cut. From the seed which set and ripened from insect fertilization four hundred plants were raised this summer. During the present year some flowers were artificially hybridized; but those not so treated have, in almost every instance, developed full seed-pods. My culture does not differ essentially from Mr. Fewkes', so that no reason for the discrepancy of experience can be suggested other than a possible cause in the difference of locality.

Boston.

Robert T. Jackson.

Notes.

The delicate and fragrant flowers of *Clematis crispa* are still opening in considerable abundance. The vine has been in bloom five months.

Mr. S. H. Vines has been appointed Professor of Botany at the University of Oxford in place of Professor J. B. Balfour, who was recently called to Edinburgh.

Owing to the reduced state of the funds at command of the California State Board of Forestry, the offices of Botanist, Engineer and Special Agent have been declared vacant from the 1st of November.

According to Professor N. S. Shaler, the value of the artificial manures manufactured in this country from mineral phosphates already amounts annually to \$30,000,000, and the industry is but at its beginning.

The oldest Rose bush of which there is any authentic record is growing against the old church at Heltersheim, in Germany. Eight hundred years ago, it is said, Bishop Hepilo caused a trellis to be erected to support it. The main stem is thicker than a man's body.

The extraordinary force exerted by growing Fungi was well shown the other day in a New Hampshire village. It was noticed that a cone about seven inches in diameter was rising in the middle of an asphalt walk. Beneath it a Mushroom was discovered, which had cracked and raised a solid stretch of asphalt two inches in thickness.

Five new experimental stations for the study of Sorghum and its manipulation are being organized by the Agricultural Department in Washington. One of them will be in New Jersey, one in Louisiana and three in Kansas. The appropriation for the work exceeds by \$100,000 that of any previous year. Dr. Neale, of the Agricultural Station at New Brunswick, N. J., has spent the past summer studying European methods of sugar manufacture.

Vilmorin & Co. recently exhibited before the *Société Nationale d'Horticulture de France* the fourteen varieties of *Gladiolus Gandavensis*, which long experience shows to be the latest blooming of the innumerable varieties grown in the neighborhood of Paris. They are named: Abricoté, Atlas, Béatrix, Coquette, Docteur Fontan, Gallia, Médicis, Etna, Mimos, Rosini, E. Souchet, Eugene Scribe, Sceptre de Flore and Ambroise Verschaffelt.

Two of the three huge and ancient Oaks which have stood for centuries near the "Bush Mill," in the neighborhood of Frankfort-on-the-Oder, have recently perished through the effects of storms. The last to fall measured over twenty-one feet in circumference. Its top was blown off by the wind, and although the trunk was still sound, the Forestry authorities decreed that it should be felled. The one which remains has a circumference of twenty-three feet.

The large Bald Cypress (*Taxodium distichum*) in the old Bartram Garden, West Philadelphia, is still alive, though apparently near its end, as but a few live branches exist near its top. A recent measurement of this tree, at four feet from the ground, gave twenty-seven feet as its circumference. At a distance of about twenty feet from the trunk, along the ground, appear numerous "knees," which always excite curiosity in those who have not seen the trees in their native places.

The Countess of Kenmare has planted a large collection of Australian trees in her beautiful grounds near Killarney, in Ireland. As a proof of the mildness of the climate in this region, it may be noted that a *Dracana australis* flowered this season near Cork, after having been grown in the open air for seven years, and reached a height of fifteen feet. The head of bloom lasted in all its beauty for two months, and measured three and one-half feet in height by three feet in breadth.

The bad taste sometimes displayed in this country in the conception and arrangement of floral designs is quite as often and as conspicuously shown in other lands. For example, among the set pieces recently exhibited at a horticultural show in Cologne, there was one which represented a life-size baby in swaddling clothes, and another in which a swan was figured by means of the detached petals of Water Lilies. Beyond this last, misplaced ingenuity could hardly go; for, to dismember the flowers employed, is, of course, to deprive a result of all title even to the name of a floral arrangement.

The fruit growers of Sutter and Yuba Counties, California, after twenty-five years' experience, do not speak favorably of irrigation. At a recent meeting of the Sutter Horticultural Society many of them bore testimony against the practice. Instead of the use of water, they urged the use of cultivators and pulverizers in orchard and vineyard, which was regarded as better, cheaper, healthier, and certain to produce richer, sweeter and better flavored fruit than artificial moisture. The fruit grower, like the wheat grower, must plan to meet average conditions. He cannot plan for extraordinary seasons, or, in other words, he cannot create costly irrigation works that may not be needed once in twenty years. Besides, the driest hills and vales will not produce a bountiful crop of fruits with the most abundant artificial water supply every year; kind nature will have her rest occasionally.

Professor Maynard, of the Massachusetts Agriculture College, finds the Worden by far the best Grape to plant for profit in New England. It is equally hardy, productive, and of as good quality as the Concord and more than a week earlier. We find it a decided improvement on the Concord in quality. Professor Maynard pronounces the Brackman more vinous in quality and nearer the perfect Grape than any variety except Iona. It ripens with the Delaware, but is not quite as sugary. In foliage it resembles the Clinton and it has not mildewed. The fruit of the Iona is of excellent quality, but it is tender, with foliage liable to mildew and fruit to rot. If subsequent experience confirms the last two seasons' trial of the Brackman, which so closely resembles it in fruit, this Grape will prove a valuable addition to New England vineyards.

One of the finest gardens in India is that of the Nizam of Hyderabad in the Dekkan. The horticultural skill of the country, developed by centuries of experience and lavish expense, has been taxed to the utmost to produce the labyrinths of shade, the brilliancy of color and the clouds of perfume which all Orientals love. Thick plantations and shrubberies are combined with gorgeous designs, composed of bright-colored flowers, which, we may believe, Oriental taste has made more beautiful than those we commonly see in western countries; and a large use is also made of small plants in pots. An idea of the magnitude of the garden and the expense of maintaining it may be gathered from the statement that it contains six million potted plants, each of which is watered every day. A natural arrangement seems to have been adopted for the most part, as a recent writer in *Harper's Magazine* speaks of "miniature lakes . . . laughing nooks, now a bit of jungle and now a broad and beautiful open space, where the distant view was enchanting."

The *Times-Democrat*, New Orleans, states, on the authority of our consul at San Salvador, that the fibre of the Banana is one of the valuable products of the soil which is now largely suffered to go to waste. This fibre, which may be divided into threads of silken fineness, extends the length of the body of the tree, which grows without a branch from ten to fifteen feet high, and has a circumference at the base of two and a half to three feet. In Central America, the fibre, with no preparation except drying, is used for shoe strings, lariats and cords for all purposes. In its twelve months of existence, the Banana trees bear only one bunch of fruit, but from two to four or ten trees spring from the roots of the one that has fallen. At home the bunch of Bananas is worth fifteen cents, and the dead tree nothing, though, if the supply were not inexhaustible, the latter would be worth ten times the value of the fruit to a cordage factory, paper-mill or coffee-sack maker. The Banana leaf, with stems of the toughest and finest threads, is from two and a half to three feet wide, and ten to fifteen feet long, and serves the native women of San Salvador as an umbrella in the rainy season, a carpet on which to sit, and a bed on which to rest.

Bulletin No. 39, from the Department of Entomology of Michigan Agricultural College, contains an admirable account of the summer's experiments with insecticides. It has been demonstrated that it pays to spray Apple-trees with London purple to protect the fruit from the codling moth. The spraying should begin as soon as the blossoms have fallen. If the poison is applied earlier it endangers bees and other insects which help to distribute the pollen, and it may do harm to the honey. One application is enough unless a heavy rain follows, when it is well to spray a second time. One pound of the purple to 100 gallons of water is strong enough mixture, and the second application should be weaker. Several good pumps and spraying nozzles are described. It is found that the same poison applied two or three times is of advantage against the curculio. There is a probability that lime-water will accomplish the same result, as has been explained in this journal. If so, this will be preferable to the arsenites, as it does no damage to the leaves, and it is better to avoid the use of poisons when we can. It has been found that air-slacked lime, to which has been added some crude carbolic acid, will repel the attacks of curculio. Professor Cook substituted plaster for lime, and found it more convenient, as it did not fly so badly as the lighter lime. He used one pint of the crude acid to 100 pounds of plaster, and with this both Cherry and Plum trees were dusted from a tall step-ladder. The mixture should be applied just as the calyx is falling from the fruit, or just as the curculio begins to lay its eggs. The Plums and Cherries on the trees thus treated were practically free from worms, and the application did no harm to the trees. The same remedy would probably prove successful against the curculio on Pears and Apples, but it would hardly prevail against the codling moth.

Do Not Spare the Axe.

WE have often alluded, in these columns, to the importance of thinning plantations, and more than once called attention to the causes which prevent people, especially those who profess a deep and sincere fondness for trees, from cutting them, when cutting is essential, if the beauty and health of other and more important trees are to be preserved. It is not easy, indeed it is practically impossible, to lay down rules which should govern the thinning of plantations made and maintained for ornament. Thinning is an operation requiring judgment, and judgment in such matters can only come with long experience, and a real knowledge of trees, their characters and requirements. Each case, where it is a question of removing a tree from an ornamental plantation, must be studied on its individual merits, and no rule can be formulated to cover a number of cases. We speak now merely of trees with reference to their effect upon other trees, and not of trees as forming a part or parts of a landscape. The cutting of trees for the purpose of improving a landscape effect or for purposes of mere convenience, as where a tree casts too dense a shade over a dwelling house or other building, presents different problems, which we shall not undertake to consider at this time. What we want to insist upon is, that it is impossible to have fine trees unless light and air and space are provided for them, and that the right amount of these can only be determined by persons familiar with trees and their requirements from the hour of planting. If a number of trees are huddled together no one of them can ever develop into a handsome and symmetrical specimen, and not only are those trees which have been allowed to grow in youth with sufficient space about them the most beautiful, but such trees are the most vigorous in old age and the longest lived. Some trees require more space than others for their best development from an ornamental point of view. Some are most beautiful when they stand entirely alone as isolated specimens; there are others which grow together into harmonious masses of foliage. A Beech is a far more beautiful object when its lower branches sweep the ground, than when it exposes a tall, bare trunk, the result of overcrowding and insufficient light. A White Oak standing alone upon a lawn is val-

uable in proportion as it has retained its lower branches, and as these rest upon the turf, while the naked trunk of a White Oak in the midst of a large plantation is one of the most beautiful objects which our forests afford. A single White Pine or a group of these trees, without lower branches and with tall and naked shafts, are handsome and natural objects anywhere, while the moment the lower branches of a Spruce or a Fir perish, the beauty of these trees, as ornaments for the lawn, is destroyed forever. No one, therefore, will be able to thin a plantation with real success unless he is familiar with the appearance of the trees with which he is to deal at all stages of their growth and has a clear idea of the effects they are intended to produce as they approach maturity.

There are other cases where cutting down trees requires neither profound knowledge or great judgment, as when a really fine tree—or what might in time, with a little care, develop into a really fine tree—is ruined by the too close proximity of a neighbor possessing neither beauty nor value. How frequent such cases are, any one who looks at trees with the least critical eyes must see. Certainly there are few fine specimen trees to be seen in this country in comparison with the immense number which have been planted during the last fifty years. This is due to the fact that people are unwilling to use the axe. Either they refrain from cutting altogether, or they delay cutting so long, that the damage is done, and the tree which ought to have grown into a noble, widespreading specimen, is left stunted and misshapen. Examples of this neglect of the requirements essential to the growth of a fine tree can be seen on every hand. It is not necessary to look beyond the parks and squares of this city to find abundant evidences that the axe is not often used freely or judiciously. Of the thousands of trees planted on our public grounds, but few have been granted the opportunity for free development, and but few have attained the dignity of stature and expression which they might have reached. The popular clamor is against cutting down a single tree, and year after year starved and often half-dead specimens, destitute themselves of all beauty, present or prospective, are allowed to encroach more and more upon others, which only need a little space and a little light to become objects of the highest civic pride to future generations of New Yorkers.

The lesson which every man who controls trees, whether they be few or many, great or small, should learn, is that whenever he sees a really beautiful, well developed and symmetrical tree, its perfection is due to the fact that it has had, either by accident or by design, sufficient room in which to grow and develop its beauty. This lesson cannot be repeated too often, and until its force is fully appreciated, and until a tree out of place is considered a weed, and destroyed as promptly as other weeds should be destroyed, fine trees will continue to be as rare as they are at present. That they are rare, any of our readers who will examine with critical eyes at this season of the year, when the leaves have fallen, or are falling, their own trees or those which grow upon any public highway or pleasure ground in their neighborhood, will be able to see for themselves. This is the season of the year to study trees with the view of removing all those which are injuring their more valuable neighbors.

Piazas.

NOTHING is more characteristic of American country houses, as contrasted with those of other northern lands, than their large covered piazas. These have been developed in answer to as distinct and imperative a national need as ever determined the genesis of an architectural feature. Our early colonial ancestors did without piazas, for their habits of living and their architectural schemes were alike imported from England and Holland, and amid a strenuous people occupied with sterner problems than how to live most agreeably, it was naturally some time before that gradual modification of habits

which is inevitably brought about at last by new climatic influences, could express itself in architectural language. No colonial house had anything that resembled a piazza. If we find one attached to such a house to-day, it is an addition of later date—as is the case with the well-known Longfellow house in Cambridge.

But the introduction of the classic fashion in architecture meant the erection of porticoes, and the addition which they made to comfort has never again been dispensed with. When classic forms were abandoned in favor of what has been dubbed our "vernacular" style of architecture—when little temples gave way to plain, square, box-like houses with gabled roofs—the portico vanished, but its place was taken by a modification of the veranda which had long been in use in all southern lands. We speak of the course of things in our Northern States; at the South, where Spanish influence was felt, verandas and balconies seem to have been used from the earliest times.

When we say a "vernacular" style of architecture, we mean one which has been the unaffected outcome of universal needs and desires; and, therefore, whatever its defects from an artistic point of view, must have a large measure of practical fitness to recommend it. Many factors of such a style must persevere if progress in art is to mean more beauty and more fitness too; and, in fact, widely as we have departed from the plain, box-like house in recent years, our best new country houses are, in many respects, developed from them, and most notably so as regards the constant presence of the piazza. Considerations of sentiment and art excuse and make good its absence to the owner of an old colonial house; but when a new house is desired it is a clearly recognized necessity, even though some colonial scheme may be closely followed in other respects. Only in very rare cases do we see piazzas dispensed with by an owner who cares more for the odd pleasure of copying with exactness an inappropriate foreign model than for building himself a really comfortable home.

Certainly no really comfortable country home can exist in our land without a piazza. Even on our most northerly borders the heat of our summer atmosphere and the strength of our sunshine make exercise in the open air, to the extent to which it is practiced in England, for example, a sheer impossibility. Nor, for similar reasons, can we sit with comfort on the lawns of England or the uncovered terraces of France, or in the arbors, placed at some distance from the house, which are so characteristic of German villas. We must have a wide and open yet covered space, closely connected with our living rooms, where we can pass our hours of rest and many of our hours of occupation too. How necessary it is we read in the fact that, when well arranged, the piazza always becomes the very focus of domestic life and social intercourse—as central a feature in summer as the parlor fire-side is in winter.

But it is hardly needful to-day to affirm that an American country house without a piazza in it is in every sense a mistake and a failure—that it palpably lacks fitness and therefore must lack true beauty in the eyes of intelligent observers. It is more needful to protest against the excessive use of piazzas than to urge their erection. When their value was first fully appreciated it was believed that they could not be too freely used. A house of any importance most frequently had three if not all of its sides encircled by them, and their breadth was often as excessive as their length. To-day a reaction has begun to set in, and most fortunately. Piazzas on all sides of a house mean that all the rooms are darkened and that direct sunshine can nowhere enter the lower floor. This consideration is important even when a house is meant merely for summer use; and it is all-important when winter as well as summer comfort must be secured. Again, experience will always show that with very extensive piazzas only certain portions are commonly used, and that other por-

tions might be removed and never missed. And, finally, as one of the most difficult of current architectural problems is so to treat the piazza that it will seem an integral part of the house instead of a mere attached shed, it will be understood that the larger it is, the harder becomes the task. If we look at our best recent houses, we find that the main piazza is confined to one side, or, placed on a corner, partly encircles two sides; and there can be few cases in which more than this is needful.

But for this to suffice the piazza must not be considered as a mere adjunct to an interior which may be planned without regard to it. Success in its arrangement will depend upon choice of exposure and outlook, but also upon the way in which it is connected with the interior. If a piazza does not command the best view or has not sufficient light, or, on the other hand, admits the sun too freely, it will be a perpetual exasperation to its owner; while if it is not easily accessible from the most commonly frequented rooms, it will not fulfill its whole purpose. And, again, a want of thought in placing it may needlessly injure the rooms, excluding light and sun where they are most to be desired. In short, the piazza must be considered from the very outset as an integral portion of the house, and at every step in the planning a careful compromise must be made between its claims and those of the interior. Of course no general rules for its arrangement can be laid down. In some cases there may be but one possible position in which a piazza can exist; in others the advantages of a certain exposure or a particularly charming point of view may be of determining weight; while in others again there will be a much wider latitude for choice. The only rule is to consider all claims together from the very beginning, and to know clearly which ones, by reason of the habits and tastes of the owners, ought to be most fully met, if compromise of any conspicuous kind is necessary. Naturally the claims of the piazza should have more weight when a house is meant only for summer use, than when it will be lived in all the year round.

Entrance to the Temples at Nikko, Japan.

THE illustration on page 439, drawn from a photograph, shows the first or outer gate leading to the memorial temples at Nikko. They were erected in honor of Eyeyasu, the founder of that Tokugawa dynasty, which is more commonly called the dynasty of the "Tykoons," and contain his tomb.

The avenue which leads from Utzunomia to Nikko—a distance of twenty miles—is lined on either side by a double row of tall and stately *Cryptomerias*. Their branches, joining overhead, form a compact arch over the whole distance, and they have stood for 300 years—since the temples were erected by Eyemitz, the grandson of Eyeyasu. At the end of this avenue, as our picture shows, rises a low terrace, upon which more of the great Conifers stand, forming a superb frame, with their great, furrowed, stately trunks and masses of dark green foliage, for the low but richly colored buildings. The simplicity of the terrace—its steps and balustrade, seems excessive, perhaps, to western taste, in view of the rich adornment of the area to which they admit. But it is a good expression of the belief which to a Japanese is one of the first canons of good taste—that simpler things should lead up to more elaborate ones, and that the place where display should not be made is that which is most conspicuously presented to the public eye. From this standpoint the design of the terrace is excellent, and the great stone lanterns at either side of the steps give just the needed decorative accent.

The temples at Nikko are considered the finest in Japan and their site is famous for its natural charms. "He who has not seen Nikko," says a popular aphorism, "does not know how to use the word beautiful."

The Pines in October.

IT is past the middle of October, and several light frosts have cut the more tender herbage, but we still find a good many charming flowers and plants. The Asters and some of the Golden-rods are beautiful now, but the greatest number were in the height of their beauty in September. The New England Aster is still beautiful, and its flowers are more brightly colored in the Pines than in most other localities. Occasionally we meet groups with great masses of rose-colored corymbs, and others of deep violet and purple. This fine Aster takes kindly to cultivation, and graces our garden with its bloom long after Dahlias and other fall flowers are blackened with frost. These garden clumps are from seven to eight feet in height, with many-branched stems, each stem and branch terminated with a dense corymb of bloom. The stems are sufficiently strong to stand erect without stakes. The brilliancy and sweetness of the flowers attract hosts of butterflies, among them the beautiful Painted Lady (*Pyra-meis cardui*) and the Red Admiral (*P. Atalanta*).

The Silky Aster (*A. concolor*) is another handsome species, which grows in the more dry barrens. It has slender, wand-like stems from two to three feet in height, which sway gracefully among the grasses, displaying its showy raceme of flowers. The rays are violet-purple, and very numerous, and the stems are crowded with grayish silky leaves. *A. spectabilis* is just now in its prime, and is one of our handsomest Asters. It is a low-growing plant, not more than two feet high, and, when planted about a group of New England Asters, its deep blue rays make a striking picture. Another pretty, low-growing species is *A. nemoralis*. This grows in the damp barrens, and has lilac-purple rays and numerous small leaves with revolute margins. Many other species grow here which are worthy of notice and cultivation.

The Golden-rods have been unusually fine this autumn, and some are still in bloom. One of the most beautiful is *Solidago sempervirens*, with smooth, fleshy leaves and spreading panicles of deep golden blossoms. Its habitat is the salt marshes, but it grows here—some twenty-five miles inland—in many places. No doubt the seed has been brought in salt hay, which is fed to stock and often used for mulching. *S. elliptica* is another beautiful species growing in the damp barrens, now brilliant with bloom. The leaves are smooth and shining, and the flowers are in dense, spreading racemes. Numerous other species grace the roadsides and neglected fields, here as elsewhere, making the "closing out" the most splendid display of the year.

The large Bur-Marigold (*Bidens chrysanthemoides*) is still in bloom among the Sedges in the wet barrens. It is showy and handsome, the deep golden-yellow rays being an inch or more in length. Near by, the pretty Ladies' Tresses (*Spiranthes cernua*) are scattered among the grasses. This little Orchid has pure white, waxy flowers spirally twisted around the stem, and deliciously fragrant. *S. graminea* and *S. gracilis* are also here, each with their several varieties. The species seem to run together, and are a puzzling group to the botanist. Possibly this mixing is due to the work of insects which visit the flowers, and carry the pollen masses to other plants, fertilizing one species with another.

The False Rocket (*Cleome pungens*) is established among our native plants. A stout, much-branched specimen, with long spikes of handsome purple flowers, was growing where white sand had drifted around it. It was much more vigorous than some others found in damp soil. The leaves and stems had lost none of their mephitic odor in this poor soil, and therefore it was not a desirable addition to our wild bouquet. The Swamp Maples and Sour Gum or Tupelo, and the Liquidambar, or Sweet Gum, together with the lower-growing trees and shrubs, have a brilliancy of color which cannot be excelled in any part of our country; but, unfortunately, we lack the roll of hill and

valley, the foundation of cliff and mountain-side for the proper display of this grand picture.

Many trees and shrubs are now beautiful with their ripening fruits. The dark foliage of the Hollies is in fine contrast with its scarlet fruit. The Black Alder (*Ilex verticillata*) is conspicuous with its deep red, clustered fruit, and the fragrant Wax Myrtle (*Myrica cerifera*) is full of its grayish, waxy berries. Inkberry and Sumach, Ampelopsis and Smilax, all help, with fruits of varied form and color, the beauty of the dying leaves, and make our woods and fields more beautiful, if possible, in October, than they have been at any other season of the year.

Vineland, N. J.

Mary Treat.

Foreign Correspondence.

London Letter.

TO-DAY'S meeting of the Royal Horticultural Society was in strong contrast to that a fortnight ago, when the hall glowed with the colors of a thousand Dahlias. The hall was very dull, a sharp frost a week ago having promptly put an end to the Dahlia season once more. The reign of the Dahlia continued but three weeks this year, and if all our seasons were so cold, sunless and rainy as the present we should abandon the cultivation of this flower altogether. The great feature of the meeting to-day was a marvelous exhibition of Ferns, chiefly stove and green-house kinds, sent by Mr. H. B. May, of Edmonton, one of the chief Fern-growers for Covent Garden market. The collection numbered hundreds of plants, representing the very finest Ferns in cultivation, and included not only such kinds as are grown specially for market, but a host of others, many of them rare, that could not be seen elsewhere than in the largest collections. Mr. May has for years devoted himself specially to these plants, and has succeeded in raising many varieties of the highest excellence, among them being such beautiful kinds as *Adiantum Reginae*, *Pteris Crelica Mayi*, *P. serrulata cristata compacta*, *P. tremula flaccida*, *P. tremula elegans*, *P. tremula grandiceps*, all of which he grows largely for market, and which, no doubt, are known now in American gardens. The five named first have received the highest awards of merit from the Society. Passing over a crowd of species and varieties that would be uninteresting to the general cultivator, I was anxious to know the kinds Mr. May grows most extensively for Covent Garden, and as these may be useful to some readers, I append the list. For cutting—that is, for cut fronds gathered in convenient sized bunches—the following are most largely used: *Adiantum cuneatum*, the common Maidenhair Fern grown by thousands; *A. Williamsi*, with the fronds powdered with gold; *A. elegans*, a form of *A. cuneatum*, with longer and larger fronds and smaller pinnæ. The list of the kinds grown for sale in pots includes, besides the foregoing, *A. scutum*; *A. Reginae*, very dwarf, with young fronds coppery red; *Pteris Crelica albo-lineata*, *P. Crelica Mayi*, *P. serrulata major*, a robust growing variety; *P. serrulata cristata compacta*; *P. argyrea*, with silvery marked fronds. *P. tremula*, and its several varieties, all favorites in the market; *Cyrtomium falcatum*, capital as a room Fern, as it withstands dust so well; *Phlebodium aureum*, *Lomaria gibba* (when small), *Doryopteris palmata*, *Onychium Japonicum* (also for cutting) and *Asplenium bulbiferum* (and its varieties), which is the most useful of all the Aspleniums for market. These comprise most of the kinds grown specially for Covent Garden, and this list has been compiled from years of experience, and is rarely added to, as few new Ferns possess the requisite qualities for market, which, first of all, must be elegant, then robust and easily and quickly grown into plants of salable size, and, moreover, must be easily propagated. They must also "carry" well—that is, they must not be liable to injury from rough usage in getting them to the market and by the treatment they receive there.

Among the few plants and flowers which won first-class certificates was one Orchid, the beautiful little *Cattleya porphyrites*, supposed to be a natural hybrid, but between which species I cannot say. It is a small grower, with slender pseudo-bulbs from six to eight inches high, carrying a pair of leaves. The flowers are about four inches across, with rather narrow, purplish rose sepals and a beautifully formed lip with rounded lobe of an intense maroon crimson. It is an exquisite little Orchid, and Baron Schroeder, who exhibited it, prizes it highly. Messrs. Veitch, of Chelsea, showed, in their choice group, a new hybrid Pitcher Plant named *Nepenthes Dicksoniana*, in honor of the late Professor Dickson, of the Edinburgh Botanic Garden. It is a cross between *N. Veitchii*, which has large, handsomely-shaped pitchers with broad grooved rims, and, in color, a pale green, and *N. Rafflesiana*, the well-known species, with its large pitchers boldly blotched with blood-red on a green ground. The hybrid partakes of the characters of both parents, but is handsomer in shape than either, as large as *N. Veitchii*, and more beautifully marked than any form of *N. Rafflesiana*. It is, moreover, a very strong grower, as most hybrid *Nepenthes* are, and forms pitchers freely, which is a great recommendation. A new Maidenhair Fern named *Adiantum Waltoni diffusum*, was worthily certificated, as it is a most elegant Fern and a robust grower. The original *A. Waltoni* reminds one of a tall growing form of *A. cuneatum*, with small, deeply cut pinnæ. The variety *Diffusum* differs in its larger fronds and more spreading habit. Both this and the type originated with Mr. Walton.

An early Chrysanthemum named Elsie was exhibited by the well-known grower, Mr. Stevens, of Putney. It is a large flower with narrow, reflexed florets, very full and of a delicate straw color (some call it primrose), just such a tint as every one admires. The certificate was voted unanimously, a good criterion of its merit. Another new Canna, so bold and handsome in foliage, so brilliant in flower, that it quite captivated many of the committee, also won a certificate, but it was not so fine as some that Messrs. Cannell have shown previously. Its name is Ulrich Brunner, and it has brilliant scarlet flowers with green foliage. It was shown by Messrs. Veitch. A group of double flowered Begonias from Messrs. Cannell was next passed upon, and two were singled out as worthy of certificates. One was Mrs. Stuart, with flowers of a rich, clear yellow; the other General Chubet, of a beautiful rose cherry. Both have a dwarf, sturdy growth, the blossoms being of enormous size, very double, and resembling double Hollyhocks more than Begonias.

The other exhibits worthy of notice included a new Rose all the way from Elsinore, in Denmark. The blooms were much damaged, and several were of the opinion that the variety was identical with La France; but as the blooms came through Mr. W. Paul, of Waltham Cross, who, of course, knows Roses as well as any one, the committee reserved their opinion until they see good blooms early in the season next year. It was named Hybrid Perpetual Denmark. Messrs. Veitch had in their group some noteworthy plants, such as a basketful of admirably grown and flowered specimens of *Bouvardia President Cleveland*, which is considered to be the finest of all the scarlet *Bouvardias*. Its color is very brilliant, and the flowers and trusses are both large. The same firm also showed *Amasonia calycina* (*A. punicea*), a new stove plant with scarlet bracts, and long, pale yellow flowers that are produced in continuous succession for several weeks in autumn and winter; *Amaryllis Autumn Beauty*, a hybrid from *A. reticulata*, with large, pink flowers always produced in autumn when no other *Amaryllis* is in bloom, and *Begonia John Heal*, a charming little winter flowering *Begonia*, obtained by crossing *B. Socotrana* and *B. insignis*. It produces an abundance of rosy carmine flowers, which, in contrast to the large, pale green foliage, is very beautiful. It is justly looked upon as a first-rate winter flowering plant.

Baron Schroeder's gardener, Mr. Ballantine, showed cut blooms of two choice Orchids, *Laelia Dominicana* and *Laelia Novelty*. The first is a cross between *Cattleya Dowiana* and *C. Exoniensis*, and it is strange that this mingling of two *Cattleyas* should make the hybrid a *Laelia*, but so it is. It has the large, bold flowers of *C. Dowiana*, lilac-rose sepals, and a broad lip of the richest crimson purple, not a trace of the characteristic golden tint of *C. Dowiana* being present. This is one of the rarest of all hybrid Orchids, and very few plants of it are in existence. *C. Novelty* is a hybrid between *Cattleya marginata* and *L. elegans*. It is a good deal like *C. porphyrites*, but the tube of the lip is pure white, which is a strong contrast to the crimson lobe. Some plants of *Adiantum Farleyense*, said to have been raised from spores, were shown by Mr. Goldby, of Brierfield, who states that he sowed the spores on February 23d last year, and the sporlings appeared soon after. If this statement is correct, it tends to disprove the theory that this beautiful Maidenhair Fern is a hybrid, and never produces fertile spores.

London, October 9th.

W. Goldring.

New or Little Known Plants.

A White-Flowered *Cattleya Gigas*.

THIS very interesting novelty, of which an illustration of the only plant now known appears upon page 437 of the present issue, was collected by Mr. Francisco Timanotiny for Messrs. Siebrecht & Wadley, in Medellin, United States of Colombia, during the autumn of 1885, and has been successfully flowered by them during the past summer in their Orchid establishment at New Rochelle, near this city. The sepals and petals of the flower are pure white, while the large, full lip is white, delicately shaded with rose, but preserving the two faint yellow eyes characteristic of the species, from which this variety does not otherwise differ.

The plant has been added to Mr. F. L. Ames' rich collection of Orchids, where it is now making a vigorous and satisfactory growth.

Cultural Department.

The Propagation of Conifers.

MANY propagators of Conifers put in cuttings and do their grafting between early August and October, but while some succeed, many more fail. My experience is that the very changeable weather of our late summer and early autumn renders this work most difficult then, because greater attention is needed to keep the degree of temperature and moisture uniform than it is later in the season. Many Conifers, it is true, will root at any season, but it is nearly impossible to persuade others to root during the hot weather. In the winter season the plants seem to have stored up all the material ready for use in making a new growth, so that they are in better condition to form callus and roots than at any other time. There is also less evaporation under glass in winter than there is in hot weather, and by artificial means we can control the conditions of heat and moisture more easily. In fact, the more steady the cold weather in winter, the better is the chance of success in propagating hard-wood plants.

A green-house is essential for the propagation of evergreens in winter as far north as Boston. The cuttings can be put in an ordinary propagating bed, in pots or in boxes. For large lots, I prefer shallow boxes, and for smaller quantities pots are chosen, since they can be more conveniently removed without disturbing the roots. In any case, good drainage must be secured with potsherds or coarse gravel covered with moss or peat to keep the sand from sifting through. The cuttings should be collected, if possible, on mild days, and when not frozen. If not used at once, they can be kept in damp moss, in a cool place, for a week or more without injury. If the cuttings must be gathered in freezing weather they should be buried in damp moss for several hours before they are used. The cutting should be made with a heel, using a sharp knife, and it should be from two to four inches long in most Evergreens. As soon as made, the cut-

tings should be put in so closely as to touch each other, and a good watering should be given to settle the sand well around them. They should then be placed on benches in a cool house, where the temperature does not rise above 45° at night, or ten to fifteen degrees higher during the day. In sunny weather a slight syringing once or twice a day will be needful, and they should be shaded if necessary. They should be kept at this low temperature for one or two months, or until well calloused, when the temperature can be increased by 10°, and if a slight bottom heat can then be given it will hasten the rooting. About the middle of April they will, in most cases, be well rooted, and as soon as the weather is settled they can be hardened off in frames with a slight protection, and if planted out in frames by the middle of May, they will be established by autumn, and will need no protection until the ground begins to freeze. Choice varieties, as soon as they are rooted, should be transplanted into boxes of

Sciadopitys also roots well, though slowly. All varieties of the Box can be treated in the same way as Conifers. *Ilex glabra* and *I. Aquifolium* root well from cuttings of the current year's growth, and the former can be put in at any time from November till February; but *I. opaca* should be put in early in November and kept in a close frame until well calloused, which requires from two to three months. Cuttings should be taken from a fruiting plant if the berries are an object, and the same can be said of all plants of the Holly family.

While most Conifers, except Pines, can be propagated reasonably well from cuttings, stronger plants can be obtained by grafting, but many gardeners who do not hesitate to graft the most tender plants seem afraid to make the trial with Conifers. With few exceptions they are easier to graft than many hard-wood plants, although more time is required to complete the union. In grafting, the first consideration is the proper selection and preparation of stocks. These should

Fig. 69.—A White-flowered *Cattleya Gigas*.—See page 436

light soil, and grown during the summer under glass. They should be wintered in cold pits, and transplanted into beds the following spring. Among the Conifers I have successfully treated in this way are *Thuja occidentalis* and its varieties, *Chamaecyparis (Retinospora) obtusa*, *C. pisifera*, *C. plumosa* and its varieties. Such Junipers as the Irish, Swedish, Douglas' Golden and other varieties of common Juniper, *J. Japonica* and some varieties of *J. Virginiana*; *Picea nigra humila*, *P. excelsa Gregoriana*, *P. pungens*, *P. Omorika* and *Abies concolor*.

I find the best time to put in cuttings of most evergreens is from the middle of November to the middle of January. I have tried several hundred cuttings of *Picea pungens*, giving them every possible care, and yet lost all but two in a hundred of them, while of those put in in January I have saved fully one-half. In taking cuttings of *Picea* I find the smallest wood the best. I have not been successful in propagating varieties of the common Hemlock from cuttings, although cuttings of Japanese Hemlock (*Tsuga Sieboldii*) root well. The Ginkgo roots readily from hard or soft cuttings.

be potted, if possible, in spring, and plunged in a sheltered situation where they can be watered during the summer; and at the approach of freezing weather, they should be put in a cool cellar or pit where they can be kept until needed. They should be taken into the house two or three weeks before the time of grafting, so that the sap may be well started. Where the stocks have not been prepared in spring they can be potted in October or November and put in a cool green-house, where they should be syringed daily in fine weather and kept in a temperature of not less than 50° at night, with a little bottom heat, if possible. As soon as the new roots reach the side of the pots the grafting may begin.

But besides having the stocks in good condition, it is a matter of importance to know what kinds to select for the different species and varieties. For all Firs, seedlings of *Abies pectinata* or *A. balsamea* make the best stocks. For the Spruces, the Norway is the best and most easily obtained, although the White Spruce makes good stocks. It is, however, more difficult to procure. The common Hemlock

is the best stock for *Tsuga Sieboldii* and for varieties of *T. Canadensis*. For the Retinosporas, Lawson's Cypress and other species of *Chamaecyparis*, together with *Libocedrus decurrens*, the common Arbor Vitæ, and the White Swamp Cedar, make good stocks, but plants of this class do better on stocks of the common form of *Chamaecyparis pisifera*. This last roots readily from cuttings and makes good stock in two years. The common Red Cedar is the proper stock for all species and varieties of the Juniper except *J. occidentalis*. I find no better stocks than White Pine for all Pines of the five-leaved section, while for the two-leaved Pines, the Scotch Pine is generally used, although the Red Pine would be better if it could be easily procured. Some three-leaved Pines, like *P. rigida*, *P. Taeda* and *P. ponderosa*, do quite as well, so far as I have observed, on this same stock. Varieties of the common and Japanese Yews graft well on seedlings of the common Yew. Thuyas do well when grafted on stock of common Arbor Vitæ. The Western Larch, the Japanese Larch and varieties of the European Larch graft readily on this species, but I have not been successful with *Pseudolarix Kämpferi* on the same stock, nor on *Larix leptolepis*. Sometimes it will make good growths for a year, but, with me, it gradually dies out.

I usually begin to graft Conifers late in December, and can graft with success, if need be, until the first of March. After that time they are more difficult to manage. The very best results are secured from December to February. The mode of grafting depends much upon the time of year and other conditions, but I have found the simplest method the best, although other ways may be tried for experiment's sake. The side or veneer method is most easily learned, and has this advantage over cleft grafting—namely, that if the graft does not take at the first operation, the stock is not destroyed for the season, but the operation can be repeated on another side or a little lower down. In making this graft a smooth place should be selected on the stock, and a slight downward cut should be made with a thin-bladed knife a few inches from the base of the plant, cutting entirely through the bark, but, if possible, not into the wood. Then the blade is inserted two or three inches above, cutting a thin slice off the bark down to the cross cut below. A similar slice is cut from the scion and the end of the scion is cut with a slight angle on the opposite side to fit into the lip of the stock. The two are then closed together, care being taken that the cambium layers come in contact with each other. They should then be bound firmly with strands of bass ruffa, or other soft tying material. The grafted plants are then laid on their sides in a close frame which has been previously prepared by putting in a few inches of sand or moss. No wax is needed at this season. For the first few weeks the frames must be kept close, and the plants need a slight daily syringing in fine weather. When they show signs of knitting together, which will be usually in two or three weeks, a little air may be given, and after the house is closed, the sashes may be raised for several hours, and finally air may be given them all night. The grafts will need looking over occasionally to see that no ties are cutting through the stock or scion. If they are, loosen and retie. Union will be effected easily in from five to eight weeks, although in some species a longer time is needed. As soon as the grafts are established they should be taken from the frames; and the tops of the stocks should be shortened. They should be set on benches in the green-house and treated as other plants. Do not cut the stock back closely until the following spring; this is especially necessary in the case of Pines and Spruces; many plants are lost by heading back too early. As soon as the weather is settled in May, the plants can be taken from the green-house and plunged in beds. If the roots are matted they should be carefully separated and spread out, for when once the roots of Conifers are pot-bound, unless they are separated, they will continue growing in a contracted way, and many valuable trees have been lost from this cause. When evergreens have been grafted and laid on their sides in damp sphagnum, and covered several inches, they require much less care, and a few moments' neglect will not be felt as it would otherwise. A few years ago, for experiment's sake, I grafted 100 stocks of *Picea pungens* and laid them on a side bench which was covered with six inches of sphagnum. I then covered the grafted plants about one-third of the way up. These were syringed lightly once or twice a day in sunny weather, and the temperature of the house was kept at about 50° at night, the moss being on a slate bench over the pipes which were kept at an even temperature of 65°. The result was ninety-two strong plants without the aid of a double frame. Some nurserymen seeing the experiment have tried the same with equal success.

I was first led to this method by accident. I had a corner filled with moss, and late one evening buried a few plants that had been grafted. Then I forgot them until I had occasion to remove the moss, and found that the plants had taken well. This led to further trial, which has proved of considerable value to me.

The Vegetable Garden.

ALL tender crops, as Snap and Lima Beans, Egg Plants, Peppers and the like, have been destroyed by frost, and are now cleared away and the ground they occupied manured and dug. But many crops are not yet gathered, and it often is inconvenient to manure and dig a piece of ground lately occupied by a tender crop—like melons, for example—till the hardier crops, as Parsnips, growing in contiguous plats, are also removed. Asparagus tops have been cut, cleared away and burned, and we are now manuring and digging the ground. We plant our Asparagus deep enough to allow us to plow or dig over the crowns without touching them. The stumps of the stems which are left in the ground cannot now be removed, but in April and before Asparagus cutting begins they can be pulled out with the greatest ease. Were they left in the ground in spring they would be in the way of the knife used in cutting the crop for use. Asparagus can be planted now as well as in spring, on the level and only a few inches deep; but if planted in trenches eighteen inches deep, as the large market growers do, then planting had better be deferred till early spring.

It is now time to attend to the lifting, topping and storing for winter of the root crops. Pull up the Beets, and save the nice, well shaped, tender ones. Large, coarse, old roots are not worth saving for culinary use. In cutting off the leaves do not cut quite close to the bulb, else it will bleed, and never cut off the end or tap root. Lay them on the ground in heaps of one or a few barrells, and cover them with tops or straw enough to exclude frost, with a shutter over that to protect them from rain, and leave them here for a week or ten days to sweat. Then bring them into the pit, cellar or other winter quarters; do not store them for the winter in large bulk, else they will rot. In order to keep them plump and fresh pack them in open, narrow, well ventilated bins in the vegetable house, and use a good deal of ordinarily moist sandy soil thrown in among them. Treat Carrots in the same way, only the leaves can be cut close to the roots and they may be stored in large bulk if desired. Although Carrots keep fresher when packed in sand or earth, this is not at all necessary. Parsnips may be treated as Carrots. But as Parsnips lose much of their flavor when kept out of the earth, we pack them in sandy soil and in this way retain their good taste. Salsify, Scorzonera and Skirret should be treated like Beets. Do not crop them close. Treat Turnips in about the same way as Carrots. Much difficulty is often experienced in keeping Jerusalem Artichokes from rotting in winter, but with proper care they keep very well. The tubers mature slowly and should not be lifted till late in the season. Then store them on the ground in very small bulk, covering them with some straw and a little earth, or a shutter over the straw to keep the tubers dry. At the end of a week or two store them in the root-house in small bins and with plenty of earth or sand among them. Horseradish is another root that should now be lifted and stored in sand or earth. If not kept in this way it wilts and loses much of its pungency. In preparing it for storing, cut off the tops, also the thong roots, which are not large enough for culinary purposes, and save enough of these long, straight, fleshy roots for sets for next year. Instead of having sets two or three inches long, have them eight or ten inches long.

In lifting and storing root crops, be particular not to remove them at once into their winter quarters unless they are exceptionally congenial. Never store away roots that are wet or in any way decayed. See that the root-house is dry overhead and at the bottom, that it is moderately dark and well ventilated, and that it can be kept uniformly cool, say about 34° to 40°. Never store roots of any kind in large bulk.

Turnips, Carrots and Potatoes, of which we usually have the largest bulk, may be successfully wintered in out-door pits. We always store hundreds of barrels of Carrots in this way: the pits are five feet wide, six inches deep and of a length to contain the crop. The Carrots are heaped up three feet high along the middle. Some thatch is spread over the roots, then a coating, some eight to twelve inches thick, of earth, is placed over the straw. Drain tiles, as ventilators, rise from the roof of these pits every five feet.

It is not well to lift root crops, except Potatoes, before sharp frost occurs, and even then we should not cover them up

thickly till near the time when settled wintry weather sets in.

Many root crops—Parsnips, Salsify, Scorzonera, Artichokes and Horseradish, for example—are perfectly hardy with us, and keep better and retain their quality better when left in the ground and lifted and used as required. But this is impracticable. We may leave a part of each crop in the ground till early spring, if so desired, but as it is advisable to have the ground completely cleared of summer crops, manured and plowed or dug in fall, this work could not well be done if some of each kind of roots were left growing in the ground till spring.

Roots of Sea Kale, Dandelions, Sorrel and Chicory, for winter forcing, should be lifted now and stored in sand in the root house for use as desired. In topping them, we are careful never to cut into the crown, as it is the leaf and not the root that is used. As the winter advances we keep up a succession of these vegetables, planting the roots thickly in soap

should be avoided at all times during the winter, and especially with Papa Gontier and Niphetos. Both of these Roses are very susceptible to excessive watering, and will soon show its effects by an unhealthy appearance and the loss of a large portion of their foliage.

Another trouble the Rose-grower has to contend with at this season, or has to contend with to a greater extent at this season than during the summer months, is the disease known as "black spot," or "black mildew," an insidious and most persistent enemy to healthy Rose growth, and though well known in appearance, Rose-growers seem unable to entirely prevent its ravages, especially among the Hybrid Teas. Various modes of treatment have been adopted for the purpose of preventing or curing "black spot," and with various degrees of success, the most approved method at present being that of keeping the affected plants rather dry at the root, and at the same time giving them a slight increase in temperature. This

Entrance to the Temples at Nikko, Japan.—See page 434.

boxes placed in the Mushroom house or other quarters, where a temperature of 60° or over is maintained. And when they start to grow, in order to have the tops well bleached and tender, we invert other boxes over those in which the roots are growing.

William Falconer.

Glen Cove, N. Y.

Roses.—A close watch should be kept at this time of the year for the first appearance of red spider on the Roses, because, when taken in time, the spider may be exterminated before much injury has been done. Unless very carefully fired during the changeable weather of the autumn, the houses on some occasions may get too warm at night, and when this occurs the foliage of the Roses becomes weakened and an easy prey to the spider. Thorough syringing, with a good pressure of water, is the most effectual method of dealing with red spider, and by using a good head of water the stream can be used to much greater advantage on the foliage without giving an undue amount at the root, which latter condition

seems a reasonable treatment, from the fact that the spot almost invariably follows excessive watering, when the latter is coupled with a close, moist atmosphere. It is also well to remove the affected leaves as much as is possible without actually stripping the plants, as it is most likely that the growth of the fungus is encouraged and spread about by the decayed leaves falling on the ground. In fact, cleanliness will be found to pay in the Rose-house at all times of the year. This disease has given most trouble among the Hybrid Tea Roses, such as La France, Bennett, American Beauty, and others of similar character, and from the preference it has shown for this class of Roses, it would seem as if there was some special defect in their constitution, which laid them open to its attacks. Either this is true or else the prevalent mode of growing them is defective. Possibly the deciduous habit of the Hybrid Perpetuals may have something to do with the peculiarities of the Hybrid Teas, though the latter class is usually understood to do better when treated

as Teas, than when grown by the methods adapted to Hybrid Perpetuals.

Philadelphia, Pa.

W.

Schizostylis coccinea.—We are now enjoying the flowers of this beautiful South African plant. It belongs to the Iris family, and is commonly known as Crimson Flag or Kaffir Lily. It always blooms in fall, especially from October till December. During the winter months it requires the protection of a cool green-house or warm frame, but throughout the summer months out-door treatment. Rich, moist soil and a sheltered, slightly shaded place suits it best, and it may be grown in pots or planted out in summer, and lifted and potted in September. In order to have it in its greatest luxuriance, however, it should be planted out permanently in a frame from which frost is excluded at all times. The flowers are crimson, one and a half to two inches across, and closely arranged on spikes after the fashion of some Gladioli. Propagation is easily effected by means of division in spring or early summer.

Helianthus Maximiliani.—This is the finest hardy perennial Sunflower now in bloom. It grows from seven to ten feet high, and just now (in late October) its long, wand-like stems are terminated for two to three feet of their length with bright golden-yellow flowers closely set to the stems. The whole plant is rough-hispid; the leaves are alternate, scabrous, lanceolate, acute. The species is indigenous to the "Prairies and plains west of the Mississippi, and from the Saskatchewan to Texas." It spreads a good deal at the root, but not nearly to the extent that most other perennial species do. There is a current idea that it is not quite hardy, but we have never known it to show any signs of being tender. We find that growing it for several successive years in one place in the garden debilitates it, no matter how much manure we give it. It should be transplanted to fresh ground every second or third year if it is to continue at its best estate.

G. C.

Notes From the Arnold Arboretum.

A SEVERE and sudden frost in the middle of September, following six weeks in which the rainfall was almost without a parallel in amount in eastern New England, and during which the sun was rarely seen, destroyed the foliage on many plants, and has greatly impaired the beauty of many others, which, ordinarily, at this season of the year, are more beautiful than at any other. Fruits, too, have ripened badly, and many shrubs, native and foreign, are almost destitute of berries, which are often more attractive than the flowers preceding them. It is probable, moreover, that the damage inflicted by the unusual wetness of the season will not be fully felt until next year. Unripened wood, and the wood of comparatively few plants is thoroughly ripened, means that many plants will be killed back during the winter, and that those which bloom upon this year's growth, even if it is not killed, will not produce many flowers next spring and summer. Plants, therefore, of doubtful hardiness, should be protected this winter with unusual care; and even those which have shown themselves perfectly hardy for years will be all the better for a little protection during the cold weather, in view of the unusual climatic conditions of the past season. There are some plants in the collection, however, which are very beautiful now, and it is perhaps well to mention them, for if a plant assumes a brilliant autumn coloring this year, it may be depended upon to do so under the most unfavorable conditions.

The foliage of the common Barberry (*B. vulgaris*), of European origin, loses its leaves late, and after a very slight change of color. This plant, naturalized in North America, has not changed its character in this particular with its change of home, and in New England still lacks autumnal brilliancy of leaf. But the common Barberry is a plant of wide geographical distribution. There are growing in the Arboretum specimens of Manchurian and of Japanese origin. The former, which in some gardens is known as *B. Amurensis*, is now bright with orange and scarlet, while the Japanese plant is still more brilliant and more beautiful. The fruit of this last is smaller, and borne in shorter racemes than upon the European plants. For its foliage, if for no other reason, the Japanese Barberry should be better known in our gardens. Still more brilliant is the autumn coloring of *Berberis emarginata*, a Siberian plant, closely related to the common Barberry, and perhaps to be considered as a mere geographical variety of it. This is certainly one of the most desirable of shrubs, considered with reference to the autumnal coloring of the foliage. *Berberis Thunbergii* is very beautiful, however, at this season of the year, and the large and conspicuous fruit, solitary, or more rarely umbellate, remains unshriveled upon the branches

until the appearance of the new leaves in spring. The growing popularity of this plant is certainly well merited. *Berberis Chinensis*, the most graceful of all the Barberries in this collection, is still perfectly green. Later it will be clothed in brilliant hues. There is a difference, however, in the autumn coloring of different individuals of this group, the plants which originated in the mountains of northern China being the most valuable in this respect. The fruit of this species is unsurpassed in size and brilliancy of coloring and in the length of the long, graceful racemes, which now fairly weigh down the slender, pendulous branches. The pretty little Himalayan *Berberis concinna* has turned brilliantly, too, to orange and scarlet, and so has our only eastern American representative of the genus, *Berberis Canadensis*, a rather rare Alleghany plant.

Many of the North American *Ericaceæ* are now striking and beautiful objects. None are more beautiful than the common high-bush Blueberry, *Vaccinium corymbosum*, which, when well grown, is sometimes eight or ten feet high, and a stout, thick, wide spreading bush. It is impossible to describe the splendor of the scarlets with which, at this time, its leaves are tinged. They are fairly dazzling. This plant is beautiful when in flower; its fruit is handsome, abundant and of excellent quality, and among North American shrubs there is none more brilliant in late October. It is easily transplanted from its native swamps and hillsides to the garden, where it thrives in good soil and grows with more rapidity than most plants of its class. More than other Blueberries, too, it shows a tendency to vary in the size, shape and quality of its fruit. Any attempt to improve the Blueberry by selection, with the view of adding it to the list of cultivated fruits, should naturally begin with this species. Simply as an ornamental garden plant, it deserves a place in every garden, and it is surprising that gardeners have so long and so generally neglected it. Two Huckleberries, *Gaylussacia frondosa* and *G. dumosa*, are very brilliant just now, and, like all the *Vaccinia*, should find a place in gardens where attention is paid to planting for autumn effects of color. And very brilliant, too, is the Sourwood, *Oxydendrum arboreum*, which is hardly surpassed in color at this season of the year by any American tree. Here it is scarcely more than a tall bush, but in the forests, which cover the sides of the southern Alleghanies, it becomes a fair-sized tree, rivaling the Flowering Dogwood and the Tupelo in its scarlet leaves, the effect of which is increased by the long compound racemes of yellow fruit hanging from the extremities of all the branches. This tree is often planted and greatly esteemed in Europe, where it has been known for a century at least. Here it is little known by gardeners and rarely seen in gardens.

The leaves of *Rhododendron Vaseyi*, recently figured in this journal, have now turned to a deep, dark crimson, a character which will increase the value of this beautiful and interesting addition to our garden flora. The wood, in spite of the wet season, seems thoroughly ripened, and the plants are well set with flower buds.

Cornus florida has, as usual, turned to a deep, rich scarlet, and *Cornus sanguinea* is hardly less attractive, with its broad leaves now the so-called old gold color, with the margins of a deep scarlet. The habit of this plant is exceptionally good when it is given room for the free development of all its spreading branches; and the bright color of its bark makes it an agreeable object in winter after the leaves have fallen.

Viburnum acerifolium, one of the commonest of the native species in hilly and in northern regions, shows some pink in the prevailing scarlet of the autumn tints of its leaves, which are not surpassed in brilliancy by those of any other *Viburnum*. This plant has a neat and compact habit of growth and handsome black fruit, which make a pleasant contrast with the foliage. The foliage of *Viburnum pubescens*, which is another rather small growing native species, worthy of a place in every garden, turns to a deep and very rich dark purple, which is quite unlike that of any other shrub in the collection. It contrasts admirably with some of the species, like the last, with brighter foliage.

The Witch Hazel, the latest of all our shrubs to flower, is now in full bloom, the pretty yellow flowers being partly hidden by the ample leaves, which have turned to orange, and will fall before the petals. This autumn color of the leaves of this American plant does not appear in those of its Japanese congener (*Hamamelis Japonica*), which shrivel and fall while still green. *Fothergilla alnifolia* has brilliant golden leaves just now, while those of the Japanese *Photinia villosa*, figured in an early issue of this journal, are now of a brilliant scarlet. A better acquaintance only confirms the value of this plant for garden decoration.

Some plants are valuable because their foliage is able to resist frost, and to keep green and bright very late in the autumn. The common Barberry is a conspicuous example of this sort; others are *Akebia quinata*, a handsome Japanese climbing plant, related to the Barberries, and the well-known Japan Honeysuckle. The leaves of most of the Japanese plants in cultivation turn in the autumn to the same colors which their American congeners assume, but in the case of these two plants, both of which, in more temperate climates, retain their foliage until spring, the leaves remain green until killed by severe freezing; and this is true of nearly all European shrubs and of most European trees, *Acer platanoides*, the Norway Maple, being the only one of the common European trees which assumes here anything like brilliant autumn tints of color.

Few shrubs are in flower. Flowers may still be found, however, in considerable profusion upon *Daphne Cneorum*, a plant which remains in bloom almost continuously during the season. Few shrubs produce more attractive or more fragrant flowers, and were it only a little more hardy and a little less slow to propagate, this *Daphne* would be one of the most desirable of all low under-shrubs for the garden-border or for the rockery.

The Japanese Honeysuckle, or that variety which is very generally known in American gardens as *Lonicera Hallii*, is still sparingly covered with its deliciously fragrant white flowers, which turn yellow in fading, and which nothing but the most severe freezing ever entirely destroys.

The latest growths of the Texan *Clematis coccinea* are still covered with the bright and handsome scarlet, bell-shaped flowers, peculiar to this species—a remarkable fact in the case of a plant of such southern origin, which would hardly be expected to be hardy in the New England climate. The capacity to bloom late adds very considerably to the really great ornamental value of this pretty plant.

Flowers may be found still upon the Japanese Rose (*Rosa rugosa*), especially upon plants of the white-flowered variety; but this, perhaps, is accidental. This fact, too, increases the value of this plant, which seems to possess all the qualities which make a plant valuable in ornamental gardening. It is hardy, and it grows rapidly; the handsome and fragrant flowers, varying on different individuals from deep dark red to the purest white, are produced almost continuously from early spring to late autumn. The foliage is unequalled among Roses in luxuriance and in the depth and brilliancy of its dark green, which in autumn turns to intense shades of crimson and orange. The large and abundant fruit is not less showy than the flowers, while, more than all other Roses, it is free from the attacks of injurious insects. Care must be taken, however, to select plants of good varieties. Very inferior ones are often sold in nurseries, hybrids probably of this species and *Rosa cinamomea*, which are not worth planting.

There is a variety with double or semi-double flowers, which shows traces of the blood of some other species, but it is not worth a place in the garden. The best of a large number of varieties in this collection are one with very dark red, single flowers, a seedling raised by Mr. Dawson, and the pure white single-flowered variety.

October 21st.

The Forest.

The Forest Vegetation of North Mexico.—IX.

Juniperus pachyphlœa, Torr., one of the noblest of American Junipers, not rarely attaining a diameter of three or four feet, and a height of fifty, admirable for its symmetrical and compact habit and large reddish brown fruits, ranging through the mountains of southern Arizona, New Mexico and Texas, is at home on all the ranges about the divide and throughout the Cordilleras forest as far south, probably, as the state of Jalisco. From the cañons of the mountains about Chihuahua to the highest summits of the Cordilleras, it ranges through nearly 5,000 feet of elevation. Attaining its fullest development in rich and watered cañons, it nevertheless mounts in smaller specimens to high and dry slopes and rocky ledges.

On the driest crests of ridges near the summits, where the soil was little more than disintegrated porphyry or granite, grew *Juniperus tetragona*, Schlecht., branching at the base and sending up several bushy stems to the height of ten or twenty feet oftener than taking the form of a tree.

Even nearer the summits, but standing with other trees

in better soil, I found the other Juniper, *L. occidentalis*, var. *conjungens*, previously mentioned as common on the summits of the dry ranges of the centre of the plateau. With Junipers so common and widely distributed over Mexico, it would seem that the supply of railroad ties need not be imported from far northern swamps at a cost of a dollar apiece.

Pseudotsuga Douglasii, Carr., the Douglas Spruce, as might be expected, was found in high cañons with a northern aspect, not exceeding here *Pinus Arizonica* in its dimensions, and with it *Abies concolor*, showing a diameter somewhat less.

Above these on the cool talus of cliffs were occasional belts of Aspen, *Populus tremuloides*, so familiar to northern eyes, here a slender tree only a few inches in diameter.

Quercus grisea, Leibm.—Nine-tenths of the Oaks of these mountains would seem to be of this species. It mingles with the long-leaved Pines on the plains at the base, it predominates over the Pines and all other trees on the foot-hills and benches, and it straggles after the Pines up the slopes to the very summits. Only in the cañons that are deepest and wettest does it yield place to other species.

In these *Quercus reticulata*, HBK., reaches proportions gratifying to behold to one who, searching the Santa Rita mountains of Arizona for a specimen for the American Museum, saw but a single specimen worthy to be called a tree, that growing by a spring far up towards the summits, and only got down by great labor. All through these wet cañons and far up their sides, if it can have the shade of cliffs, this Oak habitually makes a tree of good size. Mounting the ridges, however, it diminishes in size in direct ratio to the amount of water in the soil, till on their arid crests it assumes the form of low bushes, and forms thickets of chapparal. It is my impression (I would like to see the test made), that the wood of this species most nearly of all Mexican Oaks approaches in quality that of our White Oak, *Q. alba*, and, if seasoned with due care, might be employed in carriage work.

Quercus hypoleuca, Engelm., also flourishing in the cañons, but spreading more commonly than the last over the cooler benches and slopes, makes a larger tree, one not rarely two or three feet in diameter. This is one of the most attractive of Oaks, in open situations showing a symmetrical outline with close evergreen foliage, deep green and glossy above, white or fulvous-tomentose beneath.

Quercus fulva, Leibm., appeared less frequent than the above species, and was only seen on the lower benches and ridges in warm exposures. It is but a small tree in its best development, seldom more than a foot in diameter and thirty in height. With its great leathery leaves it presents a striking appearance.

Arbutus Xalapensis, HBK., was found sparsely scattered over these mountains in a great variety of situations, and was seen on the ranges as far eastward as Chihuahua. Its diameter of one or two feet is disproportionate to its height. Of stooping habit, throwing out long tortuous branches without regard to symmetry, it assumes grotesque forms; and with its white bark, on the branches mostly smooth, its evergreen leaves and pink flowers, succeeded by scarlet berries, it is a tree of unique appearance.

Another *Madroña*, *Arbutus petiolaris*, HBK. (?) was not scarce, though confined entirely to the northern verge of ridges, and cool, dry soil formed of disintegrating porphyry. This tree is rather smaller than the last, but resembles it in appearance, except that its entire bark is smooth and reddish, and its leaves broader, serrate and pubescent.

There was a surprising paucity of shrubbery in these forests among the Oaks. I call to mind only *Ceanothus Fendleri*, Gray, *C. azureus*, Desf., var. (?) *parrifolius*, Watson, on rocky hills, *Arctostaphylos pungens*, HBK., in dry situations with *Pinus cembroides*, and *Spiræa discolor*, Pursh, var. *dumosa*, Watson, about the ledges of the summits.

Correspondence.

The Mountain Laurel.

To the Editor of GARDEN AND FOREST :

Sir.—I have a desire to introduce the Mountain Laurel on a place about fifty miles south of the White Mountains, in New Hampshire, but have been told by skilled gardeners and others who have given particular attention to the subject, that it is practically impossible to transplant, or to propagate it from cuttings. I have planted the seed (a year ago), but, as yet, with no results. If any of your readers could give any hints or information on this subject, it would be much appreciated.

A. L. Dow.

Brooklyn, N. Y., October 15th, 1888.

[The Mountain Laurel (*Kalmia latifolia*) is easily transplanted from the woods. Young plants, not more than eight to twelve inches high, should be selected for this purpose. They should be carefully dug during the latter part of September or in October, and if they are to be planted at a considerable distance from the place where they have grown, the roots should be enveloped at once in sphagnum moss and the plants packed in boxes or barrels. They will need protection during the first winter, and should be set thickly in the ground, in a cold-frame or cellar, or, if there is no opportunity to protect them in this way, they can be heeled in in some sheltered situation and carefully covered with leaves and evergreen branches. In the spring the plants should be set in nursery rows and cultivated during the season. In the spring of the third year they will be large and strong enough to bear transplanting into the positions they are to occupy permanently; after that the plants will require no further care or attention. The Laurel grows in almost all soils except those strongly impregnated with lime, but in cultivation it flourishes most freely in a well-drained compost of sandy loam and peat. The Laurel may also be raised from seed, but the young seedlings grow slowly and require special care, so that persons unfamiliar with the business and without special facilities for raising seedlings, are not recommended to adopt this method of obtaining plants. The Mountain Laurel is grown largely in some European nurseries, and fine bushy plants, a foot high and as much across the branches, covered with flower-buds, can be imported and delivered in this city or in Boston in quantity at about thirty cents a plant.—Ed.]

Gorse and Scotch Heather in New England.

To the Editor of GARDEN AND FOREST :

Sir.—Can you tell me whether the Furze, or Gorse (*Ulex Europæus*), will stand the winter on the coast of Massachusetts, in a rather exposed situation?

And will any of the Scotch Heathers live in such a situation? Will you give me the botanical names of such varieties?

F. E. G.

[The Gorse was planted quite largely several years ago in Massachusetts, on the Island of Naushon, lying between the mouth of Buzzard's Bay and the Vineyard Sound, for the purpose of covering the ground and preventing the drifting of loose sand. It lived for a number of years, and plants may still be seen upon the island. It never spread much, however, and in severe winters always suffered. It cannot be considered hardy in New England, and its cultivation is not recommended, except as a garden-ornament in sheltered positions, or where it can be carefully covered and protected. The so-called Scotch Heather is *Calluna vulgaris*, a low, heath-like plant, with handsome purple flowers. It has been found growing spontaneously in one locality in Massachusetts, and it is not rare in Newfoundland and far northward on this continent. Its true home, however, is in northern Europe. Although a hardy plant, it cannot be recommended for planting in exposed situations on the New England sea-coast, as it often suffers in severe winters when not carefully protected. The plant which most

resembles the Gorse, at least in flower, which is really available for planting on the New England sea-coast, is the European Woad-wax (*Genista tinctoria*), a low shrub of the Pea family, with bright yellow flowers. This plant now occupies many hundred acres of sterile, hilly land near Salem, in Essex County, Massachusetts, near the sea-coast. It spreads rapidly, and when once it has taken possession of the soil, no other plant can dislodge it. The appearance which these hills present when the *Genista* is in bloom is striking and beautiful, recalling more clearly to the mind a Gorse-covered moor of Europe than anything which can be seen elsewhere in the United States. The *Genista*, however, has proved itself a dangerous and persistent weed in Essex County, and there is always danger that it will, when planted, spread over and ruin valuable land. It is only beautiful while in flower, being quite insignificant during the remainder of the year. There are such a number of dwarf native shrubs with beautiful flowers, or with handsome foliage, which can be used for covering rough and exposed situations along our coast, that it does not appear necessary to look to foreign countries for plants for this purpose. Plantations made of our native Roses, the Bayberry, the dwarf Sumachs, the different Blueberries, the Beach Plum, the Hudsonias, the dwarf Cherry, the dwarf Viburnums, the Sweet Fern, are suitable and appropriate for the New England coast. Such plantations, made without the aid of human hands, may be seen in many places along the shores of Cape Cod and Cape Ann. Nature, with all the wealth of material at her disposal in more favored climates, has never made combinations more harmonious in color, or more suitable to their surroundings. They put on in autumn, too, after the beauty of the spring and the summer have vanished, a richness of color which gives to our coast scenery, at this season of the year, a character peculiarly its own, and so beautiful that the mere suggestion of introducing into the scene any foreign element which cannot heighten and must diminish this distinctive charm seems undesirable, to say the least.—Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—I have been greatly annoyed by ants in the house, where they swarm through kitchen and pantries, and on the lawn, where they construct unsightly little mounds, and crawl over every one who dares to sit on the grass. What is the best defense against this invasion?

Lancaster, Pa.

E. M.

[First find the ant-hills which harbor them. This is not difficult if sharp watch is made of the directions in which they travel. Professor Cook, of Michigan Agricultural College, then attacks them by sinking a crow-bar into the centre of the mound till it reaches the level of the lowest gallery in the ants' nest. Half a gill of bisulphide of carbon is then turned into the hole, and a shovelful of clay is at once thrown on and trodden down compactly. This holds in the poison fumes of the volatile liquid, and soon destroys the last ant. In the latest Bulletin of the Massachusetts Agricultural College the same advice, practically, is given by Professor Fernald. A large ant-hill, nearly six feet square, next to the underpinning of a house, was doing much damage. The ground was undermined so completely that a person walking over it would sink in quite deeply, and the grass on the hill was nearly dead. Holes were made with a small stick, about fifteen inches apart and six inches deep, and two or three teaspoonfuls of the bisulphide were thrown into each hole, after which the holes were closed and the earth pressed down by stepping on them. The treatment was successful. The closing up of the orifice seems to be essential. Bisulphide of carbon is a chemical preparation that can be found at any drug-store. It has a most disagreeable smell. The bottle in which it is contained should be kept tightly stopped, as it quickly loses its strength when exposed to the air. The fumes should not be breathed while using it, because

they are injurious as well as disagreeable. As it burns at a temperature of 107° Fahrenheit, it should be kept away from fire.—Ed.]

Recent Publications.

Annual Report of the Division of Forestry, Department of Agriculture, for 1887: B. E. Fernow, Washington, 1888.

The Forestry Division of the Department of Agriculture was organized chiefly as a bureau of information, and the report before us, while giving an account of the methods by which this educational work has been carried on during the year, contains much besides that will afford instruction, provoke inquiry and stimulate interest. Like its predecessor, this report contains few statistics, for the good reason that the department has not at command the elaborate machinery needed to secure accurate figures. Some imperfect data in regard to the amount of forest planting in the West are given, and Mr. Fernow takes occasion to note that many reports of tree-planting in the prairie states are misleading exaggerations. Even when the number of trees planted is accurately given, they often include those set by the roadside and about dwellings for ornament and for shelter belts, as well as those in forest masses. But scattered trees can never make a forest, and it is unfair to divide the whole number of trees planted by the number required to the acre under the Timber Culture Act, and consider the result as the acreage of artificial forest. And even if the acreage planted under this act were correctly stated, we have no knowledge of the present condition of the trees, or what per cent. of them will be likely to live and thrive. Mr. Fernow rightly insists that we are using up our wood crop more rapidly than it reproduces itself. Those who doubt this swift reduction of our supplies because of our still abounding forest wealth and because it is true that in some parts of the country the wooded area is increasing on abandoned farm land, should remember that even where there is no absolute denudation the forest may deteriorate in quality, and that the new crop that is springing up on the old fields is quite inferior to the original growth.

This report deals mainly with a different class of subjects from those treated last year. The chief value of the last year's report was in the section which set forth the principles of forestry proper. The most interesting portion of the present report is that in which is outlined a system of study and original investigation with a view to place the practice of forestry in America on a rational basis. It is argued that if the Division of Forestry is to accomplish the most worthy results, it is time that it took a step in advance of its old work of compiling doubtful statistics, of recounting what has been done in the Old World, and of exhorting our people not to squander the forest wealth of the country. All of this was needed, perhaps; but what Mr. Fernow calls "missionary work" can safely be left to the public press and to the forestry associations of the different states. What is now needed is exact knowledge—such knowledge as can only be gained by careful experiment and study. It is to suggest the lines upon which such inquiry should proceed, and to make a proper co-ordination and subordination of the various fields of investigation that the topics have been grouped into systematic arrangement.

It may be that experience in studying and teaching will suggest some modification of this schedule, but as it stands it serves a good purpose in presenting to readers, who have not given serious and continued thought to the matter, an adequate conception of the wide range of subjects to which the American student of forestry can profitably direct his attention. And very plainly it would be to the general advantage if the Department of Forestry, the agricultural colleges, the experiment stations and private investigators should devote themselves, according to their several lights and abilities, to researches of the kind here indicated. It is true that forests have been and will be successfully planted and managed, and forest crops profitably harvested by men who know little, in a scientific way, of the life history of the trees they plant and fell, and still less of the general distribution of our forest flora or of the technological properties of different woods. It is equally true that there have been entire generations of fairly successful farmers who have had little or no exact knowledge of the sciences which underlie the practice of agriculture. But no one will contend that our agriculture has not been improved materially in recent years by the published results of scientific research. Farmers now talk intelligently of nutritive ratios and of the proper proportions of nitrogen, potash and phosphoric acid in their fertilizers, and it is this knowledge which makes our agriculture progressive and full of prom-

ise. It is not too early to begin the systematic study of forestry with the same purpose. It will be years, indeed, before the same care will be given to the production of forest crops here that is used in some countries of Europe. Our time for strictly scientific forestry has not yet arrived. But years will be required before we shall be able to collect the facts and experience we shall need, when the refinements of forestry, with its close calculations and intensive methods, can be practiced to advantage.

To this exposition of a plan of comprehensive study, Mr. Fernow adds some suggestive paragraphs on experimentation in the forest, the nursery and the laboratory, together with observations meteorological and climatic. The successful practice of the future must be based upon methodical experiments conducted persistently by men of scientific training. In no other way can data be furnished that will enable us to answer with confidence such elementary questions as: What is the best time to thin? At what period of growth can the forest crop be most profitably utilized? How do the financial results of natural reforestation and artificial planting compare? Mr. Fernow indicates the lines which these investigations are to follow, and illustrates, by examples, the kind of knowledge that is to be gained in this way. The entire section is most valuable as affording popular instruction upon points to which general attention has not been directed.

The report also contains a brief summary of the condition of the forests in the several states, notes on a few timber trees, certain bulletins which the division has issued during the year and much miscellaneous matter. Altogether, it admirably accomplishes its purpose to disseminate information, and it cannot fail to instruct the class of readers which it will reach and give them a clearer conception of the importance of the problems in forestry which now confront the country and of the proper means to employ if they are to be satisfactorily solved.

Recent Plant Portraits.

PTEROCARYA FRAXINIFOLIA, *Gardeners' Chronicle*, October 6th; a hardy tree belonging to the Walnut family, bearing in long, graceful racemes small hard nuts with broad, membranous wings. The finest specimen of this tree in the United States is believed to be in the Harvard Botanic Garden in Cambridge. There is a second species, a native of Japan, *P. stenoptera*, now sometimes cultivated, and of very considerable promise as an ornamental tree.

JUGLANS MANDSHURICA, *Gardeners' Chronicle*, October 6th; a hardy Walnut from Amurland, closely related to the North American Butternut (*J. cinerea*). This interesting species has been an inhabitant of the Arnold Arboretum for a number of years, ripening large crops of fruit there every year. It is a tree of compact and handsome habit, of considerable ornamental value, and the nuts are of a sufficiently good quality to make it quite possible that this species may in time become of value as a fruit tree in the Northern States, and in other regions where the English Walnut cannot be grown successfully.

PSEUDOPHENIX SARGENTI, *Gardeners' Chronicle*, October 13th.

LILIUM NEPALENSE, *Gardeners' Chronicle*, October 13th; a handsome Lily from the Central Himalayas, requiring greenhouse cultivation. The flowers are described as greenish on the outside, with the interior of the perianth an intense red-crimson color, with light greenish tips.

Notes.

The Chrysanthemum Show of the Massachusetts Horticultural Society will be held in Boston on 14th, 15th and 16th of November.

No less than 150 species of Primrose, divided into sixteen sections, are recognized by the German botanist, Pax, in his recent monograph of this genus.

The Forestry Congress in Atlanta will meet on December 5th, and not, as previously announced, on November 29th, which is Thanksgiving Day. The Southern Passenger Association, which embraces all the railroads south of the Potomac, and, on this occasion, the Pennsylvania system, so far as New York, has arranged for round-trip tickets to the great National Exposition in Augusta, Georgia, at one fare, and will grant stop-over tickets to attend the Forestry Congress in Atlanta. As the northern and southern societies will be consolidated in Atlanta, a large delegation is expected on December 5th. Full particulars can be had by addressing Mr. Sidney Root, Atlanta.

In the rich prairie soil of the Kansas Agricultural Experiment Station, where fertilizers and yard manure proved of little value, an application of salt at the rate of 300 pounds to the acre, increased the yield of wheat perceptibly.

Mr. T. S. Brandegee has discovered this summer *Pinus Torreyana* growing upon Santa Rosa, one of the small group of islands which lie off the Californian Coast in the latitude nearly of Santa Cruz. The discovery is an interesting one, as *Pinus Torreyana* has been considered one of the rarest and most local of American trees, being known formerly only in one very restricted locality in the neighborhood of San Diego, California.

Great baskets of the Fringed Gentian, the loveliest of all our late autumn wild flowers, appear this year in Boston in the hands of street flower-sellers. It would be difficult to conceive anything more beautiful than the dark blue of this delicate flower when thus seen in great masses. Very attractive, too, are bunches of the bright colored fruit of the Roxbury Waxwork (*Celastrus scandens*), surrounded with *Kalmia* leaves, which appear just now very popular with people who purchase flowers in the streets of Boston. Every few minutes a woman may be seen with one of these bunches on her dress or in her hand.

The tropical plants which have filled the two large vases in front of the City Hall, in Boston, have been replaced with *Chrysanthemums* in full bloom. The effect is excellent. The decorative value of the *Chrysanthemum* is only just beginning to be appreciated in this country, and they will grow in popularity as they become better understood. They can certainly be used with great advantage in this way, and if early flowering varieties, to be followed by those which bloom later, are selected for the purpose, there is no reason why vases and many garden beds, especially in cities, cannot be made attractive for at least six weeks after the frost has destroyed the beauty of more tender plants.

The gelatine which is contained in the "edible birds'-nests" of the Orient, and which, of course, is what constitutes their nutritive quality, was once supposed to be a secretion from the salivary glands of the bird itself—a species of swift. But it has been proved to be a Sea-weed, which the bird often brings from long distances. Mr. J. B. Steere, writing recently in the *American Naturalist*, describes a visit which he paid under the guidance of professional nest-hunters to the caves where these birds build in the Philippine Islands. They build in utter darkness, and it takes about a month to complete a nest. This the hunter must secure before the eggs are laid, otherwise it would naturally be unavailable for culinary purposes.

A correspondent of the *Revue Horticole*, writing from Nancy, speaks enthusiastically of the new race of hybrid Gladioli obtained in the famous horticultural establishment of Monsieur Lemoine, by crossing *G. Saundersi* with the so-called Lemoine Hybrids, obtained by mingling the blood of *G. aureo-purpuratus* with some of the varieties of *G. Gandavensis*. The shape, size and the markings of the flowers of this new race are said to be marvelous and to display a beauty heretofore unknown among Gladioli. It is probable that one or two of these varieties will appear in the new edition of the Lemoine catalogue and will be offered for sale. Some of the seedling Montbretias, raised in the same establishment, are said to show great improvement in the form and in the color of the flowers.

The general introduction into commerce of lumber manufactured from the Gum-tree or Tupelo (*Nyssa sylvatica*) is hindered by the practice of some dealers of attaching false names to it, with the idea of disguising its real character. In England it is sometimes called Satin Walnut in the trade; in this city it can be found under the name of Hazel-wood; and it has appeared as Arkansas Redwood. Gum is a valuable wood when its peculiarities of excessive shrinking and warping are guarded against by proper methods of manufacturing and seasoning, but it gains nothing by having false and misleading names attached to it. And in the same way Sycamore lumber is just as valuable when it is called Sycamore as when it is called Satin-wood, as is sometimes the case in eastern markets.

Colonel Pearson states, in the *Philadelphia Weekly Press*, that the cost of treating an acre of Grape vines with the copper sulphate solution, which has proved efficacious against both the black rot and the mildew, need not exceed, for labor and material, ten dollars. The solution which he uses is known as the Bordeaux mixture of copper sulphate and lime, the

formula for which was given in the issue of GARDEN AND FOREST for September 19th. This mixture is a whitish liquid resembling somewhat thin milk of lime, and the precipitate should be constantly stirred as the vines are sprayed through a Cyclone nozzle. The first application should be made before the vine-buds open in the spring, and in seasons favorable to the growth of the rot fungus, it should be repeated every three weeks. For a certain protection against the rot, every cluster and every berry must be reached by the spray, and this can be easily accomplished with the machinery now at command.

Early grafting of the Cherry in the open air is always recommended, and dormant buds are considered necessary in grafting under cover. The advice is well founded, but the true reason for it is rarely given. If the stock is as forward in growth as the scion, a union of the two can be made quite late in the season. The essential requisite is that the wood of both should be in the same condition. In a late bulletin of the Iowa College Experiment Station, Professor Budd cites an instance where it became necessary late in April to take up several valuable Cherry-trees loaded with fruit buds. All the scions were cut off down to the two-year-old wood, and set on Mazzard seedling roots in the graft-room. The grafts were put in the nursery a few days later, and over ninety per cent of them made strong growth. In this case the buds were started, on one variety, so as to exhibit the points of the embryo leaves, yet the roots taken from the cellar had started fully as much. If the seedling had been kept dormant in the ice-house, probably not a single scion would have united with them. This principle applies to all top-working in the open air of Apple, Pear, Cherry, Plum, etc. If the work is deferred until the buds on the stocks are well started, the scions should be about equally advanced.

In 1883 Professor Budd imported one-year-old Cherry trees of such varieties as he considered promising for the north-west, from the valley of the Moselle, in eastern France, and eastward to the Volga, in Russia. The trees have, so far, proved as hardy as our native Plums, and many of them fruited heavily this year. The fruit is satisfactory in quality and color, but not in size. The smallness of the fruit may have been due to the strong growth of new wood, induced by severe cutting for scions in autumn. In a late bulletin Professor Budd recommends that these trees be headed low, and adds that, even in western Europe, low cordon and bush training of the Cherry is becoming common. In eastern Europe, in sections remote from large bodies of water, all stone fruit trees are headed low. In the Volga region the Cherry is grown in bush form, with several stems like the Currant or Gooseberry. Experience has also favored very low stems, or even bush form, in all the prairie states. Often the stems are fatally injured when the twigs show no discoloration. Fortunately, many of the east Europe varieties favor the shading of stems by their pendent habit of growth. But even with these it is best to have low stems, the lower the better.

A hundred years have passed since the Botanic Garden at Calcutta was established, and Dr. George King, the superintendent, joins to his last annual report an interesting historical sketch of this famous institution. It was founded by the East India Company, upon the recommendation of one of its servants, Colonel Robert Kyd, who became the first superintendent, holding the position until his death in 1793. Among his successors appear the names of many distinguished botanists, of whom the best known are Roxburgh, the author of the earliest Flora of India; Wallich, whose three volumes upon some rare Indian plants are among the most sumptuous in botanical literature, and Dr. Thomas Thompson, the co-worker with Sir Joseph Hooker in Indian botany. The garden has been of immense service in making known and distributing Indian plants and in the introduction of useful plants, like the Tea and the Cinchona, into Indian cultivation. The garden was devastated by a terrible cyclone in 1864, and a second cyclone, a few years later, almost ruined the few plants which had escaped the first. A troublesome weed, *Imperata cylindrica*, then spread rapidly over the ground of the whole garden, which had become exposed to the sunlight by the destruction of the trees, and when Dr. King was appointed superintendent in 1871, it was in a miserable condition. He has, however, entirely replanted the garden with reference to landscape effect and erected new conservatories and a new building for the immense herbarium, principally of Asiatic plants, which is connected with the garden, and which is constantly enriched with new collections. It is said that of the trees which were growing in the garden in 1867, the great Banyan tree is the only one now left standing.

Chrysanthemums.

THE remarkable popularity of the Chrysanthemum in recent years can hardly be classed among those transient floral epidemics, so many of which are on record in the history of horticulture. The rage for Sunflowers and Daisies, with many another ephemeral caprice of this sort, died out as suddenly as they arose, not because the flower which chanced to be the prevailing fashion had no merit, but because an exaggerated or fictitious beauty and value were claimed for it. The interest in the Chrysanthemum has had a slow and steady development, and it is based on the genuine worth of the flower. It appears at a time when rivals are few and its blooming period extends over a long season. It ranges through a series of rich, mellow tones of color, and no flower lends itself more readily to the production of decorative effects. In form it has the merit of symmetry, without a hint of rigid formality or any chilling suggestion of artificiality, such as characterizes a double Dahlia or a prize Camellia. No other flower equals it in the diversity of form which it assumes within the limits of perfect proportion. Each variety and class of varieties shows such a marked individuality in the shaping and arrangement of its parts, or such a delightful waywardness in the curving and twisting of its florets, that one can examine a hundred flowers and never find the outline of a single one repeated. When it is remembered, too, how much of promise for the future of the Chrysanthemum there is in this free habit of blossoming out into novel and graceful forms, we can rest satisfied that not even the Rose will more securely maintain its position as an established favorite among flowers.

The history of the Chrysanthemum's development from its earlier and more simple garden forms, is most interesting. It will suffice for our present purpose to note that Loudon, in his Cyclopaedia published in 1824, speaks of numerous varieties "recently obtained from China," where the flower had long been cultivated. He enumerates forty-four varieties, of which few are now to be found in cultivation. The Large Lilac is one of those which still may be found in old gardens on Long Island

and in other parts of this state. Perhaps several of them still survive in old places still further south. Some of them, like the Tasseled Yellow and White, the Yellow Waratah and the Golden Lotus-flowered, would be appreciated now if they could be re-introduced and cultivated under approved modern methods. Samuel Broome, in 1857, published a list of the varieties then growing in the Temple Garden, London, and among them were 184 varieties of what was known as the Chinese Chrysanthemum, eighteen Large-flowered Anemones, 140 Pompons or Lili-puts, and thirty Anemone Pompons. Of these, there are found in collections to-day, twenty-five Chinese, eight Chinese Anemones, twenty-one Pompons and ten Anemone Pompons. It is hardly twenty-five years since flowers belonging to the Japanese section were introduced to general notice. It was in 1865 that the *Gardeners' Chronicle* reported that Mr. Veitch had sent home "three very distinct forms, evidently the representatives of many beautiful productions yet unborn." Two of them had peculiar ligulate ray-flowers, all or nearly all of which were drawn out into extremely narrow, sharp terminations, now and then inclined to fork. The third was of quite another kind, close-headed, incurved, with all the florets divided into two irregular and unequal lips. The now famous Grandiflorum was sent by Robert Fortune to John Standish, of Ascot, and shown by him as early as 1862. At the same time were exhibited Laciniatum and Japonicum, the former spoken of as a "distinct Japanese variety of the Chinese Chrysanthemum with white flower-heads composed of fringed tubular petals." The report speaks of the latter as being remarkable for its slender, tubular, curved florets. How all these peculiarities have been intensified since their introduction, and fused together into new combinations, is made plain in any ordinary collection to-day.

Enthusiastic cultivators in this country recognized the value of the Chrysanthemum long ago, but it is scarcely more than seven years since this flower first attained its real popularity here. Mr. H. P. Walcott, in Boston, Mr. W. K. Harris, in Philadelphia, and Mr. John Thorpe, in New York, were most conspicuous in bringing it into public favor. The importation from Japan, by Waterer, of some fifty varieties, in 1883, many of which were most distinct and beautiful, gave a new impulse to hybridizing, and now the new kinds that appear every year are almost numberless. At least 10,000 tried seedlings have been on exhibition for the first time this year. The diversity of form and color displayed is almost infinite, and the various strains have been so intercrossed that the seeds from a single flower-head will often produce examples of the types most widely separated in structure and size, together with intermediate and kindred forms. The strong propensity of the Chrysanthemum to variation has been of great advantage to the originators of new varieties, and, by careful selection, the improvement in color has been as striking as the changes in form. Shades and tints which were unknown in this flower a decade ago are now common. Maroons, crimsons, rose, pink and buff have all become more decided. The markings of parti-colored flowers upon the tips and along the marginal lines have become more distinct, and the production of a scarlet flower is not despaired of by those who have done the most to bring out the newer and formerly unknown shades. It is small wonder, then, that exhibitions devoted exclusively to Chrysanthemums have been held in at least a dozen of our cities this year, while only four years ago Boston, New York and Philadelphia alone had such displays.

No one can prophesy in what direction the next marked improvement in the Chrysanthemum may be looked for; but, judging from the past, striking variations from the forms we are now familiar with may be expected. Those who studiously note the development of new seedlings are quick to mark the appearance of slight peculiarities, for these may be the forerunners of distinct types. For some

years the appearance of hair-like growths from the under side of an occasional floret has been observed, but they were never sufficiently numerous to give any character to the flower. But last year the remarkable variety, Mrs. Alpheus Hardy, which was figured in the first number of this journal, was found in a Japanese importation, and in this each floret was thickly set with these slender growths, giving an entirely new character and expression to the head. Up to a comparatively recent time the section with lacinated florets invariably had small heads, which did not show distinctly this characteristic. Some of the newer varieties of this type have florets three inches long, with four or more bifurcations, and spreading at least to three-quarters of an inch in width. In many cases the florets, for two-thirds of their length from the disc, are tubular, and then branch abruptly into their particular toothed forms. And the disposition of the florets is quite as interesting as their shape. In many cases their arrangement is flat; again they are reflexed; while in others still they are incurved and confused into a globular mass of slender shreds, which often show the upper and lower surface in each floret. But slight modifications of these characters are needed for the origination of a new class of *Chrysanthemums* as distinct as any heretofore produced.

But whatever the forms with which the *Chrysanthemum* may be endowed in the future, we may feel sure, from what we know of its inherited tendencies, that the flower will continue to show that freedom and fluent grace of outline which so strongly commend it to the taste of the time.

Piazas.—II.

WE explained last week that there is no need for piazzas so extensive as those which a few years ago were commonly attached to our country houses. Their full purpose may be served in almost every possible case if they are placed only on one side of the house, or on a corner, so as partly to encircle two sides. The interior is thus left more free for the admission of light and sun, and architectural effect is improved, while convenience is amply considered. Especially is this true if the covered piazza is supplemented by other external features.

Indeed, the chance to secure such features is in itself sufficient reason why piazzas should not be too large. In a house of the old piazza-encircled type it was difficult, for instance, to emphasize the chief entrance, which, if a home is to have the right effect, should always be hospitably prominent. Upper balconies, which are often so useful as well as pretty, could not be well placed above the long piazza roofs. Terraces were hard to treat, and that delightful feature, the Italian loggia, was impossible, at least on the ground floor.

Of late we have begun to employ these other external features with the happiest results in the way of comfort as well as beauty. The front door is accentuated by an independent porch, often usefully extended over the driveway. Upper balconies are attached to the chief bedrooms or thrown out from any window which chances to command a particularly attractive view. Uncovered terraces of turf or of stone are formed where needful, and a portion of the piazza itself is often left uncovered, supplying a pleasant place of resort when dull weather or autumn cold renders a roof unnecessary, and delightful at night in warmer weather. And loggias are seen in both the lower and the upper stories.

No architectural innovation is more to be commended than the use of the loggia, which may be described as a recessed piazza—a piazza set back into the body of the house, flanked at either end by the walls and covered by the projection of the upper story. In Italy it does not usually appear on the ground floor, for there this floor is not devoted to the chief apartments; but its effect is just as good when it is adapted to our own customs of building and living. In certain very exposed situations the piazza may well be entirely banished in favor of a

loggia, and in others a small open piazza may be effectively supplemented by a larger loggia; while in almost every country house at least a little loggia should be introduced either up-stairs or down. Our climate is so very variable that too careful a provision can hardly be made for changing winds and skies and temperatures.

Another useful device is a terrace protected by a trellis over which are trained vines that will soon form a thick summer covering, while their naked stems will in winter admit light and sun to the rooms behind. Or an awning may be used if its effect is preferred, or if there is danger that the vines will harbor too many mosquitoes. It has, indeed, a certain advantage over vines in that it may be rolled back in dark weather and supported on movable posts, which can be taken down in winter. Of course neither of these expedients really fills the place of a true piazza, for although they screen from the sun they admit the rain; and if they are of great extent they detract from solidity of effect in the house. But a small vine-covered terrace is never inadmissible, and a small awning is rarely offensive; and they may at least be recommended as supplements to a true piazza, or even as substitutes for it in houses occupied throughout the year and in positions where a permanent piazza-roof would be a serious inconvenience.

We have already said that the pleasing treatment of piazzas is one of the most difficult of current architectural problems. It is true that charming houses with long verandas have been built for generations in certain southern countries. But although we may get valuable hints from them, they cannot be used as models. Ours is not a truly southern climate, but one in which almost tropical heat alternates with almost Siberian cold. Our more complicated habits of life demand more complicated ground-plans than those which serve, for instance, for an Indian bungalow, and every deviation from a simply outlined and low-roofed form makes the right architectural use of piazzas more difficult. Yet until within quite recent years the problem was hardly recognized as such. No attempt was made so to unite the piazza with the house, in both form and material, that it should seem an integral part of it, and not a mere attached shed. Whatever the material of the house, the piazza was built of wood, and it was simply tacked on to the walls without the slightest thought of union. Its roofs had no relation to the roofs of the house, and its forms were very slight and fragile—the jig-saw running riot in a vain effort to adorn it, but no serious attempt being made to build it beautifully. To-day we see a very great change for the better. The piazza is treated—with more or less success, of course—as part and parcel of the house. It is borne by a solid substructure instead of by isolated posts which allow the cellar walls to be seen, or by a chicken-coop lattice. This substructure is often continued around the piazza as a solid parapet, some three feet in height, which has both artistic and practical merit, for it increases solidity, and therefore dignity of effect, and it screens the feet of the occupants from the wind and protects them somewhat from the gaze of passers while interfering not at all with coolness or with freedom of outlook. If the house is of brick or stone the same material is used to build posts of the piazza, or if wood is employed, simpler and more artistic forms are chosen for them. And it is covered by an outward sweep of the main roof of the house, or by such a disposition of an independent roof that it may play a conspicuous and harmonious part in the general outline of the building. On houses of the revived colonial type the piazza naturally has a flat, balustraded roof, which may be utilized as an uncovered balcony for the upper floor, or some parts of it may be roofed in again as an upper piazza. Difficulties are hardly as great, perhaps, when a flat roof can be employed, as when a steep one is required by the fashion of the greater roof above. Yet, whatever the scheme, we here and there find instances, in ever-increasing number, where it has been thoroughly well managed. Of course an ideal degree of success is seldom seen as yet, and many of our new houses

are quite as ugly in their own way as the shed-encircled boxes which preceded them. And they are, perhaps, even more distressing to the eye; for the old house had at least the merit of frank simplicity, while the new one has often the great demerit of seeming a labored effort after as much eccentricity as possible. Yet, taking good and bad together, the general improvement which has marked our architecture in recent years can nowhere be more clearly read than in our country homes. And it is a most significant proof of the genuine, vital and promising character of our progress that these homes should have been so greatly improved, not through the direct imitation of foreign models, but through the development of indigenous fashions, and the incorporation—despite difficulties which might easily have been thought insuperable—of the “vernacular” piazza.

A Glimpse of Nantucket.

FOR many years the population of Nantucket has been steadily declining. Counting nearly 10,000 souls in 1840, it does not count 4,000 now. And these may be held to represent a “selection of the unfittest,” for year by year the more energetic and intelligent youths of the community have gone to seek their fortunes in the outer world. Meanwhile, until quite lately, the island has been scarcely thought of in the outer world save in connection with bygone whales, and has generally been described as a featureless expanse, interesting simply as a bit of sandy wilderness isolated in a wilderness of waves.

Now, however, a change has come—not, indeed, over the numbers or the spirit of the natives, but over the minds of those whom they call “off-islanders.” Summer tourists have discovered the cool, bracing equanimity of the Nantucket climate, the homely picturesqueness of its quiet town, and its rich facilities for bathing, boating and fishing; and they flock to its shores in increasing thousands summer after summer. How the islanders lived before this influx began, some twelve years ago, it is hard to imagine, for I have never seen a place more destitute of signs of an attempt to earn a living. There is now no whaling, which is largely the fault of external circumstances; but there is scarcely any sheep-raising, and this must be the fault of the islanders themselves. Great flocks once pastured over the island. Wool was then the main concern and was chiefly used at home. But now, with improved means of transport and the summer immigration, it seems as though a little energy might make the raising of mutton profitable. Agriculture is almost as non-existent as sheep-raising. Nearly the whole population lives in the town and a few distant villages. Farm-houses are few and widely scattered, and the cultivated fields which surround them are rough and very scanty. In the town and along the edges of the shore the summer colonists are likewise gathered, so that a mile away from this shore one can fancy one's self a hundred miles away from anything that approaches to human activity, wealth or progress.

More negatives must still be used before I can begin to tell what does exist in the central regions of Nantucket. In the first place, there are no stones. Knowing that the island was formed during and after the glacial epoch, and is a mere mass of “drift,” one does not look for the bed-rock of the mainland to which, for a time, it was attached. But it seems more reasonable to expect those boulders which are strewn over the whole surface of New England, and nowhere more thickly than along the coasts nearest to Nantucket. Yet they do not exist. Broadly speaking, the island is divided into a higher eastern and a lower western portion of almost equal areas. The latter I had no time to visit during a brief two days' sojourn; but many hours of diligent driving showed me the whole of the eastern portion, and I could count on my fingers the stones I saw. Of course, this means that there were none of the picturesque walls which I had left behind in Plymouth County, and which are to be found again on Block Island a little to the westward. But, from a practical point of view at least, the lack of such walls does not greatly matter. Where there is so little to fence in, only the lover of beauty need regret the lack of good fencing material.

Finally, there are no trees on Nantucket, except those which have been planted in the streets of the town, and some scattering plantations of Pitch Pine which were made about forty years ago midway between the northern and the southern shores. The farm-houses stand naked and alone, and even along the many little lakes and ponds one sees neither groves of trees nor

thickets of shrubs. The so-called Pine woods, moreover, are almost caricatures of the term. There is no more dauntless and long-suffering tree than the Pitch Pine, but it can seldom have struggled with greater difficulties than on Nantucket. No individual rises more than ten or twelve feet above the soil; all are grotesquely distorted by the fierce sea winds; many are scarred and embrowned by the touch of fire, which starts readily and runs persistently in the dry matted grass; and they look, in consequence, like a collection of ancient dwarfs, not like young woods with possibilities of further growth. Yet from even a little distance these woods actually seem to deserve their name, for everything vertical “tells” with extraordinary force in this landscape, where vertical things are very few, and where slight inequalities of surface, therefore, give the look of far horizons to spots quite near at hand. The eye is so entirely deprived of help in its calculations, that even experience does not soon teach it how to compute distances or dimensions. The first mistake I made was to exclaim at the presence of a great hotel in the middle of a moorland wilderness, the building being, in fact, but a farmhouse of moderate size. And after several such mistakes, with a full sense of the likelihood of error, I pronounced a pair of isolated objects to be tall chimneys about five miles off and found them merely tombstones not a mile away.

These groves of gaunt yet dwarfish Pines, then, are the only trees which meet us outside the town, although we are told that White Oaks once grew in certain places large enough to be used for building purposes. The earliest local records speak of “meadows, woods and uplands,” and one district bore the name of the “Long Woods;” but a full century ago the island was represented as “wholly destitute of firewood,” and dependent, as it is to-day, on Cape Cod for its supply. In the town a great deal of planting was done in former years. When we stand on one of the railed “roof walks” that are so characteristic of a community which perpetually went down to the sea in ships, the panorama of gray roofs is interspersed with an almost equal quantity of foliage. The Elms have stood their long battle with the sea wind fairly well, but more interesting are the Ailanthus trees, which quite as frequently appear. One-sided, as a rule, and often naked of foliage save towards the extremity of their branches, their gray bark and picturesque structure harmonize admirably with the gray picturesqueness of the old unpainted houses; and their foreign air seems appropriate in a place which once was filled with trophies of every kind from many a distant shore.

But the real interest of Nantucket lies in those wide tracts away from the high sandy cliffs where, as far as the eye can reach, no tree is in sight. The prospect is peculiar even to eyes familiar with Block Island and the eastern portions of Long Island. At Block Island the surface undulates perpetually and abruptly, is thickly bestrewn with boulders and shows scarcely any vegetable covering save a close, yellowish grass. At Montauk there are also wide, boldly rolling stretches of such grass; but others where white sand is spotted with great tufts of *Hudsonia*, and others again where moisture has produced beautiful thickets of shrubs and veritable little forests filled with many species of trees. But at Nantucket the surface is either quite flat for miles or gently rolling in long swells; the ponds are encircled merely by a border of sedges and tall grass, and seem to have no effect upon the soil beyond; there are no reaches of naked sand, and few where the grass is not thickly beset with flowering plants. Where it grew most abundantly it was filled in September with Asters and Golden Asters and Golden Rods and Everlastings—all stunted by the wind to a few inches in height, but vigorously blooming—and with purple *Gerardias*, showing larger and more deeply colored flowers than I had ever seen elsewhere. But the most characteristic and charming tracts were those which bore no grass, but were covered by a close growth of low undershrubs and trailers—*Hudsonia* of both species, Bearberry and the Broom Crowberry. Acres upon acres in one direction were covered with the last two alone, alternating in large patches and growing with splendid luxuriance, the Bearberry clothing even the sides of the road with a thick mat of glossy leaves and dark red fruit, and the Heath-like Crowberry rising in dense miniature evergreen thickets, and contrasting exquisitely with its neighbor. A prettier combination I have never seen, and it is hereby recommended to the owners of sandy sea-shore places as an excellent substitute for a turfed lawn. It is as delightful to walk upon as to look at, owing to the springy, Heath-like quality of the Crowberry stems. *Hudsonia* did not grow with as much luxuriance as at Montauk, yet it was often beautifully effective here and there. I was told that the true Heather (*Calluna vulgaris*) could be found in a few spots on the island,

did one know where to look, and its name is included in the list of native plants printed in the local guide-book.

This list—compiled by Mrs. Owen, of Springfield, Massachusetts—reveals how rich the island flora is. From the botanist's point of view the abandonment of sheep-raising must be accounted fortunate. For, as another contributor to the guide-book writes, when sheep were allowed to roam at large over the commons, it was only by the most diligent seeking that the botanist obtained perfect specimens of any flowering plant. "One feeble specimen of the blossom of the *Hudsonia tomentosa* could be found in perfection where now, freed from the sheep, . . . its yellow flowers are to be had for the glancing. Even the varieties of the Golden Rod, . . . which furnish the rich covering to our commons at times, were not a familiar feature, though known and specified by the scientists of the island." Then it must have been true that Nantucket was a barren waste to the eye; but it is truer to say at this present time that it is a garden of flowers from summer's end to end.

And, according to the belief of many persons whom I met, it might be made a wealth-producing garden, too. The soil, it is said, would be well adapted to certain cereal crops, were it only manured a little; and, even now, the vegetables it produces are of excellent quality. It seems as though there must soon come a time when these vast tracts of now unprofitable land will be turned to some account, perhaps by a revival of energy on the part of the islanders, perhaps through the advent of "off-islanders" intelligent enough to seize the advantages of a spot where a house, with considerable land about it, may be bought for one or two hundred dollars, and where the rapid growth of a summer population must create an enormous demand for market-garden products. But the time to see Nantucket is before this day arrives. Already the aspect of the town and of many parts of the shore has been grievously altered by the tourist throng; and when the savage simplicity of the interior shall have been softened beneath the plow, Nantucket will look a good deal like the rest of the world. To-day, when one turns his back upon the shore, it seems unique; and to an eye which can appreciate a landscape where almost all the conventional attributes of "natural beauty" are wanting, it seems uniquely attractive—or perhaps a better word would be, impressive. A splendid sky and the breath of a tearing wind tell us of the splendid sea, even when it lies out of sight. Seldom in civilized regions are we swayed by such a sense of breadth, vastness, freedom and the spontaneous action of elemental forces. Seldom do we see such beauty of color created with factors of such simplicity. And everywhere under our feet is the wide carpet of flowers and herbage in endless variety, in perpetual harmony and loveliness. The mainland is more picturesque; Montauk is grander; Block Island is more singular in surface conformation. But nowhere else on our coast is there so broad an expanse of uncultivated land, so simple as regards large features, so varied as regards those of minor size, so impressive in a general view, so interesting to the eye of minute examination.

M. G. van Rensselaer.

New York.

"The practice of leveling the surface has done much mischief both in park and pleasure ground. . . . When from any circumstance spare earth is to be disposed of in the pleasure ground, it is usually applied to the filling up of any hollows that may fortunately exist; whereas it should generally be used to increase any indications of undulating forms, as even the smallest variety of this kind is highly advantageous. It will be safer for the unpracticed eye to increase the existing varieties of the ground rather than to create new ones, the arrangement of earth for this latter purpose being an operation of considerable difficulty; whereas a moderate degree of caution cannot well fail in the former."—[W. S. Gilpin's "Practical Hints on Landscape Gardening," London, 1832.]

"Wherever Nature has herself glorified a country and made a picture bounded only by the horizon, as in many parts of Switzerland, Italy, Southern Germany, and even our own Silesia, I am strongly of the opinion that park-works are superfluous. It seems to me like painting a petty landscape in one corner of a beautiful Claude Lorraine. In such places we should content ourselves with laying out good roads to make the fine points more accessible, and here and there the cutting of a few trees to open vistas which nature has left closed. Around the house, however, we want a pleasant garden in a limited space and in contrast with the surrounding country. In such a garden we no longer seek the variety of nature, but rather convenience, agreeableness and beauty."—[Puckler-Muskau, 1834.]

Foreign Correspondence.

London Letter.

WE are now fairly advanced into mellow autumn, and the atmosphere of the horticultural world here is more than usually fruity. Little is talked about in matters horticultural except fruits. One hears of fruit-growing companies to be started and of fruit-growers' associations, while fruit conferences and fruit exhibitions are common in London and the provinces. We seem to have suddenly become aware that England is pre-eminently a fruit-growing land; that we have wasted millions in buying fruit from the foreigner; that thousands of men have lost, or rather neglected, opportunities in making bulky fortunes by fruit culture for market. Some enthusiasts go so far as to say that fruit-growing for profit is the only panacea for the depressed state of the farming interests in this country. Mr. Gladstone and other great men have pronounced in favor of extended fruit-farming, but even this does not appear to excite the stolid nature of the British farmer, who smiles mildly at the new "fads," and keeps on growing corn and meat as his fathers did before him. "Why allow Americans to send us the best Apples that the markets can supply, when we can grow fruit as fine as theirs?" This is one of the stock phrases of the promoters of fruit-growing companies, so that if anything really solid results from all the present excitement about fruit-farming, it will be a straight hit at Americans, who have taught us how to grow, how to select and how to pack Apples in order to reach our markets in as fine a condition almost as if just gathered from the trees. But Americans have nothing to fear from this passing fruit talk, at least for many years to come. It does very well to fill in a quiet interval, for nothing serious, I fear, will result from it, and when, next month, gardeners and others are engrossed in their Chrysanthemums, we shall hear little of fruit-farming except from the few who have real interests in the movement. The companies just started for fruit-farming are evidently believed in, for the Rothschilds and other great people have taken shares in them freely.

There previously had been some minor fruit exhibitions and conferences held at the Crystal Palace and other places, but the chief event in this way is now taking place in the garden of the Royal Horticultural Society at Chiswick. During all this week there has been a great gathering of those interested in fruit, fruit-nurserymen and private gardeners chiefly, very few actual fruit-growers for market. There is a very large exhibition of Apples and Pears, numbering over 5,000 dishes, the bulk of them very fine fruits, from all parts of England and Scotland. But you see there only a repetition of the large exhibition of Apples in 1883. The same collections of fifty sorts and so on; very fine examples, no doubt, of very fine varieties, but that is all. There is a great ado made about correct nomenclature, as it is loftily called, and little wrangles among gardeners about the proper names of such and such a variety are not infrequent. I will not attempt to detail the exhibition, as I know it would be of little interest to your readers. It is nothing but an exhibition, a fine show of the leading sorts of Apples grown by English gardeners for the gentleman's kitchen and table. I did not see one collection of sorts grown exclusively for market. There was not one exhibitor who sent a half a dozen sorts, and said: "These sorts are, in my opinion, the best to grow for the market. I live in Sussex; my soil is a deep loam resting on gravel; the situation is exposed and high, not subject to late frost." This is the kind of information that would be really useful, for you would get the opinion of a practical man from a given locality, and we should see the sorts he has selected as suited to his particular market. The same could be done in the case of selections for private gardens, which must necessarily be larger. It is acknowledged that we have far too many sorts of Apples; the lists of every large fruit-nurseryman are quite bewildering to the amateur who wishes to select a few of the best. What we

want to know is the process by which Americans found out that the Baldwin, the Newtown Pippin and other standard American Apples were the best for the market, and then see if we cannot find a selection to equal yours. I frequently have to make selections of fruits for new gardens, and I have sometimes been asked to plant nothing but American sorts of Apples, for "You know," say my clients, "there is no English Apple to come up to a Newtown Pippin or Baldwin," and it is hard to tell them that Apples cannot be grown in this country in such perfection as they can in the United States.

The papers read at the Chiswick Conference took a

New or Little Known Plants.

Rosa Nutkana.*

THE most showy of our western Roses, as well as the most clearly defined, with the exception of the delicate *Rosa gymnocarpa*, is the Nutka Rose. It has the largest flowers and the largest fruit of any of our species, and its armature is liable to become on occasion the most formidable.

It is frequent along the Pacific coast from the Alaskan peninsula to the Columbia River, where it was first collected by Menzies upon Vancouver's visit to that region,

Fig. 70.—*Rosa Nutkana*.

more practical turn than the exhibition, and some sound information was conveyed in them, as also in the discussions that followed the reading of each. All these papers will be collated in book-form and published by the Society, and which reminds me of the thorough way in which the reports of your leading horticultural societies are carried out. Let us hope that this present effort to establish fruit-farming in these islands will take root, and tend to make us more of a fruit-eating nation than we are at present. I was told the other day, by an American who has resided in England, that an American eats ten times as much fruit as an Englishman.

W. Goldring.

London, October 20th, 1888.

and somewhat later by Haenke at Nutka Sound. It ranges eastward from the coast through the mountains near the boundary to north-western Montana, and thence southward into Utah. It is rather stout in its habit, and with rather broad foliage, very rarely nearly spineless, usually armed with broad, flat spines at the base of the leaves, and occasionally, especially the young shoots, with scattered prickles. The spines are either straight or recurved, and sometimes they become larger even than they are represented in our figure, and very numerous. As usual in our Roses, the pubescence is very variable, the leaves being either per-

fectly glabrous and bright green, or softly pubescent, and very frequently resinous-puberulent, in which case, as in other species, the teeth are usually also glandular-serrulate. The inflorescence is ordinarily wholly smooth, hispidness occurring but rarely on either the pedicels or any part of the flower. As in all the other species of that region, in distinction from most of those of the Rocky Mountains and the East, the sepals never have lateral appendages or lobes. The fruit is globose or somewhat depressed, of a bright scarlet, and often over half an inch in diameter.

Our figure has been drawn by Mr. Faxon from a plant grown at the Arnold Arboretum. S. W.

Vegetables in Frames.

AMONG the vegetables now in frames are Lettuces, Radishes, Parsley, Endive, Chives, Spinach, Dandelions and Sorrel. All frames containing these should occupy warm, sheltered places, with a full sunny exposure, and be so situated that snow or rain-water will readily run away from, rather than lodge about, them. The more sunny and sheltered the exposure, the better will the vegetables thrive and the less covering will they need to exclude frost. See that the frames are in good repair; that all parts fit properly and snugly; that no openings are left at the ends of the rafters or elsewhere in the frames for the searching winds of winter to find. And see that the sashes are well glazed. If they are not perfectly water-tight, take a sash-brush and some thick white paint and run along the sash-bars, so as to close up any apertures by the edges of the glass through which water may drip. Have the frames well banked around with earth or coal-ashes, or if you use manure or leaves, lay a board on top of these to keep them dry.

While it is well to have the ground in which these frame crops are growing moderately moist, it should not be kept soaking wet, as must be the case where frames have been left open to the recent incessant rains. Therefore put on the sashes in the event of wet or snowy weather, keeping them tilted up to afford abundant ventilation. When frosty weather comes the sashes may be shut down, for, while it is unwise to keep vegetables in frames close and warm, freezing them does them no good, and hard frost hurts them. Store-vegetables—like young Lettuces that are being kept for transplanting later into hot-beds—should not be protected from light frosts, for the hardier they are, the better they will keep till required for transplanting.

The best covering we can have for frames is straw mats and light wooden shutters. These mats are made of long, flail-threshed rye-straw and marline, and of a length and breadth to suit. We make ours four feet wide, seven feet long and three-quarters of an inch thick, running five times lengthwise with marline. So long as these mats are kept perfectly dry they are a capital protection against frost, but if wet, frost soon finds its way through them. Under light wooden shutters they can be kept quite dry, and two mats thick and a shutter over them is good enough protection in a sunny place against twenty-five degrees of frost. There is a current idea that a heavy shutter is a better protection against frost than a light one, but this is contrary to my experience. I like light wooden shutters, of half or five-eighths inch pine stock, tongued and grooved, and put together in white lead; or, if the stock is thoroughly dry and well seasoned when the shutters are being made, and the boards are put together as tight-fitting as possible, they will swell and become perfectly water-tight in damp, wintry weather. Three feet wide and seven feet long is a convenient size for use and to handle. Besides mats and shutters, we also use a good deal of sea-thatch for covering up our frames in winter.

It is now generally conceded that for Lettuces, Radishes and other vegetables which we wish to gather every day or two in winter, frames are but a clumsy device, and the alert market gardeners who supply New York City with winter salads are fully awake to this fact. In the neighborhood of Springfield, Jamaica and other parts of Queens County, the truck gardeners have abandoned the use of frames for winter salads and vegetables, and, instead, have erected large ranges of low roofed green-houses, in which they grow their crops with so much certainty and so little trouble, that they are not only able to hold their own against competition with the South, but they regard their green-house winter crops as the most profitable part of their gardening. Progressive florists,

too, are using cool green-houses instead of frames, and they would not do this if it did not pay them. One large grower here is most emphatic in his opinion of the advantage and profit of green-houses over frames for winter work, and the multitude of frames he has cleared away recently, and the multitude of green-houses he has built in their places, is pretty clear proof of his confidence in houses. The vast amount of labor expended in covering and uncovering frames almost every day, the expense of the materials used as coverings, the very much greater wear and tear of frames than of green-houses, the inconvenience of cropping and gathering in midwinter, and the risk of losing a crop by close confinement in a long period of severe cold weather, are disadvantages well understood by practical men. No wonder, then, that the market gardeners and florists, whose bread depends upon their crops, are, on account of keen competition, obliged to give up the laborious, vexatious and unsatisfactory winter-frame for the green-house.

Glen Cove, N. Y.

William Falconer.

Notes from an Amateur's Garden.

THE horticultural experiences of amateurs have usually very little interest for professional florists, who work under different conditions and with different objects. To other amateurs they may, however, be acceptable, even if somewhat trivial in character. From this point of view I offer some brief notices—fruits of my own experience.

Incarvillea Olga.—This plant was introduced from Turkestan by Dr. Regel, and has been much lauded by dealers. In this climate it is perfectly worthless. The flowers have a rose color and come out in slow succession, one opening after another has fallen. As flowers they do not compare for one moment with good Antirrhinums, far less with even ordinary Pentstemons. The plant is hardy here in Newport; its leaves are fine both in color and form, but its habit is bad, as it is not distinctly a vine but yet requires support. The sooner it disappears from the catalogues, the better. Possibly it might yield a valuable hybrid with *Tecoma radicans*.

Montbretia crocosmiæflora.—I find that this fine hybrid bulb is hardy in the light soil of my garden when well protected with leaves or straw. On comparing plants from four bulbs which had been kept all winter in sand in a cold-frame and well covered with leaves, with others which had been left in the open ground but protected as above, I could find no appreciable difference. The horticultural world owes Mr. Lemoine a debt of warm gratitude for the creation of this beautiful plant. Of the seedling varieties which I have seen, Gere d'Or is the finest, a fine, clear yellow replacing the rich vermilion-red of the parent flower. Then the plants yield seeds in the greatest abundance, though they do not always ripen well in our long, cold autumns.

Tritonia aurea.—This beautiful plant has not been rendered superfluous by the introduction of its hybrid progeny. It is not hardy here even with protection, but goes through the winter extremely well when taken up late in October, covered with dry sand, placed in a cold-frame and then covered well with leaves. It may be transplanted to the open border in May, by which time it will have made long, green shoots in abundance. It flowers profusely and for a long time. The other parent of Lemoine's hybrid, *Montbretia Pottsi*, goes through the winter here in the open ground when well covered with leaves. It is pretty, but I think not worth cultivation.

Lemoine's Hybrid Gladioli.—These also are perfectly hardy here when well protected with leaves or straw. My finest plants were grown in a mixture of pure sand and pure leaf mould without manure of any kind. Many stalks were five feet in height. I have begun to hybridize them with *G. Saundersii*, and hope in due time to communicate my results.

Hybrids between *G. Saundersii* and various forms of *G. Gandavensis* were some years ago produced by Mr. Max Leichtlin, but they have never, so far as I am aware, been offered for sale. Of quite a number which I received from Mr. Leichtlin, all but one gradually sickened and died. The one which remains, closely resembles the parent, *G. Saundersii*, but the petals are not reflexed. The flower is very large and fine, nearly or quite four inches from tip to tip of the expanded petals. It has recently been stated in the *London Garden* that these hybrids have also been taken up by Mr. Lemoine, and Mr. Leichtlin's name is not mentioned in connection with them.

Zephyranthes candida.—This very charming and desirable bulb is well known and requires no description in this place. The bulbs do not ripen in our cool autumn, but the plant remains fresh and green till far into November. I find that it

is only necessary to take up the clumps of green leaves and new bulbs, cover them well with sand and put them into a cold-frame well filled up afterward with leaves. In the spring the clumps are almost as fresh and green as when first put into the frame. Transplanted to the open border, they grow freely, and produce their pure white, lily-like flowers in great abundance from about the middle of August until they are again taken up, unless cut down by frost. Few bulbs make so many offsets. Clumps of *Zephyranthes candida* interspersed with *Colchicums* make very attractive beds. In the absence of other bulbs the clumps should be planted quite near each other, so that the fine green foliage may completely cover the ground.

Newport, R. I., October 20th.

Shall We Plant in Fall or in Spring?

THE proper season for planting trees and vines is a question on which people differ materially, some insisting that the fall is the very best time, and others advocate the spring with equal vehemence. Experience leads me to believe that the condition of soil and the subject to be planted has more to do with results than the particular season at which the work is done. Much of the loss is directly traceable to the treatment which the trees or plants receive during the interval from the time of their removal from the nursery until they are planted. I have seen evergreens lying on the ground during the noon hour, with roots exposed to the rays of a blazing sun and drying winds, and I have too often seen choice trees and plants similarly exposed while the so-called gardener was getting ready to set them. No wonder failure follows such treatment. In fact, Evergreens thus exposed had better be thrown on the brush-pile at once, to save the labor of setting and the vexation at the certain loss. The roots of trees and plants of all kinds should be exposed as little as possible and never allowed to become dry. This is especially true of trees and plants having fine fibrous roots, which soon wither and die of exposure in a dry atmosphere; fleshy and woody roots are not as susceptible, and will endure more exposure with less apparent injury.

Another serious cause of failure is the digging of trees and vines before the wood is sufficiently matured. Nurserymen anxious to commence operations in the fall sometimes yield to the importunities of customers and dig trees before the leaves have fallen, in which case they are generally stripped off by hand, entailing extra work. Such trees, especially Peach trees, are often killed if exposed during the winter. For this reason I prefer spring planting for the Peach, unless the trees can be dug and planted late in the fall, after they have fully matured. Fall planting, then, is quite as safe. Spring is, also, the best season for planting evergreens. It is well, in fall planting of trees or even vines, to raise a mound of earth about the trunk, and mulch with a little coarse manure. This course is especially applicable to vines or small plants with superficial roots, for these are much more apt to be lifted out by the action of the frost. The earthing up turns the rain and snow-water away from them, and on ground infested with mice it is a good protection against their attacks. The soluble portion of the manure finds its way to the roots, while the manure itself is a safeguard against the piercing winds and severe cold. This mound of earth should be leveled down in spring, and the manure replaced around the stem of the plant, to serve as a mulch, and keep the ground cool and moist.

This earthing up process is also a good support to the tree in preventing its being swayed about by the winds, although to keep trees erect till established they should be staked and tied. Another advantage of planting in autumn is that there is then less hurry and rush than there is in spring. The ground also can be worked in the fall into a condition not possible to reach in spring, because if it is so wet as to become packed and hard the action of the frost will disintegrate it, while soil in the same condition, and worked in spring, will not become mellow at all during summer. Wet and unfavorable weather in springs such as the last interferes with and often prevents contemplated planting, and hence it must go over till another season, and a year is lost, while if done in the fall a year is gained. Fall is the best season for purchasing, even if the stock is not planted, because, while the assortment is unbroken, the purchaser stands a much better chance of getting the varieties he wants.

In heeling in trees to be kept over for spring planting some sheltered spot should be chosen and care should be taken that the earth is well settled about the roots, leaving no air spaces. If any danger of injury threatens, a few evergreen boughs against the tops will greatly add to the security of the trees.

The careful planter will take but few trees or plants at a time from the package, keeping their roots covered from sun and wind till the last one is in the ground. With due precautions in what may seem unimportant details, the percentage of failures would be hardly worth notice, let the work be done in autumn or spring. The anxiety and desire for quick results as an atonement for past neglect often induces the planter to get extra-sized trees, but unless such trees have been frequently transplanted and are well supplied with fine roots, time is never gained, and trees are often lost. The inexperienced and impatient are slow to learn this fact.

Montclair, N. J.

E. Williams.

Nerine Fothergilli.—This is a gorgeous bulbous plant, and one that requires but a small amount of care and attention, while the fact of its flowering at this season, when so many summer-blooming plants are on the wane, is an additional merit. Many people fail to flower it in a satisfactory manner, but year after year at Baron Schroeder's it is, during the autumn, one of the most conspicuous features. One great cause of failure in the cultivation of these plants is that many people dry them off after flowering; whereas they really make their growth during the winter and early spring, and require all the light they can have at that season, instead of being placed underneath the stage in the vain hope of inducing them to go to rest. Where the plants are in good condition the beautiful, bright, rich vermilion-colored flowers will be now at their best, while the glaucous foliage is also effective. Besides the rich coloring of the blooms, they appear overspread with a lustre like frosted gold, which is remarkably striking. The soil best suited for this *Nerine* is good, fibrous, rather heavy loam, with a little leaf-mould and a liberal admixture of silver sand. These plants dislike being disturbed at the roots, so that they should not be potted unless it is absolutely necessary. Thorough drainage is essential to their well-doing. In the case of plants that are now flowering, they should, when the blooms are over, be still kept in the greenhouse in as light a position as possible, where they may be allowed to stand till about next May, by which time they will be in quite a dormant condition. If they have been well exposed to the light, the bulbs will be plump and hard. Then a very good plan is to turn them out-of-doors and stand them where they will be fully exposed to the sun, such as at the foot of a south wall or in a narrow border in front of a glass structure. Wherever they are put, care must be taken that worms do not enter the pots, for they will play great havoc with the plants, not only destroying the drainage, but also making the soil in such a state that it is absolutely necessary to repot, and this considerably lessens the chance of the bulbs flowering. If they are roasted up in a sunny spot, and only watered about once a fortnight, they will by about the end of July commence to push up their flower-spikes, when they should be taken into the greenhouse or a cold-frame, and those that are showing flower must be from that time watered when necessary. If the spikes are not visible the plants are better if kept dry for a little longer, and if watered too freely before the blooms are seen, a large crop of leaves often results at the expense of the flower. The major variety of *Nerine Fothergilli* is the largest and most imposing of the genus, but all are very beautiful, and well worthy of a little special care and attention.—*The London Garden.*

Soil for Roses.—If not already attended to, it should be borne in mind that a good supply of soil will be necessary for next year's operations in the Rose houses, and that now is the time to secure it, for when stacked up at this season and allowed to remain until needed for use next June or July, it will be found in the best condition for working. The soil, for this purpose, should be a good loam of medium consistency, such as is usually found in an old pasture, from which a layer may be taken about as thick as a spade will cut, including the sod. By medium consistency is meant a loam, not very sandy, nor yet entirely composed of clay. When it is too stiff it requires more preparation to fit it for successful Rose culture, and, also, more careful applications of water and of fertilizers. The sod for this supply should be stacked up in a neat pile, about four feet in height, with some good, short stable manure, in the proportion of one load to six of sod, the latter being placed grass side down, so as to assist the process of disintegration. Rose-growers differ as to the best manure to use for this purpose; but probably a majority are in favor of using that composed of equal parts of horse and cow manure, besides which, many add a small proportion of good bone-meal to the compost, before taking it into the Rose houses.

In some of our large cities, where florists have no sod at command, they resort to somewhat different methods, for while their compost heap may be similarly constructed, they also utilize their old soil by seeding it with grass, so as to prepare a sod for future use. This mode of procedure seems to have some disadvantages. One is, that it must necessarily take a considerable time for this partially exhausted or soured soil to regain its former good qualities; a second and more serious one is, that when the old soil has been taken out of a house infested with the Rose bug (*Aramigus Fulleri*), there is some danger of increasing and perpetuating this formidable pest, from the fact that it has not been positively demonstrated that its larvæ are destroyed by frost, and, therefore, it would seem to be decidedly the safest plan to use only new soil for the Rose bed.

Some experiments have been made to test the hardiness of the Rose bug, but, so far, the result has not been conclusive, and it is understood that further experiments will be made during the coming winter, so that another year will furnish us with more definite knowledge on this point. W.

Philadelphia.

Out-Door Roses.—An Indiana correspondent writes about these as follows: Mrs. John Laing is really a very fine Rose, equal to American Beauty in the number of blossoms it bears,

of a pallid blue. The flower stalk is two feet long and bears from fifteen to twenty flowers. *Vanda Sanderiana* wears a different appearance, having fine, bold flowers from four to five inches in diameter, which last in bloom about six weeks. Cypripediums are out now in great force; the most beautiful at present in bloom are the following: *Cypripedium Parishii*, *C. Stonei*, *C. calophyllum*, *C. tonsum*, *C. Harrisianum*, *C. Fairricianum*, *C. Spicerianum*, *C. Haynaldianum*, *C. marmorophyllum*, *C. Sedeni*, *C. vexillarium*, *C. conchiferum*, *C. purpuratum* (Kimball's variety); *C. Sedeni candidulum*, *C. Roetzlii*, *C. Lawrenceanum*, *C. obscurum*. *C. Spicerianum* I consider the most beautiful of the lot and the most useful, though *C. vexillarium* is a great favorite of mine, and if it were more abundant, it would make a spirited rivalry for the first place. *C. Fairricianum* is a little gem and worth more than its weight in gold, not more than six being in this country. *Renanthera Lowii* (or *Vanda Lowii*), a very rare Orchid, is now in bloom, its long flower spike holding from forty to sixty blooms. This is a remarkable plant, having two dissimilar forms of flower on the same spike—that is, the two flowers at the base of the spike are of a different color from that of the others—which strange contrast gives it a distinct value.

There are a great many other Orchids in bloom in the way of Cattleyas, Epidendrums, Oncidiums, Zygopetalums, Pleiones, or Indian Crocus, Dendrobiums, and

Fig. 71.—*Spiræa trilobata*.—See page 453.

and the average is better in quality. American Beauty is very fine, if budded, but does not succeed with me on its own roots. Lady Helen Stewart and Earl Dufferin have the merit of growing well, but neither of them blossomed with me this season, although they were large plants when set out last spring.

Folkstone comes nearer to La France, as a bedder, than any other hybrid Tea; I like it very much. Puritan, as a failure, is fully equal to Her Majesty. I have tried it now for the second season, and have not yet had one perfect Rose from it. I did not get one perfect bloom on Her Majesty in three years. Nearly all Roses do better for me if budded—that is, if they are budded low, say within three inches of the crown of roots. I have just finished planting fifty newly purchased kinds, most of them being budded; but in more than half of them the bud was at least six inches above the root. As I always, in planting, set the bud three or four inches below the surface of the ground, it will be almost impossible to set the roots of these in good soil.

Orchid Notes.—The most beautiful in bloom now, as the season opens, is *Vanda carulea*, with erect scapes, and flowers

quite a number of botanical curiosities that are very pretty.

Oncidium iridifolium is one of the smallest and also one of the rarest; a beautiful dwarf, about two inches in height, resembling a small Iris in growth, with bright, large, yellow flowers.

Rochester, N. Y., October 30th.

Geo. Savage.

Two Beautiful Stove Bulbs have been in flower lately in the Palm house at Kew, and both deserve attention in private gardens. One is the Ceylon Crinum (*C. Zeylanicum*), a robust looking plant, with a big bulb and long channeled leaves. Its stout flower-stem bears about half a dozen lovely blossoms, with the white petals having a broad crimson band running down the middle of each. Being large, the cluster is very showy, and lasts a long time before fading. The other bulb is *Pancratium speciosum*, than which no flower could be more lovely or more fragrant. It is also a large plant, with broad, luxuriant-looking, evergreen leaves. The flower clusters rise above the foliage, each stem bearing several snow-white blossoms, with long, narrow petals and a web-like cup in the centre. Both plants are easily grown in a

stove, and may be readily obtained from nurseries. It is a pity that plants like these, possessing such wondrous flower-beauty, should be neglected for the sake of novelties not half so beautiful.—*The London Garden.*

Plant Notes.

Spiræa trilobata.

Spiræa trilobata, of which a flowering branch appears in our illustration on page 452 of this issue, has been cultivated in gardens since the very first years of the century. When the graceful, pendulous branches which sweep the ground are wreathed in early June with their clusters of white flowers, few plants are more beautiful or more generally admired. It is a wide-spreading, open bush, which is rarely more than three or four feet high; and it is one of the very best shrubs which can be used on the margins of a shrubbery to connect taller plants with the grass of the lawn.

Spiræa trilobata is a widely distributed plant, being found in Turkestan, Siberia, Mongolia and northern China. It is one of the very few plants which will not be out of place in any collection of shrubs, or in any garden.

Notes from the Arnold Arboretum.

THE most beautiful plant now in this collection, so far as its fruit is concerned, is *Lycium Chinense*, a Chinese species with semi-prostrate or vine-like branches, eight or ten feet long. From these spring, at nearly right angles, rigid, lateral branches, one or two feet long, and these are fairly loaded with bright scarlet, oblong fruits, about half an inch long, contrasting finely with the leaves, which are still bright green and shining. The end of each main branch is, as it were, a broad and leafy raceme, two or three feet long, of brilliant fruit. The fruit and the leaves remain upon this plant until destroyed by really hard freezing. Among fruits which are ornamental at this season of the year should be mentioned forms of one of the Asiatic Apples, *Pyrus prunifolia*, one of the parents, most authors affirm, of the so-called Siberian Crabs. The fruit of *Pyrus prunifolia* is golden yellow on some plants, and bright scarlet upon others. It is an inch or two in diameter, and hangs upon the branches long after the leaves have fallen, retaining its form and its brilliant colors well into the winter. This species, or its varieties—for the so-called ornamental Apples are so changed by long cultivation, and perhaps by the crossing of the different species and varieties, that it is rarely possible to find exactly the wild type of any of them—is far more ornamental in fruit than the more commonly cultivated varieties of *P. baccata*, the fruit of which, distinguished by the deciduous calyx, is smaller, and less persistent upon the branches. The foliage of the Asiatic Apples falls early and without change of color, so that it is for their flowers rather than for autumn effects that these plants are really valuable. But one of the Asiatic Pears, *Pyrus Sinensis*, often known as the Sand Pear, is not surpassed by any other tree in the deep rich scarlet and purple tones of its autumn leaves. This is a plant of excellent habit and rapid growth; it is beautiful when in flower; the fruit has considerable value for culinary purposes, and the leaves turn more beautifully in the autumn than those of any other fruit-tree which I can now recall. It is a tree, therefore, which might well be seen in gardens more generally than it is at present. Another eastern Asia Pear, *P. betulifolia*, loses its silvery white leaves early, and without any change of color.

Few *Spiræas* are valuable on account of the colors of their autumn foliage. Many of the species, especially the European and Siberian, lose their leaves early; but *S. prunifolia*, of which only the double flowered variety is known to botanists or in gardens, one of the least attractive of the entire genus, both in habit and in its flowers, is now beautiful in the brilliant orange and scarlet of its autumn dress. *Spiræa Thunbergii* is still green, but its leaves will turn to rich colors at the end of another week or two. This is almost the very latest to change of the shrubs which take on bright autumn colors, just as it is one of the very earliest of all shrubs to put forth its leaves in the spring, and among the earliest to flower. Few shrubs, all things considered, are more beautiful than this Japanese *Spiræa*, and few can boast of more good qualities. Here its only fault is found in the fact that the ends of the branches are sometimes killed back in severe winters.

Among European shrubs, none assume such attractive colors in autumn as do some forms of the common Spindle tree (*Euonymus Europæus*), although in the richness, or, rather, in the depth of its autumn tints, their American con-

gener (*E. atropurpureus*) surpasses them. Much more beautiful, however, than either the European or the American species in this respect, is the Japanese *E. alata*. Forms of this plant vary here; but there is one in the collection upon which the leaves assume in autumn a clear, rose-pink color, which resembles that of no other plant I can recall, and which makes it one of the most interesting shrubs that can be grown, wherever attention is paid in planting to autumnal effects. The fruit, however, is small, and not to be compared in brilliancy or in beauty with that of the European plants, which are conspicuous objects in the shrubbery through the autumn and early winter months.

We spoke, when the plants were in flower, of the beauty of a Japanese Cherry, *Prunus Pseudo Cerasus*. Its value as an ornamental plant is heightened by the fact that its leaves turn at this season here to orange and scarlet. Among small trees of comparatively recent introduction into our gardens not one gives better promise of real ornamental value. A feeble growth and not particularly good habit are the only drawbacks in this plant, and these are compensated for by its abundant flowers and handsome foliage.

The Japanese Maples are certainly at their best in the autumn, when the colors which some species take on are almost unsurpassed. On the whole, Japanese Maples cannot be considered a great success in cultivation here. Occasionally a fairly good specimen of *Acer polymorphum* or *Acer Japonicum* may be seen, but none of the race seem possessed of very robust constitution, and all of them, although hardy enough as regards cold, are apt to perish suddenly, or branch by branch, without any apparent cause, during the summer. The nearer the plants approach the types of the species, the more satisfactory they seem to be, and the green-leaved and the purple-leaved *A. polymorphum* are more reliable here than any of the abnormal forms of this species, and of *A. Japonicum*, which Japanese gardeners have been collecting and perpetuating for centuries. But Japanese Maples are such really beautiful objects at this season of the year, that one is tempted to recommend their more general use in gardens, in spite of all the disappointments which have followed their cultivation, and of the miserable sun-burned appearance many of the varieties present before the autumn kindles their color into a blaze. A week of such beauty may well compensate for many disappointments.

Few Maples turn more beautifully than the shrub-like Manchurian form of *Acer Tartaricum*, which is sometimes known as *Acer Ginnala*; but it has the serious defect of losing its leaves early and before most other plants have made their finest autumn show.

There is great difference in the behavior of the various species of Lilac in autumn. The leaves of the common Lilac never change color at all, but remain green until very late and then turn black and fall. The Persian Lilac behaves in the same way, while the leaves of *S. Chinensis* turn to a pale yellow, without beauty. The leaves of *S. Japonica* and *S. Amurensis* fall early in October and without changing color, and this is certainly a defect in these plants as garden ornaments. *S. villosa* behaves in the same way, although the leaves persist a few days longer than upon the two species just referred to. The leaves of *S. Pekinensis* remain much later upon the plant, and then turn a light, but not very clear yellow. The leathery leaves of *S. oblata*, the only Lilac worth consideration for the autumn coloring of its foliage, are still green. A little later they will turn to a deep rich claret color of unsurpassed beauty.

Female plants of the Black Alder, *Ilex (Prinos) verticillata*, are now conspicuous objects, covered with their bright red fruits. There is a plant in this collection with yellow fruit, but this is less showy than the common forms, and hardly worth cultivating except as a curiosity. The leaves of the Black Alder turn black before they fall, and without any previous change of color, while on an allied and comparatively rare species, *Ilex lavigata*, which may be most readily distinguished by its stalked fruit, the autumn coloring of the leaves is bright yellow. These two Hollies are well worth general cultivation for the beauty of their fruits. They will thrive, although swamp plants, in any ordinary garden soil.

Some of our native Viburnums are worthy of mention at this time. The most conspicuous, perhaps, although its foliage, having first turned orange and scarlet, has now nearly all gone, is the cosmopolitan *V. Opulus*, the most showy of the genus in fruit, which is large and bright red, remaining for many weeks upon the branches until devoured by birds, who seem to attack it only when other food becomes scarce. The broad and handsome leaves of *V. dentatum*, one of the most ornamental species of the genus in habit, foliage, flowers and

fruit, are now dark bronzy red upon the lower parts of the branches, while those nearer the ends are still green and lustrous. *V. nudum* and *V. cassinoides* are both beautiful in the autumn, their deep green leaves first shading into purple, and then turning to the color of claret wine. *V. Lentago* and *V. prunifolium* are handsome objects, too, at this season of the year, when their leaves have turned from bright green to orange and purple.

There is a great difference in the behavior of the different Roses in regard to the change of foliage. Most Old World species lose their leaves without any change of color at all. *Rosa rugosa* is an exception to this rule. *Rosa spinosissima*, the Scotch Rose, is another, although the colors which its leaves assume in the autumn are not very striking. The species which inhabit western North America lose their leaves without any change of color, while those peculiar to the eastern part of the continent change more or less brilliantly. *R. nitida* and *R. lucida* surpass them all, and there are few shrubs upon which the autumn foliage is more persistent or more beautiful than upon these two Roses. Masses of them, covered with ripe fruit, and fairly glowing with the deep tints of their leaves, are not surpassed just now in brilliancy by any plants in the Arboretum.

The foliage covering the long, wand-like branches of *Andromeda Mariana* is intensely scarlet, while that of *Leucothöe racemosa* is not less attractive, although a large proportion of green is still seen among the shades of red, which in a few days will make this one of the most beautiful of our native shrubs.

It is worth noting, perhaps, that the leaves of *Quercus dentata*, a species of eastern Asia, of much promise here as an ornamental tree, turn bright orange and scarlet, not a very common combination of autumn colors among Oaks; that while our North American Yellow-wood (*Cladastris tinctoria*) is a beautiful object in the autumn, from the bright, warm yellow of its leaves, the eastern Asia representative of this genus loses its leaves fully two weeks earlier without any change of color; and that among the Larches the most beautiful in autumn coloring is the Japanese *Larix leptolepis*, upon which the leaves are now a clear canary-yellow, and much brighter than those of either the American or the European species. The leaves of *Pseudolarix*, one of the hardiest and most beautiful of exotic Conifers, turn to a deep orange hue in the autumn. They fell from the trees, however, several days ago.

October 29th.*

7.

The Forest.

European Forest Management.

WE hear much reference to the excellent forest management prevailing in European countries, and on the other hand, the statement that the application of such management would be impracticable with us, and that we cannot learn much, if anything, from European practice. Both statements, I fear, are mostly made without definite knowledge of the subject and without proper consideration. It would be of interest, therefore, to briefly state what the principal features of European forest management are, and wherein its introduction is unsuitable to our conditions.

We shall have to discern between forest management by the state and by individual owners. The former, which attempts, and, to some extent, represents, an ideal forest management, is carried on upon considerations of the general welfare, of continuity and regularity in material supplies, and upon other considerations of national economy; while the private forest management, imitating mostly the methods of the state forester, works mainly for the highest profits, and only to a limited extent recognizes the desirability of a regular and continuous revenue from the forest. Of course forest management is differently developed in the various states and portions of the same state, according to the general development of the country and its local needs. While in north-eastern Prussia, where forest land abounds and population is not very dense, the management is more or less crude, in the western parts a careful and intensive working of the forest takes place. In general we may say that in Germany, and especially in Prussia, Bavaria and Saxony, the science of forestry is the most highly developed.

The essential features of a well regulated forest management, and the principles underlying European, especially German, state forestry, may be briefly stated as follows:

1. Forestry is regarded as much a business as agriculture; it means the growing of a wood crop.

2. A proper economy in a densely populated country requires that all the agriculturally valuable soil should be, as far as possible, turned to agricultural use; the wood crop is, therefore, the crop with which to utilize the poorer soils; agricultural lands devoted to forest growth are becoming a rarity.

3. A proper economy requires that every portion of the land be made productive; therefore, when the crop is utilized, a new crop is planted or its natural reproduction is secured.

4. Different timbers have a different capacity for reproducing themselves naturally; the natural reproduction is therefore either encouraged or artificially supplied; the reproduction is expected either by sprouts from the stump (coppice), which method is resorted to, however, only for the production of smaller sizes for fire-wood and tan-bark; or it is expected from the seed, when proper preparative cuttings in the old timber must be made, and after the young plants have come up, light and air must be gradually given them by removing the old growth; or, thirdly, after the old growth is removed (clearing) the new crop is sown or planted—generally the latter.

5. Mixed plantations, especially of Conifers, as dominant growth mixed with deciduous trees, have the preference, in planting, for various reasons which it would take too long to discuss here; experience has shown which are the proper mixtures, the rapidity of height-growth and the varying capacity of shade or light endurance possessed by the different trees being the criterion in their choice for mixture. Close planting is practiced, because the shading of the soil, which prevents evaporation, is of prime importance, and because in a close growth, within limits, the trees grow more rapidly in height, or, at least, straighter, forming clean boles, and are not so apt to spread into branches.

6. But few trees—not more than ten or twelve—are predominantly used in German forestry; Pine, Spruce, Fir, Beech and Oak, one species of each, being the principal ones. Contrary to statements made by various writers, the bulk of the German forests—probably fully two-thirds of them—consist of Conifers, and the planting mainly concerns itself with Pine and Spruce. Beech groves are usually reproduced by natural seeding, or more rarely by planting in bunches; Oak is introduced by sowing the acorns or by planting one to three-year-old plants on deeply cultivated plats; on better soils larger plants are used, and for tan-bark coppices often the roots alone are planted. For Pine, the rule is to clear small strips, followed by planting with one and two-year-old (not transplanted) seedlings, after cultivation with the plow and subsoil plow or simple preparation of the soil by the hoe. For the Spruce, also, clearing in moderately wide strips, with subsequent planting, is the rule; but sometimes the reproduction is by natural seeding. For planting Spruce, transplanted plants or else bunches of from three to six plants in a bunch are used—the latter method, however, is losing ground. Larches are planted only as single individuals in intermixture, never in pure growths or clumps, as when so planted, it has been observed that they fail and are apt to die early. The other woods are generally used in admixtures, but occasionally in pure growths on special sites, as, for instance, the Alder in overflowed swamps and the Birch on safety strips along railroads.

7. In the management of the crop, thinning out is the principal operation. Cultivation with the plow to subdue weeds, etc., is rarely resorted to. This thinning is done first when the crop is eight or ten years old, and is then periodically or annually repeated. Farmers get their fire-wood by these thinnings. The object of the thinning is to give more light to the crowns of the remaining trees, in order to stimulate diameter-growth after they have attained a good height-growth. The thinning must never be so severe that the soil is deprived of shade for any length of time. Sometimes when too many trees have been cut out, or under certain other circumstances, it becomes necessary to put in an undergrowth (underplanting) for the purpose of shading the soil; the cleaning out of undergrowth—shrubby; not weeds—practiced sometimes in this country, is a useless if not an injurious proceeding.

8. The annual crop is composed of the annual layers of wood which the trees form each year. As these cannot be harvested, an accumulation of many of them, that is to say, trees of proper size fit for use, are cut, while the younger ones remain to grow on. On large forest areas it is desirable to have annually, or at least periodically, the same amount of cut or revenue. In the state forests, therefore, and those of large estates, these amounts are as much as possible equalized from year to year, or at least from period to period. The ideal equalization may be conceived in this wise. Assuming that the most profitable growth is attained in 100 years, as

may be the case with a White Pine forest, and we have 1,000 acres under management, then we might cut every year ten acres of 100-year-old wood, or periodically during every period of ten years, 100 acres of such wood. After the forest has been brought under this kind of management (which theoretically would require 100 years, although in practice the process is much modified) we should then have a forest consisting of 100 sections of ten acres each, from one to 100 years old, each differing by one year of age, or if periodically treated, ten sections of 100 acres, each differing by an average age of ten years.

If reproduction from seed is expected, we might cull over even a larger area, making our periods longer. But this culling differs from that practiced in this country. Instead of taking out the best trees first, leaving the inferior or less valuable ones, the culling is done entirely with a view of securing a good new growth, and takes the inferior material first; the best trees are rather left to provide the seed and to gain in proportions, making the most valuable material after they are thus exposed to increased light influence, and they are removed only as the young after-growth requires. The adjustment is practically very much more complicated, since in the same forest area some timbers on certain soils will come to their best production earlier or later than the general period of rotation, assumed at 100 years. The small owner, of course, utilizes his crop when it is at the most profitable age financially, and this varies greatly in different localities; but he looks to its proper reproduction by cutting, so as to secure a vigorous young growth from natural seeding or sprouts, or by replanting after the clearing.

9. Neither the firing of the woods or the browsing of cattle in young growths is considered advantageous to the wood crop and strict regulations in this respect are enforced with good effect.

10. The age at which the crop is utilized differs greatly, according to the use to which it is put, the climate and soil on which it is grown and the kind of trees of which it is composed, and the need and profitableness of the market. The coppice is cut in rotations of ten to thirty years, sometimes even forty years; the longest rotations prevail in Alder and Birch forests in the eastern (colder) provinces. For Beech, which forms the most valuable dominant growth of broad-leaved trees, in the timber forest 90 to 120 years are required, the longer rotation in the mountainous localities and in the eastern (colder) provinces. For Pine and Spruce a rotation of from 60 to 120 years prevails (mostly 80 to 100 years), the longest period for the better soils of the eastern provinces, which are capable of producing good building timber. Alder and Birch in the timber forest will be cut in forty to sixty year rotation, and Oak, which is rarely found in pure or extensive growths, but is grown as prominent admixture, is kept over for 140 to 160 years; if "undergrown" in time, sometimes 120 years will produce the desirable sizes and qualities. For tan-bark coppice, it is cut in rotations of ten to fifteen years.

11. Coppice management is practiced in small wood lots and on thin soils, while in protective forests in high, exposed mountain districts a management of culling (or selection) is the rule. The State forests are, as much as possible, managed as timber forest, while small forest owners prefer a combination of timber forest and coppice called "middlewald," which we may render into "standard coppice." In some localities the communities or small owners practice a combination of forest growing and agriculture. After the forest is cut the ground is, for a few years, utilized for agricultural crops, before or even while being replanted to forest; and the economy of this system, with its good results, if properly carried on, will recommend it to our forest growing farmers.

If it is asked, "Is forest growing profitable in Europe?" the answer must be, "It depends;" it depends on what is called profitable and upon the situation. Considering that the European forests are now pretty nearly culled of all their virgin timber and are relegated to the poor soils and waste places, they are probably profitable enough investments.

The German forests, for which pretty reliable data are at hand, yield an annual net dividend of \$57,000,000 from 34,000,000 acres of forest reserve, being considered a three per cent. investment, the soil being valued at \$400,000,000 and the standing wood capital, from which the interest is drawn annually, at \$1,600,000,000. Over a million men find useful and steady occupation during part of the year, at least, and the soil is utilized to its best advantage, with security against the ills of disturbed climatic and hydrologic conditions. Surely, to the nation, forestry is profitable, whatever it may be to the single individual.

Horticultural Exhibitions.

The New York Chrysanthemum Show.

THE experiment of holding this exhibition in a large tent has proved successful in furnishing a better and more evenly distributed light than that found in any of the halls which the New York Horticultural Society has used for the purpose in former years. Besides this, the plants and flowers retain their freshness longer under the cool and well ventilated tent than in the close, dry air of a hall. This is especially true of the cut Roses, which were displayed in considerable numbers and were of the best quality. All the standard varieties were exhibited by Mr. John N. May and Mr. J. H. Taylor, together with the newer favorites, like the Bride, American Beauty and Madame de Watteville.

The display of single cut Chrysanthemum blooms was much superior to anything of the kind ever seen in this city, and, perhaps, the fifty flowers shown by Wm. Tricker, gardener to Judge Benedict, of Staten Island, were the best that have ever been exhibited in this country. This collection was largely made up of American seedlings, many of them comparatively new, and after examining them one could well believe, with Mr. Robert Craig, that the best twelve American seedlings of last year were superior to the best twelve originated in England or France. Mr. Tricker's collection, which won the first prize in competition with another remarkably good one shown by Mr. J. H. Spalding, of Orange, New Jersey, gained much in popular interest from the fact that every flower was plainly labeled. Near these choice specimen blooms was a large collection of Chrysanthemums, cut with long stems and arranged in vases by Mr. John Henderson. They were not entered for competition, but they attracted much attention on account of their fine quality, and gave a striking illustration of what can be accomplished with good garden varieties under good garden cultivation only.

Among the cut flowers were many fine seedlings, but very few were sufficiently distinct to deserve mention as improvements on existing varieties. The beautiful silver cup offered by Mrs. Andrew Carnegie for the best American seedling, was properly awarded to a splendid variety named after her, and shown by Wm. Hamilton, of Allegheny City. The head is of great size, the upper side of the incurved florets being a very dark crimson, and the lower surface of the same color near the base, but turning to "old gold" at the tip. The stock of this plant is owned by Mr. John Thorpe, from whose collection Mr. Hamilton secured the seed. Another fine seedling is Mrs. Levi P. Morton, now owned by Mr. Robert Craig, of Philadelphia, but raised by Mr. Thomas Jones, of Short Hills. It is rosy pink with an open centre and about nine inches in diameter. The florets are tubular at the base, and as they are white on the under side, a distinct zone of white surrounds the disc, which, together with the graceful arrangement of the slightly incurved rays, make a most attractive novelty.

Of the new Chrysanthemums of foreign origin, the one named Mrs. Alpheus Hardy excites the greatest interest. It is exhibited by Messrs. Pitcher & Manda, of Short Hills, New Jersey. It has somewhat changed from its form last year, the hair-like growths on the florets being more thickly set and downy than in the specimen from which the illustration in the first number of this journal was taken. The head seems frosted over with glittering white, and altogether in form and finish it is the most striking variation from old types of the Chrysanthemum that has been produced for years.

Very interesting, too, was a group of nine specimen blooms sent by E. Fewkes & Son, of Newton Highlands, Massachusetts. These varieties came from Japan in the same collection with Mrs. Alpheus Hardy, and they all have distinct merit. One of them, Kioto, is a fine yellow, belonging to the incurved section, but with florets whorled and coiled in a novel way. Medusa, another, has long white petals, so narrow that they can almost be called thread-like, which hang in a disheveled way that certainly is not beautiful. The value of this variety, however, lies in the fact that it is another break into a decidedly novel form, and it therefore gives promise of usefulness in originating a new and distinct strain when crossed with other varieties.

The specimen plants, particularly those which were tied and tortured into artificial shapes, were, as a rule, inferior. Only one or two of the so-called standards had any real beauty. The plants naturally grown, like the half dozen for which Mr. Thorpe received a prize, were altogether more attractive. Those plants, too, which were rooted in summer and carried a single bloom upon stems from one to two feet high, were particularly fine. Any one of them, of average merit, would have been considered a marvel five years ago.

Besides the exhibitors named above, Peter Henderson, Geo. Maclure, John Dallas, of Fairfield, Connecticut, and E. Asmus received prizes. A special prize for a group of Orchids, among which were fine specimens of *Catasetum Bungarothii* and *Cypripedium Spicerianum* was awarded to Messrs. Pitcher & Manda.

The Germantown Exhibition.

A MOST successful exhibition of Chrysanthemums was held in Germantown on the 8th and 9th instant, an ample fund for premiums having been provided by the patrons of horticulture residing there. Parker's Hall was crowded with plants of the best quality. As a rule, they were not so massive as those seen at the shows in Philadelphia, but they were all well grown. Michael Sammon, gardener to Mr. J. M. Shoemaker, contributed three plants, each of which measured four feet across and were perfect in every way. The varieties were Source d'Or, Duchess and Puritan, and the last named carried 450 expanded flowers. The collection of twelve plants, which took the first prize, consisted of General Anderson, Purple King, Shakspeare, Bend d'Or, Cullingfordi, Christmas Eve, Gloriosum, Mrs. G. W. Bullock, Duchess, Mrs. Frank Thompson, Dr. Sharpe and Tokio. They were shown by W. Beasley, gardener to Mr. Benjamin Homer, and they were remarkable for their perfect foliage from top to bottom, as well as for general good culture. Of the numerous seedlings, few, if any, could be considered improvements upon varieties already grown, but two unnamed ones deserve mention. One was in the fine collection of Robert Carey, gardener to Mr. Thos. C. Price, and the second was in that of John McCleary, gardener to Mr. W. Weightman. Both flowers belonged to the Japanese class, the first being pure white and the other yellow. For cut flowers, the first prize was awarded to Joseph Shaw, gardener to Mr. J. Campbell Harris. In the competition open to nurserymen and florists, the principal premiums were awarded to Thomas Meehan & Son and Woltemate Brothers.

J. M.

The Flower Show at Orange, New Jersey.

THE regular fall exhibition of the New Jersey Floricultural Society was held last week at the Rink in Orange, New Jersey, and, as usual, it was noteworthy for the excellent quality of the plants displayed. There was an abundance of Palms, Ferns, Crotons, Marantas, and the like, which were grouped with much taste and skill. The collection of Orchids from the nurseries of Messrs. Pitcher & Manda was unusually rich and varied, containing no less than fifty varieties of Cypripediums alone. The Chrysanthemums in all the classes were the best ever exhibited by the society. The plants trained as standards were commended by the judges as superior to any which have been shown this year. As this was the first exhibition this year of the Chrysanthemum, Mrs. Alpheus Hardy, the flower proved one of the chief attractions of the show and was constantly surrounded by enthusiastic admirers.

The principal prizes were taken by J. Crosby Brown, Geo. J. Ferry, William Barr, E. P. Wilbur, of South Bethlehem, Pennsylvania, Messrs. Pitcher & Manda and John N. May.

Some fine clusters of Niagara and Brighton Grapes were shown by E. & J. C. Williams, of Montclair, New Jersey.

Notes.

A forest fire raged for nearly three weeks in October among the mountains of Santa Clara and Santa Cruz Counties, California.

The proceedings of the Convention of the Society of American Florists, held in New York last August, have been promptly published, and make an instructive volume of nearly 200 pages.

We are sorry to say that the news has just come from St. Petersburg of the death, at Tashkend, of General Prejevalsky, the famous geographer and explorer of Central Asia, to whose proposed expedition into the heart of Tibet reference was made in these columns a few weeks ago.

Experiments at the Amherst College Station indicate that a wash of Portland cement, of the consistency of common paint, will adhere to the bark of young trees during winter, and when mixed with Paris green, will serve as a protection against mice.

Mr. John Thorpe states in *The American Garden* that out of 385 seedling Chrysanthemums raised by him this year, thirty-seven had bloomed before October 18th, and not a single one was worth keeping. The seeds were saved from the best varieties, and yet he can hardly expect five flowers of superior

quality, and will be satisfied if he secures a single one that is a real acquisition.

A curious development of *Lapageria alba* is noted in *The Garden*, of London. A large plant in the green-house at Arundel sent up this year a long shoot from the ground which terminated in a close, umbel-like cluster of more than twenty flowers. The same paper describes a Fig-tree of the Brown Turkey variety, growing at Kingdon Hall, which covers the wall to a height of eighteen feet, and extends fifty-four feet in a lateral direction. It annually bears and ripens a large crop of fruit.

The National Chrysanthemum Society of England has just issued a new catalogue—the third prepared under its direction. It forms a volume of sixty-five closely-printed pages, exclusive of the preface, and includes a historical account of the Chrysanthemum and its introduction into culture. About 2,000 species and varieties are named and described, although novelties of this year's introduction were excluded, as their title to be considered distinct varieties needs further establishment.

The late Professor Edward Tuckerman left a valuable collection of books and papers relating to Lichens to the library of Amherst College, where it will be kept separate from the other collections as a memorial of the donor. The librarian of the college, Mr. W. T. Fletcher, wishes it to be known that supplementary contributions to the collection will be welcomed. And he is in hopes that a fund may be secured to maintain it by additions and repairs. About \$1,000 would suffice for the purpose. Professor Tuckerman's collection of Lichens, unrivaled in North American species, and containing, of course, all his own types, has been acquired by Harvard College through the efforts of our associate, Professor Farlow.

At the Iowa Experiment Station some interesting observations have been made on the different varieties of Indian Corn, from which the conclusion is drawn that those which have a large number of blades on the points of the husks are the more fruitful, probably because this extra leaf surface enables them to assimilate a larger proportion of plant food. It also appears that the leaves of the various kinds show marked differences in the relative amount of chlorophyll-bearing tissues. Other things being equal, it is probable that the power and quality of the leaf for food assimilation depends upon the amount of available chlorophyll it contains, and therefore a microscopic examination of the leaf-structure of any variety will be a help in estimating its comparative value.

The trade in Christmas-trees and greens grows larger year by year. Thirty years ago a Christmas-tree was seldom seen except in some home of the richest class, and the adornment of churches for the festival season was confined to the Catholic and Episcopal denominations. But the immense increase of our German population has popularized the Christmas-tree throughout the length and breadth of the land; and with the waning of old Puritan ideas the decoration of churches of all denominations has become customary. The extent to which materials for these purposes are now required is shown by the fact that a single dealer in New England last year disposed of 10,000 Christmas-trees, 25,000 yards of wreathing and 800 barrels of evergreen spray. The smallest trees that are sold bring, on the ground, ten cents apiece, while the largest—twenty-five to thirty feet in height—bring from \$4 to \$6.

French papers have recently contained summaries of the report of the Minister of Agriculture, Monsieur Viette, upon his tour through the wine-producing departments of France. Of the departments of Hérault, Gard and the Gironde, he says that the flooding of vineyards has had admirable results, and that renewal of the vines by means of grafting upon American species as stocks has proved successful. Grafts of French vines upon American stock have the advantage, it is claimed, of ripening their fruit earlier, and of being more productive without loss of delicacy in the fruit. After long experiment the way has been discovered to renew a vineyard in three years, if the necessary preparations are made. In Hérault this has almost everywhere been accomplished, and in Gard it is rapidly progressing. Vines planted in sand cover wide expanses, and everywhere an excellent harvest is expected. Hérault, which produced seventy-five million gallons of wine last year, is expected this year to produce more than a hundred millions, while forty-five millions are anticipated from the Gironde. Mildew as well as the phylloxera is being successfully combated, and now, it is affirmed, the problem of viticulture has been mastered, from the cultivator's point of view. Economical questions alone remain for adjustment. A strict enforcement of the rules for the inspection of foreign wines on the frontier is recommended, as well as new regulations to control the manufacture of wine from grapes that are not fresh.

A Novel Project for a Public Park.

THE Park Commissioners of the City of Buffalo, in this State, having been asked by the Common Council to consider the practicability of forming a park upon a given site south of the town, have obtained the opinion of Messrs. F. L. and J. C. Olmsted, landscape-architects, upon the question. This opinion, in the form of a pamphlet illustrated with small sketches and accompanied by a plan, gives a definite and remarkably original and interesting form to the project.

It is needless here to summarize the reasons given by the authors why Buffalo should have another park, or why the site in question should be selected. As they show, it is an extremely discouraging spot, from the ordinary landscape-gardening point of view, but it has certain distinctive advantages, and it seems to be proved that there is no better site available, and that a way to adapt this one can be found which will make it both useful and attractive.

The site borders upon Lake Erie and the unobstructed view of the water which it will offer is, of course, a fact of almost priceless value in its favor. It can be reached from the heart of the city by navigable water and by four lines of railroad already in operation. No buildings or cultivated grounds of importance exist to make its acquisition costly, nor is it fitted for agricultural use. But, on the other hand, the surface is quite flat over nine-tenths of its area, and shows no rocks, trees or other valuable natural features. It lies but little above the surface of the lake, and is, conse-

quently, half-swampy and liable to be submerged at seasons of high water. The gravel beach and low shifting sand dunes that edge the lake rest upon a stratum of black muck, which is constantly washed out, and thus the shore is rapidly wasting. And no facility for the landing of visitors from boats is supplied by nature.

Turning now to the plan, which we reproduce on page 463, we find that it is proposed not merely to conquer the natural disadvantages of the site, but actually to base the scheme upon them. The main tract, lying between the shore and the railroads already referred to, is about 240 acres in extent, and nine-tenths of it lies below the level of the lake at high water stages. At its western extremity, however, along the lake, there is a considerable piece of ground which lies several feet higher, and another high strip runs along its southern boundary, while the railroad embankment protects it on the east. Thus it can be flooded only from the northern and from a small portion of the

western side. Here it is proposed that it shall be protected by a levee four and one-half feet high, along which, on the northern side, a tree-planted street may be carried.

The high tract towards the west is to be planted as a green, forming a park-like expanse of turf, about twenty acres in extent, with groups of trees about it. This will afford an excellent playground, and near by will be an athletic ground, with running tracks and other facilities for exercise, three acres in extent. A road for general traffic will cross the park from north to south between the green and the athletic ground, and it will be encircled by drive-ways, with ample spaces for the congregation of persons on foot and in vehicles where the roads approach Lake Erie.

The remainder of the tract in question, about 120 acres of flat and swampy land, is to be turned into a lake with very irregular borders, dotted with islands and promontories. To effect this, it will suffice that the ground shall be excavated in certain places and the soil taken from these heaped upon the remaining portions, while water from Cazenovia Creek is drawn into the excavations, flooding them to the desired height and then passing out into Lake Erie, thus insuring perpetual renewal and freshness. The largest island will be connected with the shore near the north-east corner of the park by a little foot-bridge and is intended to be used for picnics. Its surface will be four or five feet above the water level and planted with shade trees surrounding open spaces of turf. Three smaller islands, which can only be approached by boats, will be reserved as picnic-grounds for private parties who may wish to hire them. And upon still smaller ones it is proposed to breed aquatic birds and grow interesting plants, their shores being protected from disturbance by spaces of shallow water.

Of course, all this implies a park where boats will be the chief means of conveyance. But, as the report explains, this fact by no means militates against the wisdom of the project, for, in all cases where similar schemes have been adopted, their success is emphatic. At Stockholm, for example, and in our own country, at Detroit, there are parks accessible only by boats, yet they are quite as generally used and approved of, as any which have a more usual character. In the case of the Buffalo park ample facilities for walking and driving are provided, but it is believed that its boating facilities may prove its greatest

attraction. To secure these it is proposed to build an artificial haven on the shore of Lake Erie—two parallel piers extending outward to a point on the lake, where at low water a depth of seven feet exists. It is expected that the existence of these piers will cause a sand-bank to form on their southern side, and, supplemented, perhaps, by a wall, will protect the shore from further wasting. In this case, a good beach for surf bathing will be secured, and, on its inward side, facilities for still-water bathing in the artificial lake can be provided. The piers will admit of the approach of steamers of sufficient size coming from the city, and the passengers they land can thence make the circuit of the park on foot or in carriages or by means of boats. For the latter purpose it is intended that row-boats shall be provided, and also public packet boats, in the shape of steam or naphtha launches, which will successively make the tour of the lake, landing passengers where desired. This tour, owing to the winding nature of the water-passages, will be nearly four miles in length.

On the eastward side of the railroad tracks it is thought that, should the state authorities agree, a rifle-range may well be established. A new one is needed in the vicinity of the town, and its association with the park would be a great advantage to those who would use it. In the winter the range could be flooded for skating, and toboggan shuttles put up near by, while there is ample room beyond it for all the accessory buildings that would be required.

Thus the proposed park would be not merely a pleasant resort, but a great and varied public playground, including many features which we have no space to note. The extraordinarily skillful way in which, in other works, Mr. F. L. Olmsted has united usefulness and beauty, is one of his highest and most peculiar titles to respect as a landscape-architect; but his talent in this direction has never been more clearly displayed than in the present scheme. It seems as though no out-door amusement in which modern youths and men indulge had been forgotten; yet all are provided for without injuring the beautiful effect which such a park ought to have. Nothing could be prettier

than the effect we may predict for this scheme, if it is as well carried out as it is now sketched on paper. The greatest variety in outline, disposition and planting will be aimed at in the arrangement on the main shore and the many islands. Each rod of the four-mile water journey will reveal new combinations of water, land and foliage, while the views from the green, with the varied scene to the eastward and the broad expanse of Lake Erie to the westward, will be of unusual charm.

Of course the beauty of the intended result would not fully reveal itself at once, for time must be allowed for trees to grow where to-day there are none. But how much intelligent planting can accomplish in a very few years, we showed not long ago when we illustrated a portion of the park that Mr. Cleveland recently designed for Minneapolis, and in all such schemes ultimate excellence rather than immediate effect is naturally the prime consideration. Of course, too, this would be a costly scheme to execute; but its projectors show that it would not be too costly for the consideration of wise city-fathers, either as regards the expense of actual construction or the future annual expense of maintenance. From the artistic point of view the idea is one that we cannot help desiring may be put in execution; for its intrinsic interest is great, and an idea of just the same kind has never before been car-

ried out by a landscape-architect. And, from the material point of view, there ought, in a city like Buffalo, to be no serious objections made.

In a separate report the Messrs. Olmsted discuss the question of the driving approaches to the proposed South Park; but as the subject could be clearly understood only by those familiar with Buffalo, it does not seem advisable to refer to it here. Our illustrations presenting views in the proposed park as well as the plan, are reproduced from the Messrs. Olmsted's report, and they serve to show how attractive a park of this character might be made.

The manufacture of the oil of sassafras is becoming an important industry in some parts of the country, especially in the Southern States, where this tree is common. Only the roots are used; they are chopped up into small pieces by a machine constructed for the purpose, the oil being then distilled from the chips by the aid of steam. About one gallon of the oil, weighing nine pounds, is obtained from 1,000 pounds of the chips. The uses for which the oil of sassafras can be employed are numerous and varied. It is a favorite perfume for soaps and candies; it is used as a solvent for different gums, and as a liniment. It is also very largely employed in the manufacture of several popular proprietary medicines. The importance of this industry may be expected to increase rather than diminish, as the Sassafras and the Persimmon are the two trees which are spreading most rapidly over the old and abandoned fields throughout the Southern States outside of the Pine Belt proper; and at present prices good wages can be made by digging out the roots.

Double Stocks.

MANY are the theories that have been promulgated as to the cause of the production of double flowers, but few indeed have been the practical experiments made with a view either to confirm or confute the assumptions that have been so freely made. But now we find a record in the *Journal of the National Horticultural Society of France* which bears so directly on the point, that we shall be doing our readers a service by calling attention to it. The record is taken from one of the reports of the German agricultural stations—institutions practically unknown here. The report in question bears the name of Dr. Nobbe—a sufficient guarantee of the credit that may be assigned to the experiments.

At the outset the point is clearly raised by the inquiry as to the reason why seeds of herbaceous plants, improved by cultivation, show a tendency to produce double flowers? Is there any appreciable relation between the nature and condition of the seed and of the flowers which result from their development? In the horticultural department of the experimental station at Tharand an attempt has been made to find an answer to these queries. For this purpose the common stock was selected, as completing its development in the course of one season. Twelve distinct varieties were selected from the establishment of M. E. Benary, of Erfurt. Of each of the twelve varieties 100 seeds, as nearly alike as possible, were chosen. These seeds were placed in Dr. Nobbe's germinating apparatus, and submitted to a continuous and uniform temperature of 20° C. (= 68° F.). After four days some of the seedlings (which must have germinated at once) were removed from the apparatus, and placed in the open ground. The other seedlings, which came up after four days, and between four and nine days after the commencement of the experiment, were thrown away, so that the seedlings reserved consisted of two classes—one in which the germination had been accomplished within four days, and the other those in which germination was not appreciably commenced till after the ninth day. We need not give in detail the arrangement for the accurate comparison of the two sets of seedlings—suffice it to say that the seedlings were eventually transferred to large pots, and placed side by side, half of the pot being occupied by those of slow growth, the second half by the quickly developed seedlings. Moreover, some of the two sets of seedlings were placed in large, others in small pots; some in sterile, sandy soil, others in rich soil, care being always taken to make the experiments rigidly comparable. In all, nearly 600 seedlings were thus under observation. In each case the time of the first appearance of the flower-bud was duly noted, and the period when the first flower opened.

From the large mass of statistical details so obtained the general result was arrived at, that for each variety the period of time between the sowing and the appearance of the first flower-bud was long in proportion to the slowness of germination. In some cases an interval of five or six days was noticed between the seedlings of the two categories. The vigor of the plant was uniformly superior in those cases where the germination was rapid, and, moreover, when subjected to analysis, the amount of dry matter as distinguished from water was always greater in the quickly than in the slowly developed plants.

But the most remarkable results are those relating to the production of double flowers. In all the varieties the proportion of double flowers was greater in the case of those that germinated quickly than in the case of the laggards. Ten plants of one variety with violet-brown flowers, grown rapidly, produced all double flowers, while eight plants of the same variety, which had germinated slowly, produced all single flowers. The following figures convey other striking illustration of the facts now mentioned. Of one hundred plants belonging to nine different varieties, the proportion of double flowers, according to the period occupied in germination, was as follows :

	Doubles.	Singles.
After rapid germination.....	82.56	17.44
After slow germination.....	27.03	72.97

It may be suggested that the superiority might be attributable to the varying influence on the same seeds of light, heat or moisture ; but the experimenters reply that the tendencies exist in the seeds themselves, for the two categories of seedlings were exposed to identically the same conditions, and yet showed the differences already mentioned. Moreover, although those seedlings which were grown on in sterile sand were much less vigorous than those grown in good soil, they, nevertheless, showed corresponding inequality as regards their flowers. Again, next to never was a single flower found in the spikes, bearing from ten to thirty double flowers, and conversely.

Lastly, hybridization shows that the seeds contain in themselves, unaffected by other conditions, the essence of what will be manifested in the plant later on. It must be added that there is in each variety a special tendency to produce double or single flowers, as the case may be. There are some which, however treated, never yield any but single flowers, while others produce almost, or quite exclusively, double flowers, and are, in consequence, doomed to disappear.

These results are so striking that we cannot but think our great seedsmen will repeat the experiments in due season, and avail themselves of the valuable information thus placed at their disposal.—*Gardeners' Chronicle*.

Entomology.

The Red Mite on Trees.

IN the second number of this journal (p. 30) Professor A. S. Packard has a note on "The Red Mite on Verbenas," in which he describes the character of the injuries committed by this minute insect, and gives a summary of the most efficient remedies known. It is usually considered and spoken of, by gardeners and horticulturists, as being most troublesome and injurious to plants in green-houses and conservatories, and occasionally to shrubs, etc., growing in the open air.

With the exception of the two instances quoted below, I do not know of any record of its injuries to large forest or shade trees in this country.

In Europe it is mentioned by several writers as attacking the Linden. In "Economic Entomology, Aptera," by Andrew Murray, those found upon the Linden are given under the name of *Tetranychus tiliarum*, and they are said to "occasionally occur in such numbers as almost to denude the trees of their foliage."

During the past summer, and also in 1887, I have found these little pests attacking, and quite seriously injuring, the foliage of large trees in the Arnold Arboretum, and on the parks and streets and other places about Boston.

The White Oak (*Q. alba*) seems to have suffered more than any other, but all Oaks, both native and those that have been introduced from foreign countries, have been more or less attacked. Those trees with very smooth, shining leaves seem to be least liable to injury, but by no means exempt, as the foliage of *Quercus rubra*, *Q. coccinea* and others very often showed too well. I have found the mites living almost ex-

clusively on the upper surface of the leaves of all the Oaks, spinning a very slight web, which is almost invisible, but the existence of which may be proved by brushing the leaf with a camel's hair brush and thus accumulating the webs. In some instances a few were found on the under side of the leaves, but these seemed to be stragglers.

The effect of their work on the Oak is to give the foliage a general dusty aspect, the leaves become yellowish or grayish above, with lighter patches here and there, and they are frequently so much injured as to become twisted and turned, as if scorched. On some Oaks, such as *Q. palustris*, the leaves become of an even, dull, ashy color all over the upper surface.

It should be stated here that the blotched yellowish or dusty appearance of the Oak leaves is not always entirely produced by the red mite, but is very often caused, either independently, or with the assistance of the mite, by a hemipterous insect, *Corythuca arcuata*, which may be found on the under side of the leaves, from which they suck the sap with their slender beaks. The delicate wing-covers are flat, meshed and scale-like, of a white color, with a dark band across the base and another at the tip, but the dark spots vary in different individuals and are sometimes very faint or entirely lost. The body is black and the largest specimens are about one-sixth of an inch in length. They usually feed in groups, causing the opposite upper side of the leaf to become gray or yellow. On very many Elms the foliage has had a dusty, grayish look, which, upon close examination, has proved to be the work of vast numbers of the red mites living upon both sides of the leaves, but, generally, most abundant on the lower surface.

They live chiefly on the under side of the leaves of the Maple, which either turn an even yellowish gray or become thickly dotted.

They are to be found on the Linden, Ash, Locust and other shade trees, and on the Apple, Plum, Cherry and Peach. The amount of damage done to these trees has not generally been serious enough to attract much attention, but I have seen vigorous young Plum trees lose all their leaves during the month of August, entirely owing to the work of myriads of red mites upon them.

I have found them in large numbers on the American and European Larches, on the Hemlock (*Tsuga Canadensis*), and also quite common on Arbor-vitæ, Spruces, Junipers and White Pines. The foliage of the Larch assumes a dead, brownish appearance when seriously attacked, while the leaves of the Hemlock become of a dull ashy or dirty white color.

In the *American Entomologist and Botanist*, April, 1870 (Vol. 2), p. 180, Professor C. V. Riley says of the mite: "It is best known in the green-house, but likewise does much damage in dry seasons on trees (especially evergreens) in the open air. It thrives best in a dry atmosphere, and we have found no difficulty in getting rid of it by a free use of its natural enemy—water. If a little soap is mixed with the water it will be more effectual."

In the "Fourteenth Report of the State Entomologist of Illinois" (1884), p. 117, Professor S. A. Forbes says: "In June the foliage of the Larches in the grounds of the University at Normal, were seriously affected by the red spider (*Tetranychus telarius*, L.), some of the trees seeming likely to die. On one of those worst infested we tried the effect of spraying with kerosene emulsion made with soap and diluted to contain two and one-half per cent. of kerosene. The insects were greatly reduced in number by a single application, but not all killed. The trees soon revived appreciably, as compared with those not treated."

In examining the mites on different plants, I find that there seems to be a marked variation in their color on some kinds of trees and shrubs. In most cases they are of the typical brick red color, varying in intensity on different plants as well as in the age of the mites. These are usually described as light yellow when young, becoming darker as they grow older.

Some of the Elms on Boston Common and the streets of the city were very badly infested, and, in some cases, almost completely defoliated, during the latter part of the summer, by this or a similar mite, which seems to be of a yellowish green color in all stages of its growth.

At least, on several young trees, from ten to fifteen feet in height, which were literally swarming with mites, so that even the limbs and trunks were covered with their fine web, I was unable to find any specimens of a decidedly red color. Those found on the Butternut were also pale yellowish green. On the White Ash (*Fraxinus Americana*) they vary considerably

from the type in color and in the greater amount of web spun. They are yellow, inclining to orange, with what appear as dark spots, of varying size, on the body, but which is probably the food within seen through the transparent skin. Whether any of these variations may constitute separate species or varieties remains to be determined by some specialist.

The past season has been unusually damp and cool, yet the mites have been very abundant, and have shown remarkable hardiness and tenacity of life in prolonged cool and wet periods. Dry seasons are said to be most favorable to their increase, and, if this is so, they may yet prove a serious annoyance to the landscape-gardener. Trees with very thick, tough leaves, such as the Oaks, may be able to withstand their attacks without showing material injury, but the effect produced is certainly not pleasing from an artistic point of view.

Arnold Arboretum.

New or Little Known Plants.

Berberis Fendleri.*

THE common Barberry, which is so abundant in many places, especially on the hills of New England, though not a native, is our best known representative of the true Berberies. Its bright foliage and not ungraceful habit, its usually abundant, drooping racemes of yellow flowers in spring, and its still more conspicuous bright red berries in autumn, make it decidedly ornamental. Our native species resemble this very closely in most respects. *Berberis Canadensis*, not at all Canadian, as its name would indicate, is confined to the Alleghanies, and is common on stream-banks from Virginia to northern Georgia. The leaves are paler than in *B. vulgaris*, and somewhat glaucous, the flowers are smaller and in much shorter racemes, or nearly corymbose, and the fruit is shorter and more oval or almost globose.

The *B. Fendleri*, of which a figure is given, belongs to the more southern portion of the Rocky Mountains. It was first found by Fendler forty years ago in the mountains near Santa Fé, and has since been collected a little farther to the east on the upper Pecos, northward near Taos, and at the forks of the Rio Grande in southern Colorado. It is of rare occurrence within this limited range. The true Berberies, therefore, which in the Old World extend across the continents of Europe and Asia from England to Japan, are restricted in America to two small mountain districts on the eastern side, being replaced in the west and south-west by the Mahonia section of the genus, and reappearing in South America as evergreen shrubs, of which the cultivated *B. Darwinii* is an example.

The leaves of *B. Fendleri* are green and lucid, while the stem and branches are purplish and shining as if varnished. The flowers are as large as in *B. vulgaris*, in racemes an inch or two long, and at the base of the calyx are a number of smaller, but conspicuous, red bracts. This species flowered in the Botanic Garden here in 1880.

The Vegetable Garden.

THE two great dangers which threaten vegetables that have been lifted and stored early are too much moisture and too much protection. They should be kept dry overhead, cool and well ventilated. Cauliflower, planted out about the 1st of July, is now in full head, and another crop, set out from pots about the end of the month, is showing flower; that planted after Potatoes early in August is later, but the appearance of the hearts gives promise of heading soon. As frost injures the hearts of Cauliflower, in the case of well-developed heads we break a few of the outer leaves and bend them over the hearts to protect them; undeveloped heads are so encircled with leaves as to have protection enough. But it is unsafe to trust Cauliflowers out-of-doors after this time of year, and we are now lifting and storing it in cold-frames, to be covered with sashes, mats or thatch as occasion requires. In preparing these frames we are particular to have them in a sheltered situation, to save covering in winter; and we make the pit two feet deep at the back, and eighteen inches deep

*B. FENDLERI, Gray, Pl. Fendl., 5; Rothrock, Wheeler's Rep., vi, 60.

at the front, banking it with the earth removed from within the frame. The plants are then lifted, stripped of their rougher outside leaves, assorted according to their stage of growth, and planted closely together in the frame. As the heads may not have room enough if the plants are set perfectly upright, the stalks are made to lean, the several rows overlapping each other shingle-fashion. By assorting and storing according to their ripeness, we may begin at one end of the frames and cut clean towards the other, and avoid picking out a head here and there as it matures. And this lessens labor in covering. Late Cauliflowers—that is, plants just showing signs of heading—will, when treated in this way and protected from frost, develop flowers during the winter, and be ready for use in January and February, and sometimes continue till March, when they are highly appreciated. The Erfurt—and some of its varieties, Snowball, for instance—are the best kinds we have this year. Leonormand's and Algiers have not given as good satisfaction as they once did. About Riverhead, in Suffolk County, where Cauliflower is grown in large quantity for New York City markets, the Erfurt has come to be the main crop cultivated.

Brussels Sprouts are much harder than Cauliflower, and we leave them out-of-doors till severe winter weather is likely to set in in December, then we strip off their rougher leaves, lift and heel in the plants close together in a pit, shed or cellar, where they can have light and be kept cool. They usually grow so tall they are awkward to store in ordinary cold-frames. We also have good success with them by lifting and heeling them in quite close together in a warm, sheltered spot out-of-doors, and where we can conveniently construct about them some sort of a temporary shelter—of evergreen branches oftenest.

Cabbages we leave undisturbed so long as there is no danger of the ground freezing hard, say till about the end of November, and often December. We winter them in several ways: The mature ones, with heads down and close together, in out-door trenches; somewhat younger ones, with heads up and stored in frames after the manner of Cauliflower, or with heads up and close together in a shed or cool cellar, or in a bed outside six feet wide, and covered over with some sea-thatch, Oak leaves or evergreen branches. When stored outside we cannot always get them in winter, and therefore for every-day use it is more convenient to have some in a cellar, shed or frame. When packed together with heads up they are apt to grow a little in winter and burst open, but this does not happen when they are bedded with their heads down. Flat Dutch and All Seasons are capital late Cabbages, and the Drumheads are good, but sometimes a little coarse. The Savoys are the finest of all Cabbages for family use, and they are as easily grown as are the plain-leaved Cabbages. The Drumhead Savoy is the variety mostly grown for winter work.

Curled Kale is a capital winter vegetable, and easy to handle because it is very hardy, and half-grown plants are as good as mature ones. Kale can be grown as a catch crop any time after July. Extra Dwarf Curled Erfurt is the finest variety I know. It really is dwarf, much curled, and hardy. Many of the so-called Extra Dwarf Curled Kales have umbrella-heads and stems two feet long. About the end of November lift and replant closely, and when the ground freezes throw a few dry Oak leaves about them, and over these some evergreen branches. The Kale is always better for use after sharp frost; but sunshine and cutting winds in winter need to be guarded against, as they burn the curly leaves.

German or Siberian Kale, like Spinach, is usually sown in September in rows twelve to eighteen inches apart for use as greens in spring. After the surface of the ground is frozen an inch or two deep give it a slight mulching to protect it from sunshine, wind, very severe cold, and from being heaved out of the ground by frost in winter. Mulching before the ground is frozen over only invites field mice, which are very destructive to all covered crops in winter.

In this latitude part of the Celery crop should be stored some time in the latter half of November, according to the weather. Where several thousand heads are kept over out-door trenches or ridges will answer, but where only a few hundreds are to be wintered they should be stored in a shed or cool cellar. When the winters are severer than they are in New York, large growers have regular Celery sheds. For out-door wintering dig a long, deep, narrow trench in a sunny and well-drained space, say twenty or twenty-four inches deep and nine inches wide. Then lift the Celery, keeping all of one sort and all of the same size or earliness together, and stand the plants in these trenches in a single row, but as close together as they can be packed, filling in the soil and packing it firmly as the storing proceeds. Before storing, all sprouts and diseased

leaves should be removed from the heads. Never touch Celery to earth it up or to store it when it is wet or frozen. If one trench is not enough to contain the supply, prepare another alongside of, and about nine or ten inches distant from, the first one, and fill up in the same way. We run four of these trenches on one ridge, which is some seven to ten inches high in the middle, so as to throw off the water readily. We protect these ridges from frost with board coverings, and in severe weather use leaves, litter or thatch as an additional protection over the boards. As it would be impracticable to open these trenches every day in winter for a few heads of Celery, they should only be opened occasionally, and then a two or four weeks' supply taken out at a time, and brought into the cellar and stored upright in a prepared bed in a corner, or in boxes or halves of barrels. Celery is fairly hardy, and should never be covered too thickly. Never mulch the ridges till they first have a thin coating of frosty earth over them, and apply the mulch a little at a time rather than the full amount at once. Snow is a warm covering, but when a heavy coat of snow begins to thaw, shovel it off of the ridges, for snow-water is very penetrating, and the Celery must be kept dry.

Use the White Plume and Golden Self-Blanching first, then whatever kinds are now most blanched, leaving the red-tinted and green Celeries for latest supply. For all purposes we have nothing better than Golden Heart.

Glen Cove, N. Y.

Wm. Falconer.

When and How to Prune Grape Vines.

NOTWITHSTANDING all that has been said and written about the numerous systems of pruning and training the Vine, few operations of the garden are practiced with so little intelligence. Many professional gardeners need no instruction in this matter and others are above receiving it. But to amateurs and novices it may be well to say, that the chief point to remember is, that the cane producing fruit next year is grown on this year's cane.

Fig. 1.

February was formerly considered the best time to prune Grape vines, but of late years fall pruning has rapidly grown in favor, and November is now chosen for this work by expert vine-dressers. The milder weather that is apt to prevail and the absence of snow make it far more comfortable for the operator, and vines that have been overtaxed and failed to mature their fruit can be treated with better judgment when their condition is fresh in the owner's mind, than if the work is deferred till February, when their condition may have been forgotten.

Another reason for fall pruning is, that the removal of surplus wood allows the vine to devote all its energies to more thoroughly ripening the remainder. The maturing and hardening of the wood is not complete when the leaves fall, neither is all wood apparently ripe sufficiently so to pass the winter uninjured. This winter killing of the young and immature wood is the strongest argument in favor of winter pruning, its advocates claiming that no mistake can be made then, as all wood that has safely passed the winter up to that period will continue to live. This is true, but the loss of any wood after pruning is generally too insignificant to be worth considering.

Unless these canes have attained a diameter of three-eighths of an inch or more, they should be cut back and the process repeated till they acquire that size. Vines thus treated will make canes of much greater value than if they had been allowed to grow and had been left to themselves.

The lateral branches that start on these canes should be shortened in to one leaf as they appear, thus forcing the energies of the plant into the main canes.

The vines are generally ready for trellising and training on any system that is decided upon the second season after

planting and may be allowed to bear a bunch or two of Grapes. Many persons are so anxious for fruit that they allow the young vine to overload itself and thus receive a check from which it often takes years to recover.

The vigor and growth of vines vary so widely in different varieties that some require closer pruning than others, and it is on this point that intelligence and judgment are needed.

Fig. 2.

Short pruning gives increased size and fine clusters in a small space. Doubling the space may result in doubling the number of clusters, but not the weight of the crop.

The ground where vines are planted should be naturally dry or made so by drainage, and sufficiently fertile to insure a good growth. Those who have doubts on this point often propose to dig in plenty of stable manure, to which I say, No! unless it is thoroughly decomposed. Otherwise put it on the surface as a mulch and the fertilizing properties will find their way to the roots. Coarse or fine bone can be placed in direct contact with the roots without injury, and almost any of the standard commercial fertilizers may be worked into the soil at planting time, but unfermented manures should be placed on the surface.

The best vines to plant are those one and two years old, the roots of which should be shortened in to about ten inches

in length. When older vines are wanted by impatient people they should have been transplanted yearly, so as to be supplied with well branched fibrous roots, which this shortening in process secures. Such vines, properly planted, will bear a full crop earlier than the younger ones, but, in two or three years, the latter will overtake them. A stake should be set with every vine, and one, or, at most, two shoots, allowed to grow the first season; they should be tied to the stake at intervals.

What is known as the Kniffen system of training, and its improvement, are the simplest of any I have ever tried, and they have, therefore, become more widely adopted perhaps than any other.

The cut (Fig. 1) illustrates the system at a glance. The vine on the left shows the original idea, pure and simple; that on the right the improvement, which consists of growing two trunks, from near the ground. The sap being divided

Fig. 3.

there, each head must get its allotted portion, while in the other case the upper head would be apt to get the lion's share on account of its tendency to flow to the highest point. The arms, which are renewed every year, being in a horizontal position, the buds start with more general uniformity than if they were more upright. The trellis is inexpensive, and is adapted to vineyard or garden. In the latter wood slats can do duty instead of wires.

Fig. 2 gives a view of a vine as it appears before pruning, and Fig. 3 the same vine after pruning. The canes forming the arms are the ones nearest the trunk of the vine, and are cut from five to eight buds long. If longer the buds nearest the trunk would be apt to start too feebly, and fail to acquire sufficient vigor for next year's arm; but if only five or six buds long, a very uniform growth is obtained. By stopping the growth of these young canes at the second or third leaf beyond the last cluster of fruit, the size of the cluster and canes is increased, and the base buds are fully developed, so that the one nearest the trunk generally makes as good a cane, and produces as good clusters as those farther away; and the fruit year after year is kept in a small area near the trunk of the vine. The chief objection to the system is that the wind and rain will sometimes break off the tender shoots while young and growing rapidly. To prevent this I have used an extra wire six inches above the arms, to which the young canes are secured, thus preventing any loss from this cause. I have taken this fall from single vines thus trained from twenty to thirty pounds of fine fruit, which satisfies me entirely as to quantity.

Montclair, N. J.

Rose Notes.

AMERICAN BEAUTY.—The strong growth and upright habit of this Rose make it conspicuous when planted out in the same house with other varieties. On good, healthy plants of this variety the shoots will often attain a height of six to eight feet, and usually terminate in one very large bud, the latter having taken a good while to develop, but generally proving to have been well worth waiting for. After this terminal flower has been cut, it has been found best to tie down the shoots, so as to induce the lower eyes on the plants to break, this process usually resulting in more numerous flowers from the secondary growth than would otherwise be secured, though in some instances the individual flowers may be smaller than those of the first crop. This Rose, in common with a majority of the Hybrid Tea class, being subject to attacks of "black-spot," should be watered carefully, so as to keep the roots in as healthy a condition as possible. This fungus spreads much more rapidly on those plants which have defective root-action.

PERLE DES JARDINS.—In many cases the first crop of flowers

of this standard sort will have been cut by this time, and it will be necessary to thin out some of the weak and comparatively worthless growth around the bottom of the plants, so as to allow more air and light. At the same time it is advisable to give a little encouragement to the new growth by the application of fertilizers, preferably in a liquid form, although good results may also be obtained from a top dressing of manure. An objection has been urged against the latter method by some growers, however, on account of the greater difficulty of regulating the amount of moisture at the roots of the plants when the surface of the soil is covered with a coating of variable thickness and consistency. But whichever method is adopted in the culture of this variety, it would be well to keep in view the opinions expressed by several of our leading Rose growers, to the effect that the malformed buds frequently seen on *Perle des Jardins* during the winter months, are largely due to too liberal treatment or over-feeding.

PAPA GONTIER.—It seems evident that this Rose can be grown to better advantage in a house by itself, where this is practicable, for when grown among other varieties its peculiarities may be forgotten, and it may suffer from too great heat or too much water, when the growth is sure to become weak and the leaves fall off rapidly. *Papa Gontier* is naturally a strong grower and quickly responds to proper treatment, giving a plentiful crop of its handsome buds in rapid succession. During the past summer it has received much praise where it has been tested out-doors, making strong growth and producing large and highly colored flowers.

THE BRIDE has also made a place for itself in the foremost rank of Roses for winter use, and when afforded treatment similar to that recommended for its parent, *Catherine Mermet*, it usually produces a greater number of flowers of the same graceful form, and with the additional advantage of being white, and, therefore, of much greater general utility. In fact, this is now claimed to be the most

useful white Rose in general cultivation.

Philadelphia.

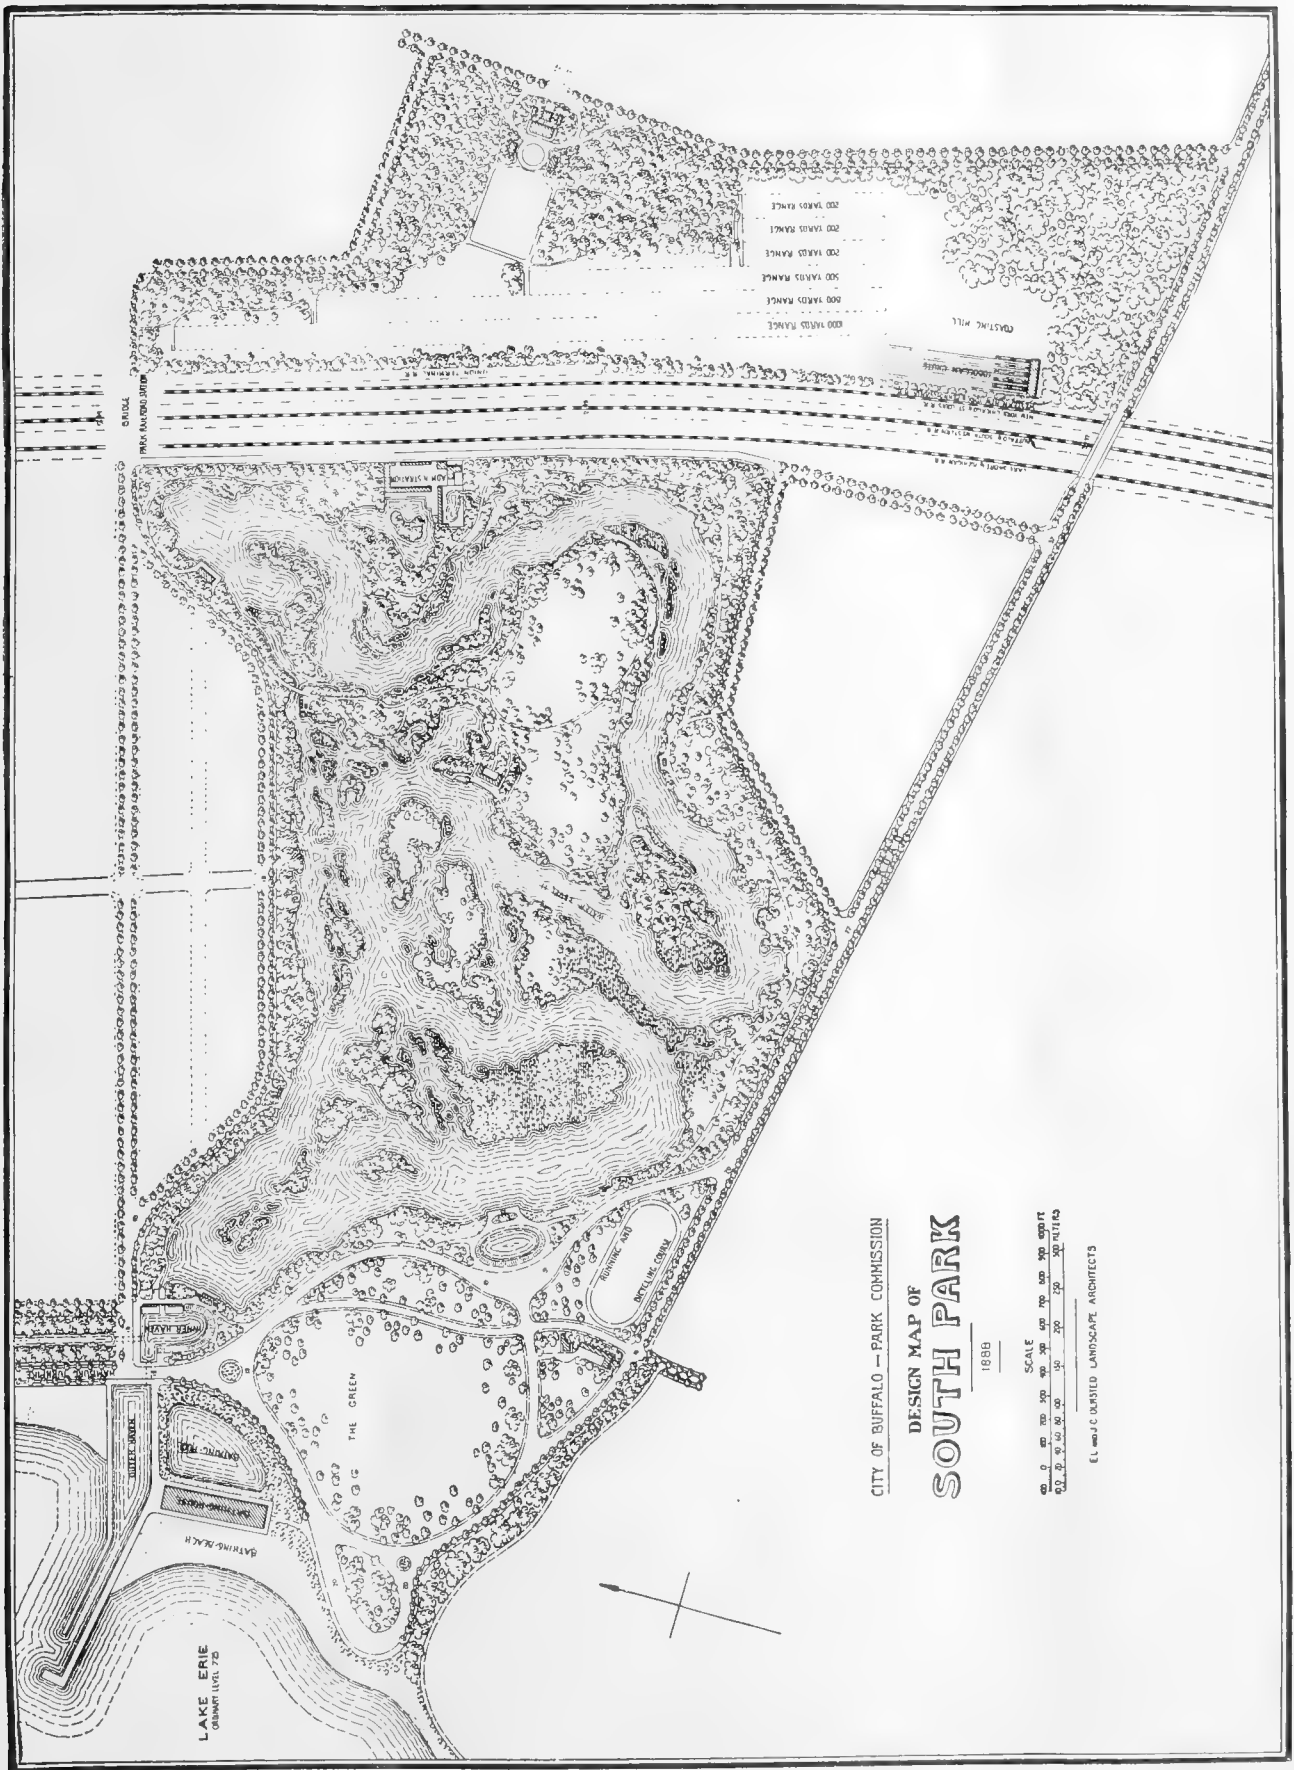

Hardy Perennials for Autumn.

THREE of the best hardy plants for autumn blooming are the common *Aster Nova Anglia*, *Anemone Japonica*—both pink and white varieties—and various species of *Kniphofia*, commonly known as *Tritomas*. I think it would be worth the trouble to prepare a bed for these specially to bloom together. The *Aster* is quite hardy, increases rapidly, either by seeds or division, and requires no further care. *Anemone Japonica* cannot be relied upon here to endure the winter, nor even farther southward, in New Jersey, though Mr. Vick, of Rochester, reports that it is quite hardy with him,

Fig. 72.—*Berberis Fendleri*.—See page 460.

W.

and it would be interesting to know whether protection beyond snow covering is given, and, if so, what kind. Neither can the Kniphofias be relied upon to endure the winter.

Mr. Harris, gardener to Mr. H. H. Hunnewell, tells me he used to keep them through, until the last few winters, when he has lost them, by tying their leaves up in the shape of a cone, and putting a few leaves around the plants. He also states that they were hardy many years ago in the Annapolis Valley, Nova Scotia. However, the safest way is to store both Anemones and Kniphofias.

The propagation of *Anemone Japonica* is quite easy. The strongest crowns or roots are planted for blooming the same season in the ordinary border, and the small roots are put into nursery beds, where they will grow large enough in one season to bloom the next year. Any piece of root will grow. Here in Massachusetts, with September frosts, it is necessary to start the plants in pots, either in moderate hot-bed or in a green-house, to hasten the blooming period. Anemones, planted three in a ten-inch pot, make fine specimens for hall decoration. It is safe to water them three times a day during the summer.

Kniphofias are raised from seeds or propagated by division. They thrive well in a deep, rich loam, and require plenty of water during dry weather. They require a fully exposed position or they will not bloom well. Kniphofias are generally called Tritomas in the trade, and most of those sold are *K. aloides* or its varieties. It is seldom, however, that the varietal rank is given to any of them—all being entered in the catalogues as species. This causes much confusion. Nicholson, in his "Dictionary of Gardening," has, no doubt, been as careful as possible not to give any varieties of *K. aloides* specific rank, but some of the species I believe are only varieties. But it is hard to pronounce positively, since the authorities are not given. *K. carnosae* and *K. Leichtlinii*, from trustworthy dealers, grown together, proved to be identical; so also did *K. Burchelli* and *K. Rooperi*.

Of the varieties of *K. aloides*, Media does not differ from the type. Grandis and Grandiflora, both noble plants, are identical; so also are Nobilis and Saundersii, though somewhat inferior. There is also a very handsome hybrid with the pretty little *K. Macowani*, known as *Tritoma media Macowani*. *K. caulescens* is so very distinct that it might pass for a *Dracæna* as regards habit of growth. It forms a decided stem, and does not bloom until four or five years old, and then from the axils of the leaves, not terminally. I consider *K. Macowani* and its variety *Corallina* the best for this district. They bloom early and continuously, produce seed in abundance, and are very easily raised by that means, blooming the second year. No other Kniphofia is so useful for cutting for house decoration, the varieties of *K. aloides* being altogether too coarse.

Wellesley, Mass.

T. D. Hatfield.

Orchid Notes.—*Odontoglossum grande*.—This species bears the largest and showiest flowers of the whole genus, and is a desirable plant for any collection, as it is easily grown and produces its flowers at a very welcome season. It was discovered about fifty years ago, growing in dark ravines in Guatemala, and therefore cannot be classed among the cool Orchids, but will be found to require the temperature of the Cattleya-house. For a potting compost we use a mixture of peat, fibrous loam, rotten leaves and moss in equal parts, taking care that the pots are thoroughly drained. While in active growth the plants require plenty of water; after this is finished they should be rested in a dry atmosphere, and given no more water than necessary to keep the bulbs plump. The racemes appear as soon as the growth is finished, bearing six or seven flowers, the lanceolate sepals of which are yellow barred with brown. The petals are brown on the lower half and bright yellow on the upper; the pale yellow lip is blotched with red. *Saccolabium bigibbum* is a pretty and somewhat rare species of close-growing habit, bearing linear-oblong leaves about seven inches long. From the axils of these are produced very short-stalked racemes with about a dozen pale yellow flowers. The lip is curiously saccate and triangular, white, with a yellow centre, while the edge is exquisitely frilled. It is a native of Rangoon, and grows well with the *Phalænopsis*.

Phalænopsis intermedia Portei.—This is a choice, and, at present, exceedingly rare Orchid. When first introduced it was thought to be a natural hybrid between *P. rosea* and *P. amabilis*; and to prove this Messrs. Veitch & Sons crossed these species and succeeded in raising a seedling which proved to be identical with those received from their native country. This same seedling is in bloom with us now, bearing a large, branching spike. In growth it much resembles *P. amabilis*,

while the inflorescence presents an intermediate character. The flowers are roundish and about two inches across; white suffused with rose near the base. The lip—the great attraction—is of a rich, dark purple. This hybrid is exceedingly free flowering, in fact it is difficult to keep a strong plant from being always in flower; but this should be prevented or the plant will soon become exhausted. It grows freely with the usual *Phalænopsis* treatment. The crossing of this hybrid with its parent, *P. amabilis*, has resulted in the production of that fine hybrid, *F. L. Ames*.

Vanda insignis is an old, but little known plant, and until recently it was very rare. For some unexplained reason, it has always been confounded with the slender-growing, narrow-leaved variety of *V. tricolor* called *insignis*, but now that the former plant is once more in cultivation, the difference in growth may easily be seen, especially in the leaves, which are much shorter and more rigid in the genuine species. The racemes bear some seven flowers about the size of those of *V. tricolor*, but they differ a good deal in shape. The sepals and petals are brown spotted with chocolate, while the lip is large and spreading, and of a uniform light rose. It is a native of the Island of Timor, where it grows on low trees much exposed to the sun, resting for a long time during the dry season. In cultivation it grows and flowers freely with the usual *Vanda* treatment. A beautiful and rare variety named *Schrœderi* has light yellow sepals and petals, and a pure white lip.

Kenwood, N. Y.

F. Goldring.

Notes From the Arnold Arboretum.

DECIDUOUS shrubs or trees which still possess beauty of foliage or of fruit after the 1st of November are not numerous in this climate and are therefore valuable. There are still a few in this collection; and these can be mentioned, perhaps, with advantage to persons contemplating the formation of new shrubberies. The Yellow-root of the Alleghany Mountains, *Zanthorhiza apiifolia*, a low shrub, specially valuable on account of its spreading habit for the margins of shrubberies and for clothing the ground among larger plants, is still covered with leaves, which are now bright orange colored. The small brown flowers of this plant, which appear in slender drooping racemes contemporaneously with the unfolding leaves, are neither showy nor ornamental. The real beauty of the Yellow-root is in the late autumn, when brightly colored foliage is not common.

Berberis emarginata, which has been mentioned more than once in these notes, is now at its best, and it is hard to imagine any shrub with more brilliant or strikingly colored foliage. *Berberis Chinensis* is very brilliant, too, but *B. Thunbergii* has already lost its leaves entirely. The fruit will remain, however, upon the branches bright and unshriveled until spring, and considerably later than those of the last named species, which on the whole, although still almost unknown in gardens, is a more graceful and desirable plant and unsurpassed among *Berberis* in the beauty of fruit.

Spiræa Cantonensis, which is often known as *S. Reevesiana* and of which there are a single and a double flowered variety in cultivation, is remarkable among *Spiræas* for the persistence of its leaves in autumn. They are still quite green and fresh, with only a slight change to yellow in the case of a few growing low down upon the stems. It is one of the most ornamental of the whole genus, although here unfortunately it is not quite hardy, losing the ends of the branches in severe winters.

Parrotia Persica, a native of the south and south-west coast of the Caspian Sea, and nearly allied to the Witch Hazel, is now a brilliant object, with its broad, golden colored leaves. This is a tall growing, robust and hardy shrub, which is not very often seen in American collections, although worth growing for the handsome coloring of its autumn foliage. Neither the flowers nor the fruit are at all showy. A second species, *P. Jacquemontiana*, a native of the Himalaya from the Indus to the Ravi, does not appear to be in cultivation. This plant is interesting from the fact that its tough and pliable twigs are used to make the swinging twig-bridges over the great Himalaya rivers. Among *Viburnums*, *V. cotinifolium* is now the only one which needs mention. It is a stout and spreading species, a native of the north-west Himalayas, where it grows between 4,000 and 11,000 feet elevation, and closely allied to the European *V. Lantana*. Its broad ovate or rotundate leaves are just turning to a deep, rich vinous red color. This plant has not flowered here yet, but the persistency of its foliage and the beauty of its autumnal coloring make it a desirable addition to the list of hardy shrubs.

Cornus sanguinea is the last of the Dogwoods to hold its leaves and its bright black fruit. This is the common Dog-

wood of Europe ; it is a hardy, fast-growing shrub, but of no great ornamental beauty. Loudon's suggestion that its specific name is due to the bright coloring of the foliage in autumn is not a very fortunate one, if we can judge by its behavior in this country, for no plant retains here green leaves more persistently.

The Washington Thorn, *Crataegus cordata*, is still a brilliant and beautiful object, with its small, bright red fruit and orange and scarlet leaves. This is one of the most rapid growing and desirable of all our Thorns as an ornamental tree, and it is free or nearly so from fungus attacks, which ruin the beauty early in the season of many Thorns. Formerly it was much more generally planted, especially as a hedge plant, for which purpose it is well suited, than at present. It is one of the most desirable of the smaller North American trees for ornamental planting. The foliage, however, of *C. arborescens*, is still more brilliant, surpassing here this year not only all other Thorns, but nearly every plant in the collection. *C. arborescens* is found in the south Atlantic States rather sparingly, and again west of the Mississippi River from Missouri to Texas. Like many of the other Thorns, it is most common and most fully developed in the valley of the Red River; here it is, when in bloom, a conspicuous feature of the region, bordering the low, wet prairies and the banks of streams, sometimes reaching a height of forty feet, with a round, wide spreading top. The bark of the trunk is much lighter colored than that of the other species, and the flowers, although small, are produced in the greatest profusion. The fruit is small, hardly larger than a pea, and bright red. It is rather a surprise that this plant should prove hardy here. So far, however, it grows vigorously and rapidly, and its further development will be watched with much interest. The astonishing and unsurpassed color of its foliage at this season of the year, should give this Thorn a place in every garden where it can be grown successfully.

Quercus Georgiana is one of the rarest plants found growing spontaneously within the limits of the United States. It is a low spreading bush, with leaves not unlike those of the Scarlet Oak, with smooth and shining saucer-shaped cups, and oval, globose acorns, and it is found nowhere else than upon the summit of Stone Mountain, in Georgia. This interesting shrub is perfectly hardy here, and just now its leaves are of the most intense scarlet color.

The genus *Smilax* is only represented in the collection yet by three species. Of these, *S. Pseudo-China* still retains its dark green leaves, which show no signs of turning to any other color before falling. The leaves of *S. rotundifolia*, the common Green- or Bull-brier, were brilliant scarlet and orange a few days ago, although now they have nearly all fallen, while those of *S. glauca* are just turning orange. These are all useful and handsome plants, and were they less common, they would be often seen in gardens, especially the Green-brier, which is one of the very best plants which can be used in this climate to make a shrubbery, or a boundary wall impenetrable and impassable.

Among North American trees, none, perhaps, retains its foliage green and fresh so late in the season as the Nettle tree, *Celtis occidentalis*. The leaves are all upon the branches still, and only here and there show a tinge of yellow. This is not a common tree east of the Hudson River, but further west and south, and especially in the far south-west, it is one of the largest, and most widely and commonly distributed of our native trees. It varies remarkably in habit and in the size and shape of the leaves, and botanists have at different times, for this reason, applied to it several different names, believing that there were several species, although it is probably wiser to consider all the different forms as included in one variable species. Sometimes it is a low bush only a few feet high ; sometimes, especially in the Mississippi Valley, it is a tall, wide-spreading tree, with rigid branches, and a tall, straight trunk ; in the valley of the Rio Grande it is low and wide-spreading, resembling an Apple-tree, with a short trunk and round head. Upon the banks of the Hudson River, opposite Newburgh, in New York, it grows with a slender trunk, and long, graceful and pendulous branches, which give to these trees, in this particular region, a character peculiarly their own.

It is certainly remarkable that this tree is so little known to horticulturists and so rarely planted. It is easily raised and grows rapidly. It is readily transplanted, and it is not at all fastidious about the soil in which it grows. It is an excellent tree to plant upon the lawn or along the road-side, and yet it is practically unknown in nurseries, and in the east certainly it is never planted—a fact which can be partially explained, perhaps, that it resembles somewhat, although a smaller tree, the Elm in habit and general appearance, and so has never become familiar to persons who are not botanists. J.

November 6th.

The Forest.

The Forest-tree Plantation of the University of Illinois.

THIS timber-tree plantation was begun in 1871 and covers about fifteen acres, with twenty-five species. The land was originally prairie, the usual deep, black, loamy soil, but varies considerably in richness and drainage. During thirty years previously the land had been used in ordinary farming, had never received manure of any kind, but was still good enough over the greater part of the area to produce average crops of Corn—say, fifty bushels to the acre. A part, however, was not so good. This last is upon the highest and naturally best drained portion, where, without manure, few field crops would satisfactorily grow. The lowest parts are too wet in spring-time for early tillage. Tile drains in this part would, it put down three feet, carry water at least half the season. None, however, have been laid. An open ditch across the plantation is the only artificial outlet for water. This does not usually dry up until after midsummer. The latitude of the place is a few miles north of the fortieth parallel.

The trees are in north and south rows—those first planted four feet apart; the later ones, eight feet apart. The earlier plantings were made two feet; the later, mostly four feet apart in the rows. Thinning has been practiced from time to time, by removing alternate rows among those at first four feet apart, and by cutting away from one-half to three-fourths of the trees from the rows. As the stand was originally good, the trees are now quite thick upon the ground.

The following table gives the kinds and quantities of trees and date of planting, together with the average measurements of the trees, on July 27th, 1888 :

	Acres.	Distance planted.	When planted.	Age in years.	Average height, feet.	Average diameter, inches.	Condition.
Ailanthus.....	1/2	4x8	1881	2	20.4	9.	X

In the column showing the present condition of the various kinds of trees one X denotes poor; two, fair, and three, excellent order. The last are thrifty, fine in shape, and in every way promising.

This comparison of the degree of successful growth among the different varieties is perhaps the most instructive thing in the plantation. It is easy to see that some kinds thrive when planted quite thickly in blocks by themselves, while other varieties, which may succeed in the open ground or in mixed plantations, fail if thus crowded by trees of their own kind.

Another table, giving costs and receipts, will be found interesting. It will be seen the latter are very small, mostly from sale of the young trees for transplanting. There should also have been a small credit for stakes and poles used on the farm, for which no account was kept. So far nothing can be said in favor of the undertaking for profit, whatever may be the ultimate outcome. Surely fuel cannot be profitably grown in this way when the best cord-wood sells for \$5.00, delivered, and good bituminous coal for \$3.50 per ton. Ordinarily, the thinning has been done for the product cut away.

	Cost of trees.	Cost of planting.	Cultivation, etc.	Total cost.	Receipts.
Ailanthus.....	\$10 40				
Apple.....	50 00	\$25 20	\$15 00	\$90 20

Among the trees which flourish when planted by themselves are the Conifers in general, the Sugar Maple and hardy Catalpa. The European Larch is planted in long rows, reaching from the driest to the wettest portions of the soil. On the first it has done magnificently well. The trees are now about eight feet apart each way, evenly distributed, uniform in size, beautiful in shape, and thrifty in growth. On this part of the ground they average ten to thirteen inches in diameter of trunk. On the lower and richer land they are practically a failure, not from the richness of the soil, but from the excess of water.

The White Pine is quite as promising, and thrives remarkably even upon the wet soil. The trunks are straight and tall, vieing in friendly rivalry to reach the sunlight above them, and beneath excluding it by the density of their shade.

The Norway Spruce also does well, and on the low as well as the higher ground, while the Scotch (Riga) Pine comes in as a fair second to these three of the first and finest growth. But the Scotch is not so agreeable in company. Those gaining the advantage crowd out the weaker plants to a greater extent; the limbs show the same tendency among themselves, and thus a few large side branches live longer, and ultimately form larger knots than are found on the trunks of the other kinds.

The Austrian Pine is the least successful among the Conifers, owing principally to a fungous disease affecting the foliage.

The hardy Catalpa stands at the head of the list of flat-leaved kinds for quickness of growth, erect, symmetrical shape and durability of wood. The other species, *Catalpa bignonioides*, is too often injured by the winter to be successful. The Hard or Sugar Maple grows slowly when young, but after the first ten years rapidly overtakes some of the more precocious kinds. Both the Maple and Catalpa thrive excellently in close association among themselves, their dense shade keeping the ground beneath free from undergrowth of all kinds. This is only partially true of the Black Walnut. While it is marked among the thrifty and promising kinds, the trees will evidently do better in mixed plantations, as usually found in nature. Its shade is not very dense, but its vigorous roots will not let many other trees have much chance near by. A proper selection and alternation is sure to be useful in this case.

A mistake was made in the Ash trees. White Ash (*Fraxinus Americana*) was to have been planted, but the nurseryman who sold the seedlings and the committee who bought them were alike unable to distinguish this species in the seed-bed from the Green Ash (*Fraxinus viridis*). The same thing often happens among those whose business it is to handle trees and nursery stock, but this no less makes the blunder a bad one, and one that surely ought to be avoided. But the Ash trees generally thrive greatly better in mixed plantations, and the

Green Ash conspicuously so. The average diameter of the trunks of those planted in a block by themselves, about eight by twelve feet apart, seventeen years old, is seven inches, while some of these same trees, taken as thinnings from the rows and planted elsewhere, are nearly double this size. In the block the trees are also very irregular in size. The smaller ones are not killed outright, but have little vitality and make slow progress. Among no other kind of tree is there so much undergrowth of vines, shrubs and weeds. They are evidently incapable of utilizing the sunshine in any such exclusive way as the Pines and Maples.

In the same way the Osage Orange is a failure. A specimen left here and there in a hedge does remarkably well for some years, and even thickly planted in a single row the trees are fairly successful; but they have badly disappointed many in their poor growth in the plantation. Planted originally two by four feet apart, they have from time to time been thinned to about eight by eight feet. Now, at the end of sixteen years, they averaged only five inches in diameter of base of stem. Neither are the trees in good shape for timber purposes, being crooked and scrawly in trunk and limbs.

The White Willows reach skyward above all the other trees and for summer fuel probably lead the list. It may be that for special manufacturing purposes this wood will be worth growing. The soft Maple (*Acer dasycarpum*) stands next the Willow in height, and makes clean, straight trunks with a dense canopy of foliage above.

University of Illinois.

T. J. Burrill.

Correspondence.

To the Editor of GARDEN AND FOREST:

I have an Osband's summer Pear-tree, one-third of which has been grafted into the excellent Reeder variety. In the summer of 1887 the tree began to blight somewhat, and has continued to do so through the summer of 1888. As yet the Reeder portion of the tree has not been affected (with the possible exception of one small twig). Fearing that I may lose the tree, and desiring to preserve the Reeder variety, I propose to graft it (the Reeder) into other trees. Will it do to take the scions from the healthful Reeder portion of the blighting tree?

Amherst College, Mass.

A. D. Morse.

The Pear blight is caused by *Micrococcus amylovorus*, Burrill, and can be transferred from diseased Pear-trees to healthy trees by natural contagion or by inoculation. If the Reeder portion of the tree of our correspondent has already one twig affected with *Micrococcus*, it would, of course, be unwise to take grafts from the immediately adjacent branches. It is probably safe, however, to attempt grafting with the more remote twigs of the Reeder portion of the tree. At any rate, if the object is to preserve the Reeder variety, it is certainly better to attempt to graft other trees with the apparently sound shoots of the Reeder portion, than to trust to the tree already grafted, a part of which, at least, is known to be diseased. It would, of course, be better still to procure grafts from other localities now free from the blight. It is to be hoped that our correspondent has before this cut off and destroyed the blighted branches on his tree.

W. G. F.

To the Editor of GARDEN AND FOREST:

Sir.—In the issue of your paper for October 3d, in the description of *Rhododendron Vaseyi* under "New or Little Known Plants," I noticed a mistake in regard to the locations in which it has been found growing. It was stated that it was "found in Cashier's Valley, South Carolina," etc., subsequent to its being discovered by Mr. Vasey, near Webster, in Jackson County, North Carolina. Cashier's Valley is in Jackson County, North Carolina; and from the best information I find that *R. Vaseyi* has not been detected outside of this state, and only in two counties—Jackson and Mitchell. It may be of interest to add that *R. Vaseyi* has been found growing quite to the top of Grandfather Mountain, at almost 6,000 feet elevation, and in this high location it seemed to be perfectly at home, being vigorous and flourishing.

Highlands, N. C.

H. P. Kelsey.

[By an oversight, the name of the town near which *R. Vaseyi* was found during the present season, appeared in our description as Louisville. It should have been Linville.—Ed.]

Periodical Literature.

IN a recent number of *Nature* are summarized a series of articles, written for *Les Missions Catholiques*, of Lyons, in which M. Armand David, a Lazarist missionary and distinguished man of science, recounts the scientific gains which have accrued to the world through the labors of Catholic ecclesiastics in the East. Few persons realize how great these gains are—how much self-sacrificing energy has been spent by missionary priests in studying the flora and fauna of the regions where their proselytizing work is carried on. In China especially their labors have been invaluable. To speak of botany alone, the first work of importance on the flora of China, published this year at the expense of the French government, in two finely illustrated quarto volumes, describes M. David's own collections, and is called "*Plantæ Davidiana*." Although it contains only a small proportion of the plants native to the empire, it deals pretty fully with those of the northern provinces and the Mongolian mountains, and adds largely to the list of the discoveries of English and Russian explorers. Many important European genera—like the Trefoils, for example—are not found in China, but many American plants have their representatives which are not represented in Europe—as *Pavia*, *Bignonia*, *Aralia* and *Dielytra*. A pretty plant (*Xanthoceras sorbifolia*), much cultivated in Peking, M. David found growing wild in Mongolia, and successfully introduced into France. Another find was *Davidia involu-crata*—a comparatively tall tree with large leaves, for the introduction of which, we are told, a considerable reward has been offered by an English amateur. M. Delavay is another missionary who, inspired by M. David, and, like him, helped with government money, is exploring with much success. His residence in the almost unknown province of Yun-nan gives him a good field for work, and the collections he has sent to France are the most important yet received, and will soon be published with M. Frauchet as editor. Where only one Chinese Primrose was formerly known, M. Delavay has raised the list to more than thirty. Instead of four or five Chinese Rhododendrons, forty-five have been made known through his labors and those of M. David. Several new species of Vine have also been discovered, among them one (*Spinovitis Davidiana*) found in a wild state in the central mountains of Tsin-lin, is noteworthy as having its stems covered with spines. Many other priests devote much of their time to forming collections for the French museums, and it would be difficult to overrate the sum total of their services, which, moreover, have been as great with regard to the fauna as with regard to the flora of the East.

Horticultural Exhibitions.

The Philadelphia Chrysanthemum Show.

THE Chrysanthemum Show of the Pennsylvania Horticultural Society, held in Philadelphia last week, was especially strong in the number and quality of the plants exhibited. The floor of the spacious hall was filled, and almost every plant was worthy of mention for its healthful appearance and its abundance of well-developed flowers. The general effect of this mass of color was admirable, and it was heightened by the garlands of Laurel, the Palm branches, the evergreen boughs, the bright-colored autumn leaves and berries, the bunting and Japanese lanterns, with which the walls and balconies, stairway and stage had been decorated by the Florists' Club of the city. There were fine examples of plants struck in summer and carrying a single bloom, but they were comparatively few. The cut flowers were of excellent quality, and while no single fifty equaled Judge Benedict's collection in New York, there were many more of them, all told, and the general average was better.

The finest plants in the hall were specimens of *Marvel*, *Grandiflorum*, *Lucrece* (new), Mrs. Frank Thompson, Mrs. C. H. Wheeler, Mrs. A. Blanc, *Cullingfordii*, M. Freeman, Robert Cranford, *Bride* (new), Mrs. William Bowen (new, brighter in color than Mrs. C. H. Wheeler, but resembling that fine variety), Mrs. William Singerly, Mrs. Joyce and *Puritan*. All these make the strong growth needed for exhibition specimens. Some of the varieties with most beautiful flowers, like Mrs. J. J. Bailey and Mrs. J. Wanamaker, do not grow large enough.

Among the noteworthy seedling plants exhibited was an unnamed variety grown by H. Surman, gardener to Mr. E. W. Clark. It is an improvement on his seedling, Mrs. E. H. Clark, which won the highest premium in 1887; a second was shown by William Jamison, and a third by Robert G. Carey,

gardener to Mr. J. C. Price, of Chestnut Hill. The finest seedling plant was a specimen of the Mrs. W. K. Harris, the flower of which has been mentioned.

The most notable cut blooms exhibited here for the first time, and remarkable for size, color and quality, were Mrs. Alpheus Hardy, which has already been described in these columns; Mrs. William K. Harris, shown by Mr. Harris—of great size and substance, and probably the finest yellow *Chrysanthemum* yet produced; L. Canning, pure white, Mrs. M. J. Thomas, blush white, and E. H. Fidler, bright bronze yellow, incurved and distinct in form—the last three shown by Craig & Brother; Lillian B. Bird, the largest flower with tubular florets, and Kioto, chrome yellow, shown by E. L. Fewkes, Newton Highlands, Massachusetts; Wootton, white, shown by John M. Hughes, gardener to Mr. George W. Childs; and Mrs. Carnegie, John Thorpe's wonderful variety, for which a gold medal was awarded. The silver medal went to Robert Craig, for Mrs. Isaac C. Price, a beautiful yellow of large size and distinct form.

The premiums were very liberal. A prize of \$100 was awarded to J. W. Colflesh for the twelve best plants. A second prize of \$85 went to John Kinnear, gardener to Mr. J. J. Bailey; a third of \$65 to Gordon Small, gardener to Mr. William H. Singerly, and a fourth of \$50 to Mr. W. K. Harris. There were many other special money prizes, gold and silver medals and silver cups. The principal awards, besides those already named, were made to William Tricker, gardener to Judge Benedict, of Staten Island, William Dewar, P. Conlan and Gebhard Huster, gardener to Mrs. Heyl.

The attendance was unusually large, and altogether the exhibition can safely be described as the most successful of its kind in the history of this venerable society.

Chrysanthemums at Boston.

AT the exhibition of the Massachusetts Horticultural Society, which opened in Boston on Wednesday of last week, prizes were offered for Chrysanthemums alone, and yet both halls of the Society were well filled with plants and cut flowers. On the stage at the farther end of the large upper hall was displayed a collection of sixty plants from Edwin Fewkes, arranged in a sloping bank, the colors being admirably blended and contrasted. Along the entire length of the front of the stage was a bright terrace of cut flowers. In the centre of the hall were the various plants in competition for the prizes for specimens, while around the sides were the large groups in the twenty-plant class. Altogether, the scene presented to one looking down from the gallery was really brilliant. As a rule, the plants were not remarkable. They were fairly good, however, and were commendably free from artificial training and unnecessary staking and tying. One of the most remarkable plants in this hall was a seedling of an unusually deep orange color shown by Dr. Walcott, who also contributed flowers from other seedlings of conspicuous merit. Several of these were from seeds of Mrs. Wheeler, and one, a sport from *Nil Desperandum*, was a large, full, creamy white.

The cut specimen flowers surpassed, in size, variety and beauty, the best shown at any former exhibition. Two lots of twelve, contributed by Miss Simpkins, of Yarmouth, were superior in uniformity of excellence to anything in their class, and won both the first and second prizes.

Very striking were some of the novelties shown by Fewkes & Son, of Newton Highlands, especially those from the Japanese collection sent originally to Mrs. Alpheus Hardy, and including the famous variety named for her.

These flowers have attracted much attention in other exhibitions this year, and some of them rival the Mrs. Hardy in beauty, although not in novelty of form. A seedling from Mrs. Wheeler was shown by Mr. E. A. Wood, which is even richer in color than that admirable flower, and which has the additional advantage of being very double to the centre. Of the cut flowers in vases, mention should be made of some blooms of *Cullingfordii* and *Jardin des Plantes*. They were grown by Mr. C. J. Power, of South Framingham, and as displayed on long, strong stems, they showed a grace of form and richness of color which nothing short of the most intelligent cultivation could produce.

The principal prizes, except those already mentioned, were awarded to E. W. Wood, Mrs. F. B. Hayes, Joseph H. White, Mrs. E. M. Gill and P. Malloy.

A superb specimen of *Cypripedium insigne* was exhibited by W. H. Martin, gardener to Mr. N. T. Kidder, of Milton. The plant bore ninety flowers, and perhaps no finer one was ever grown.

Notes.

Hill & Company, of Richmond, Indiana, received the leading prize at the Chrysanthemum exhibition at Indianapolis.

Messrs. Pitcher & Manda, of Short Hills, New Jersey, have lately secured a white flowered variety of *Masdevallia Harryana*—the only plant of the kind known to exist.

The banquet at the opening of the Chrysanthemum exhibition in Philadelphia last week was pronounced a most enjoyable and successful one by the many visitors who were present at the hospitable invitation of the Florists' Club, of that city.

The Proceedings of the Annual Convention of American Cemetery Superintendents, held at Brooklyn in September last, have been published in a neat pamphlet. The papers read and the discussions which followed contain much interesting information and sound doctrine.

German horticultural papers note with surprise the number of the florists who attended the recent convention in New York, and with still more surprise the distances over which many of them traveled to be present, "some of them actually coming three thousand miles"! According to their witness it was the largest meeting of horticulturists that has ever been held in the world.

The trustees of the Massachusetts Society for Promoting Agriculture voted, at a recent meeting, upon the request of Mr. B. E. Fernow, to contribute \$100 towards the cost of the exhibit to illustrate the forests and forest products of the United States at the Paris Exhibition of 1889, which the officers of the Forest Division of the Department of Agriculture are preparing.

We are apt to think that the cultivation and naming of numerous varieties of fruits is a comparatively modern practice. But how far from true is this belief may be shown by the fact that between the years 1598 and 1628 Le Lectier, Royal Procurator at Orleans and a famous pomologist, collected in his garden 262 varieties of Pears. In 1628 he printed a long catalogue of fruits, and caused it to be circulated with the request that cultivators would inform him with regard to all varieties as yet unknown to him.

According to the *Illustrierte Garten Zeitung*, of Vienna, no less than a hundred varieties of the Beech are known in gardens. The most recently introduced variety, called *Fagus sylvatica conglomerata Bandrilleri*, has twisted, almost rolled-up leaves, and a very short, dense spray. A favorite tree for street and formal planting in Germany is the so-called "Bullet Acacia," which has a tall, straight stem, surmounted by a dense spherical head; and the new Beech is recommended as a good substitute for this Acacia, as it can be grown to a similar shape without the use of shears, its leaves appear earlier in the season, and it often retains them throughout the winter.

Chrysanthemums of great beauty are sold this year in the streets of Boston in surprising numbers. A bunch of flowers, such as hardly existed in the United States five years ago, can be bought now for fifteen or twenty cents from the itinerant flower-sellers seen in all the most frequented parts of the city. The improvement of the Chrysanthemum and its growth in popularity is one of the most remarkable and encouraging signs of horticultural development in the United States. It is a question whether this flower does not have a stronger hold upon popular favor in this country than even the Rose. But if this is true, it is only temporary. The Rose has held its own for centuries. New favorites come and go, but in the long run the Queen of Flowers maintains her supremacy in all lands and among all people, and she will continue to do so.

Of Winter Apples for market in New England, the Baldwin, Rhode Island Greening and Hubbardston continue to hold supremacy, and last winter the Rhode Island Greening, for some unknown cause, kept better than the Baldwin. Professor Maynard reports, in a late bulletin of the Massachusetts College Station, that the Pewaukee, a seedling of the Oldenburg, possesses all the vigor and productiveness of its parent. The fruit is of good size, striped and splashed with red and covered with a deep bloom. It is a late keeper, of fair quality and has borne heavily every year in the college orchard. Sutton Beauty, owing to its fine flavor, its beauty and its productiveness, is slowly finding its way into orchards. Its medium size injures it in competition with so popular a variety as the Baldwin. The Red Russet, too, is gaining favor for the vigor and productiveness of the tree and the beauty and long-keeping quality of the fruit. The tree is as sturdy as the Baldwin and the fruit keeps as long as the Roxbury Russet.

Some exhibitors of Chrysanthemums endeavor to keep the blooms fresh for six or eight days, but to have them in the best condition on a given date they should not be cut earlier than four days before that date. Mr. E. Molyneux states in *The Garden*, London, that varieties of the darkest shades of color—chestnut, bronze, deep lilac and rose—lose their freshness more quickly than the lighter colored varieties, while primrose, yellow and white keep fresh the longest. The beginning of decay can best be ascertained by feeling the lower florets. These should be crisp and solid, not soft and flabby. The blossoms should be cut when fully developed and with a stem at least twelve inches long, so that a small portion of it can be cut off every day. Place the stem in a bottle of water to which salt has been added in the proportion of a teaspoonful of salt to a quart of water. The flowers should be placed in a cool, slightly darkened room having a dry atmosphere.

The Pomological Institute of Reutlingen, Germany, consists of two branches, a preparatory and a high school. The programme of studies to be pursued in the high school during the coming winter half-year has just been issued, and is of interest as showing how systematically and thoroughly horticulturists are trained in the Fatherland. Botany, with the morphology and anatomy of plants; pomology, drawing—each of these is to be studied during four hours each week. Two hours each are to be devoted to vegetable gardening, the theory of horticulture, geognosy and geology, chemistry, the care of woodlands, arithmetic, and the conduct of business. One hour a week is given to the means of preserving fruit from insect depredations, and the remaining time will be filled by practical work, experimental demonstrations and practice with the microscope. As aids to oral instruction the institute is supplied with model gardens, nurseries, orchards and plantations of small fruits, an arboretum, a forcing-house for fruit, green-houses of other sorts, a rich natural history collection, a large library, and maps, pictures, apparatus and models of every kind.

In spite of the fact that unexpected early frosts somewhat injured the Cranberry crop of southern Massachusetts, it is expected to reach greater proportions than ever before. The largest annual shipments are made from the town of Wareham, at the head of Buzzard's Bay, where nearly 18,000 barrels were packed last year. One bog in this vicinity covers 500 acres. Prices vary much, according to the season, but it is estimated that in a good year a cultivator who understands growing, harvesting and packing his berries may count half his receipts as clear profit. Wisconsin and New Jersey also grow Cranberries in large quantities, the former state sometimes producing double the yield of Massachusetts. But owing to the difficulty of protecting the western bogs against frost their yield is very uncertain, having varied during the past few years from as few as 13,000 to as many as 132,000 barrels. In Massachusetts, where innumerable brooks and rivers traverse the Cranberry districts, the bogs are surrounded by a system of ditches and dams so that they can be quickly flooded to a depth of several inches, and the berries thus protected against frost. The quality of the so-called Cape Cod Cranberry is also considered better than that of the western fruit, and has been largely exported even further west than Chicago. The harvest is usually completed about Thanksgiving time.

A horticultural firm in Holland recently received from its agents in Java a specimen of the gigantic Orchid, *Grammatophyllum speciosum*, Bl. Accompanying it was a description of a plant growing in the botanical garden at Buitenzorg, in Java, which we quote from the pages of the *Gartenflora*. "This plant now displays twenty-eight flower-spikes, which average eight feet in length, and some of which bear as many as seventy blossoms, about fifty blooming at once. The flowers measure six inches across, and each petal is three inches in length by one and one-half in breadth. The color of the sepals and petals is yellow with brown spots, while the comparatively small lip is purple streaked with brown. The stout flower-stalks stand mostly erect, as do the heavy pseudo-bulbs, some of which are as much as ten feet in length. As is the case with most Orchids, the flowers remain a long time fresh. The plant is a native of the forests of western Java and of some of the other islands of the Indian Ocean, although it is nowhere very common." *Grammatophyllum speciosum* was introduced into Europe by the Loddiges, and flowered in their nurseries during the year 1852. There is a figure of the rather imperfect flowers of this specimen in Paxton's *Flower Garden*, t. 69, and there is a much better figure in the *Botanical Magazine*, t. 5157, from a plant which flowered in England in 1859.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, NOVEMBER 28, 1888.

Injuries to Shade Trees.

THAT a well-formed, vigorous tree is worthy of respect and consideration, is a fact of which it is to be hoped no reader of GARDEN AND FOREST is either ignorant or unmindful. There is one point, however, to which public attention should be called, viz., to the danger arising from the removal of large branches of sound trees, either intentionally, by wholesale pruning, or by the violence of winds and storms, without proper subsequent care. If a branch is in the way, few persons now hesitate about cutting it off, no matter how large it is, and it is not a rare thing in our thickly-settled towns and their suburbs to see trees which have been reduced to two-thirds, or occasionally to one-half, their normal dimensions, by indiscriminate trimming. Or it may be that a superannuated family mansion has been sold for a few hundred dollars and removed to the outskirts of the town, to be transformed into a tenement-house which is to be made to pay several hundred per cent. to the shrewd purchaser. That is, perhaps, none of our business. But it does concern us if the house has to be dragged through a mile or two of streets, crashing and tearing off the branches of shade-trees on the way. Recently a three-hundred-dollar house did much more than three hundred dollars' damage to trees during its slow passage down the streets of a city, which need not be named.

In the first place, by such acts of violence, or even vandalism, the beauty of the trees is diminished, and they become not only unsightly, but also less valuable as shade trees. That is evident to every one. But the more serious evil of which I would speak is one which is not recognized at the time. The trees are not killed at once, to be sure, but the open wounds made by breaking or cutting off good-sized branches are just the places in which the spores of many destructive fungi lodge and grow. So long as the bark remains as a covering of the wood, such spores do not readily find an entrance to the wood itself. Of course, there are some fungi which destroy trees by entering the leaves or roots. But the fungi now referred to are rather certain toadstools, punk-fungi and their allies, which, while they do not grow upon the leaves and

not usually on healthy roots, often attack open wounds where the wood, exposed to the action of the weather, becomes naturally somewhat rotten. Once established in such places, the mycelium of these fungi makes its way slowly but surely into the adjoining healthy wood, until, in comparatively few years, the whole tree becomes diseased. The mycelium is not annual but perennial, and bears, on the surface, repeated crops of toadstools or punk, as the case may be. Knowing this fact, one should hesitate before cutting off large branches, and so endangering the life of the tree itself. We know the dangers from open wounds in animals, and we must also recognize that they are dangerous in plants. If one wishes to be convinced of the truth of these statements, he has only to walk along the streets of any town in late summer, and notice how frequently toadstools and punk are growing on the scars where branches have been removed. If the wounds are of some years' standing, and have not been treated, as all wounds upon trees should be treated as soon as made, with a coating of coal-tar or paint, he will probably also find rotten spots on the trunks themselves, in which fungi are growing, which have developed from the mycelium that has penetrated into the trunks from the old scars.

In this connection one should notice the wounds caused by the bites of horses fastened to trees. In thickly settled regions this evil is a serious one, and householders should be compelled by law to place some protection around the parts of the trunks of trees on their sidewalks likely to be injured by horses. Oxford Street, in Cambridge, Massachusetts, affords a good illustration of the evil. For some distance the trees have been bitten by horses, and on the side of the trunks facing the street there are large wounds, which are not only unsightly, but which have also caused a disturbance of nutrition to such an extent that the trees are sickly, and, in some cases, apparently dying. The health of trees which are for the benefit of coming generations as well as our own should not be endangered by the carelessness of those who now live near them.

Uses are constantly found now for minor products of our forests which, until recently, were considered valueless. A conspicuous example of this fact is pine-fibre matting, which is manufactured, in North Carolina, from the leaves of the Long-leaved Pine (*Pinus palustris*). The industry is a new one, comparatively, but it has already become important, and it is likely to grow as the value of the matting made from Pine leaves is better known. A bagging material is also made in the same way, which can be used for covering cotton-bales. This fact is now creating much interest in the cotton-producing States, because the price of jute-bagging, which up to the present time has been the only material used for covering cotton-bales, has been enormously increased by the manipulation of a combination of importers who control the supply, and who have formed a jute-bagging trust. It is now believed that Pine-leaf bagging will prove the best substitute for jute. Should this expectation be confirmed, the production of this article may be expected to be very large in the course of the next few years.

The green Pine leaves, collected in the forest for the purpose, are purchased at the factories for fifteen cents the 100 pounds. They are first cleaned, and then placed in large iron cylinders set on end and surrounded with steam-pipes. They are then thoroughly steamed, the vapor being conveyed through pipes into an ordinary distillery-worm in an adjoining building. Pine-leaf oil, a valuable antiseptic, is obtained in this way at the rate of about one-half gallon for 100 pounds of leaves. The leaves are then boiled to remove the silica, which is found in their outer covering, and which can be used in tanning leather. The leaves are next boiled again and bleached, and are then ready to be dried, which is done in machines, by means of which all moisture is evaporated from them. The fibre is then ready for manufacture, and is put up in burlap bales weighing twenty-five pounds. The Pine-leaf

fibre has also been found valuable by surgeons in the treatment of fractures and in dressing wounds. It is an excellent disinfectant, and probably many other uses will be found for this long-neglected product of the forest.

From a note in the *English Mechanic and World of Science* it appears that the paper manufactured from the wood of the Red Cedar (*Juniperus Virginiana*) has been found useful for underlaying carpets and for wrapping wool, furs and other articles liable to be injured by moths, which are driven away by the peculiar odor of this wood. The wood from which this paper has been made has been the waste of pencil factories; but if it is found to possess the value which is attributed to it, the establishment of pulp mills in parts of this country where the Red Cedar abounds will, no doubt, prove an exceedingly profitable enterprise. The Red Cedar is the most widely distributed of North American trees. It is found growing, often in great abundance, from Canada to Texas, and from the shores of the Atlantic to those of the Pacific. In some parts of the country, especially in Florida, where the best pencil wood has been procured, and along the valley of the Red River in Texas, it grows to a large size, with tall, straight trunks, which yield straight-grained lumber of high quality. More often the trunks of the trees are short, often contorted and filled with knots, and, therefore, unfit to manufacture into lumber, and up to this time have been of very little value, except for fence-posts and inferior railway-ties. If Cedar paper, however, is really valuable, the trees which have been considered worthless can be profitably utilized. In the central and in the eastern parts of the States of Kentucky and Tennessee there are hundreds of square miles of rocky and sterile soil—Barrens, as these lands are known locally—covered almost entirely with Red Cedars, which, if they can be profitably manufactured into paper-pulp for this special purpose, will give a much greater value to these lands than they have ever been suspected of possessing.

Newport.—I.

I THINK the first thing that strikes a foreign visitor to Newport must be the singular way in which evidence of lavish expenditure mingles with signs of an almost pauper disregard for appearances. Such contrasts often reveal themselves in America, but seldom so forcibly as here. The town to which the great colony of costly and ambitious summer villas is attached, is much less neatly kept than is the rule in New England, and certain of its outlying streets—constantly traversed by pleasure-seekers in gorgeous equipages—are a veritable offense to the eye. At one step we pass from little palaces, surrounded by exquisitely kept grounds, almost into "Shantytown" itself. Nor are striking signs of carelessness absent, even though we keep strictly within the villa districts. Even on Bellevue Avenue the borders of the road are left untended to a degree which, in Lenox, for example, would not be tolerated for a week; and where a vacant lot occurs, its fence is a tumble-down, weed-grown affair, that a respectable farmer in a rough country village might blush to own. I have heard it said that Newport, despite its claims to art and taste, to elegance and fashion, is, as a whole, a vulgar-looking place. The term is too harsh, yet there is some excuse for its application. In many places we seem to read a regard for what is visibly one's own combined with a disregard for what is everybody's; a love of display united to a lack of public spirit, which should certainly not characterize a refined community.

The best part of Newport is the beautiful Cliff Walk, which runs for more than three miles on the edge of the lifted rocky shore, passing villa after villa set back beyond verdant lawns. An old public right of way has most fortunately kept this walk open and free, although the land all belongs to the villa-owners; and the appearance of brotherly concord between neighbor and neighbor and generosity towards the public, which it seems to reveal, added to its intrinsic charms, has made it a frequent theme for praise with foreign writers on landscape gardening and the arrangement of country towns. Here, at least, no signs of carelessness appear. The soil along the cliffs is, by nature, thin and poor, so it requires an immense amount of care and money to make and keep these lawns, although the damp climate favors the work. Well kept and

fresh they are, indeed. "And no wonder," I heard a lady exclaim, "for when there are signs of a drought, the owners come forth and water them with their tears." The statement that the particularly beautiful turf which covers the two or three acres of a certain gentleman is annually taken up and rolled away in his cellars over winter, is an equally amusing fiction; yet this I heard told more than once, with an accent which almost implied belief in its truth.

Beautiful and appropriate as are these lawns on the landward side of the Cliff Walk, a mistake has perhaps been made in continuing them on its seaward side, where they skirt with a very narrow border the rough rocky edge of the cliff, or are carried down the slope for a considerable distance in places where the rocks lie lower. In such places as these they have too much the look of earth-works for defense; and everywhere they unite but poorly with their bold rocky finish. The pathway might better, perhaps, have been taken as the boundary line for the lawns, and the spaces beyond, whether wider or narrower, treated in a naturalistic way—made to look as though the hand of man had not tampered with their original covering.

The fierce sweep of the sea winds in winter is, of course, injurious to the growth of trees in such exposed situations as those along the Cliff Walk; but shrubs and flowers can be made to grow with great luxuriance. The lapse of five or six years has surrounded many of the newer houses with rich thickets of tall shrubs and even with trees of considerable size; and year by year veritable carpets, in the shape of formal beds of bright flowers and foliage-plants, are spread out around them. These beds deserve admiration from the merely cultural point of view—nothing could be better, as far as luxuriance and neatness are concerned. Nevertheless, I think they may be counted as another item to excuse the cynic who speaks of bad taste in connection with Newport. Bold effectiveness, rather than beauty, seems, as a rule, to have been sought for alike in their composition and in their disposition. As a rule, their colors are crude and inharmonious, and they are multiplied out of all reason and placed where they do the greatest possible harm to the effect of the grounds as a whole. The fact is doubly to be regretted, for Newport is the very place where formal bedding might often be used to the best advantage. Nowhere do we see so many houses of the most formal and dignified character standing close to a road or even a street, and surrounded by very small grounds. In such cases a formal disposition of the grounds might well suggest itself as the most appropriate. But to be good in effect the scheme should be consistent. Formality should reign and rule, not merely occur in certain features. But, instead of straight-lined roads and paths and regular arrangements of shrubberies, clipped hedges and formally shaped trees, with which pattern-beds and borders would be in true accord, informal schemes are seen where landscape effects are simulated in miniature—where winding drives and paths are flanked by "natural" groups of trees and shrubs and tall flowering plants—sadly interfered with, often, indeed, wholly ruined, by a profusion of flat beds and borders, rigid in outline and gaudy in color. No outlines can be too formal for such beds, if they are graceful in their own way and if the general scheme sanctions formality; and no colors too bright, if harmony in contrast has guided their selection. But I think we may look in vain at Newport for a place in which all these conditions are respected.

There are exceptions, however, to the general and excessive use of bright set beds and borders. Here and there—as in the pretty grounds of Mr. Sheldon, on Narragansett Avenue—a small expanse of lawn is made the most of by plantations which merely fringe its borders, and lies in refreshing peacefulness, undisturbed by notes of gaudy color. Mr. Goelet's large place, again, where this avenue meets the Cliff Walk, needs the removal of but one or two beds to make it perfect. There is no other house in Newport at once so beautiful and so appropriate in its beauty, and none so charmingly connected with its grounds. When I saw it the wide lawns were in perfect condition, rising into a low, grassy terrace all around its base; vines had grown upon it to just the right extent; a few formal plants in pots appropriately adorned its steps, and the masses of green which decorated the piazza towards the sea were undisturbed by over-prominent notes of color—a single yellow flower-pot giving just the one needed touch of brightness.

This, I think, is a type of what a Newport house should be when its grounds are comparatively large, and when a further air of spaciousness and country freedom is given them by an open seaward prospect. But it would be less appropriate on a more contracted site with no frontage save towards a street.

Here villa-architecture, properly so-called, is more appropriate—houses which shall be neither city residences of the usual pattern nor true country houses, but midway between the two. No one can find fault if a Newport house, no matter how small its grounds may be, is itself large and costly. It must be this, in very many cases, or it will not fulfill its purpose. But it is a mistake to imitate in its fashioning either an English type of country house, which needs a stately park about it, or the boldly picturesque shape of some American country home which commands a wide prospect over picturesque acres of its own. Dignity is required, and, to a large extent, symmetry also; an air of sumptuousness and generous accommodation combined with a certain reserve as of a building near its neighbors and near the public gaze. The "colonial" style, which of late has been so extensively revived in many parts of the country, seems to offer, perhaps, the best type for such a house. And it seems as though here of all places we might expect to find it used, as the old town of Newport was one of the chief centres of colonial art. Nevertheless, new "colonial" houses are conspicuous by their absence. The only one I noticed is apt to be overlooked by the transient visitor, lying, as it does, in one of the older streets, half hidden by trees. This is the beautiful brick house built not long ago by Messrs. McKim, Mead and White for Colonel Edgar. It is as entirely appropriate to its place as is Mr. Goelet's house, and the difference between them is all the more instructive since the same hands designed the two.

The back of Mr. Fiske's house on Ochre Point is charming in both form and color—a happy relief in its lowness and its quiet browns from the towering outlines and strong tones which too often meet the eye. But its best feature is the wall of beautiful pinkish stone which connects it with the stable and the street. It was a wholly fortunate idea to edge the base of this wall with a narrow border of bright-hued plants, as they enliven the prospect but do not disturb it, being thus closely connected with architectural forms. And this summer the vines had grown upon the wall, as upon the house itself, to exactly the right extent—softening and adorning but not wholly concealing the surface. The great trouble in some places is to make vines grow; the great trouble at Newport is to keep them within bounds. The recent introduction of the so-called Japanese Ivy has already meant in many places the entire concealment of the forms beneath it. When these are bad the result is a happy one—a seeming wall of verdure is certainly to be preferred to an ugly fence or foundation story. But when the forms and colors are good, then their concealment detracts from beauty, while the vines themselves look best with a visible background. On Mr. Fiske's house, and on Mr. Goelet's as well, it will be a pity if the vines are ever allowed to exceed their present estate. On many other houses one might wish them to grow to the very chimney tops.

M. G. Van Rensselaer.

New York.

The Japanese Plums—The Satsuma.

SINCE I wrote of the Kelsey Japan Plum, Batankio (or Batankin, as some call it), last month, I was so fortunate as to find young trees of that most curious of fruits, the Satsuma Plum of Japan, or, as it is now quite generally known, the Japan Blood Plum, in fruit in the grounds of the University of California at Berkeley. The tree is a much stronger, smoother grower than the Kelsey; leaves smoother and more lanceolate, wide in the middle and narrowing to each end; twigs stout, long and smooth. The fruit is round, with a deep suture on one side; dark dull red, with bloom, flesh dark, bright crimson or cherry red; skin very thin, with no acidity; flesh or pulp very fine grained, very juicy, abundant free blood red juice; when fully ripe, melting and delicious. We may say, first best in quality to eat from hand when fully ripe. The Plum, when first mature, is quite firm, and will prove a good long shipper. When over-ripe, it becomes very soft, but still juicy, and not mushy. In size, the Plums examined were about the size of the native Plum known as Miner, or about the size of the well-known Green Gage, but it is said to grow much larger. The stem is longer and more slender than that of the Kelsey, which is very short and thick for a Plum. The pit of the Satsuma is quite small for the size of the fruit, roundish, somewhat pitted and corrugated.

This Satsuma very closely resembles in tree, leaf and growth a Plum tree sent east from California under the name Ogon, which proved quite hardy with me in Illinois in our severest winters, much more so than the Kelsey, and it may be that some of these fine fruits may do well in the great north-west. Since I wrote of the Kelsey last month I had some of them stewed for sauce, and found them very nice served in that way.

Many young orchards in different parts of this state of the Kelsey have fruited for the first time in quantity this year, and all report them very productive and profitable. The keeping qualities of these Plums are truly remarkable. I have before me a very large specimen of the Kelsey, gathered when fully mature, one month ago yesterday. It is yet perfectly sound.

That the Kelsey is quite near to the Peach in many of its peculiarities is plain to any one who will examine it critically. It has the stem and pit of the Peach. The pit is corrugated, pitted and shaped like that of the Peach, and the kernel has the same skin and flavor, and fully bears out the view that I had long ago formed from observation, namely: That we may expect, and that we now have, hybrids between nearly all the different species of the Almond family, and that we may look for very valuable future results from such hybrids.

Hybridism brought about by skillful artificial means should be continually striven for, though we may have 10,000 failures for each success. Given our fully hardy native Plums as a base—they lacking somewhat in self-pollenization, making them easy to experiment with in this line—should give the north-west in time some good, fine hardy fruits.

The high mountain regions of northern California have some fine native Plums that may prove of value in this work. But it is best for those who work for the great north-west to stick pretty close to the wild Plums of the northern part of that region. Some of them are really fine, valuable fruits in their wild state and capable of endless improvement.

The Plums proper, those of the European type, are not proving as profitable in California as the other members of the Almond family. They nearly all do finely and bear enormous crops of magnificent fruit, but are too acid when canned or dried, except the Prune section. Of these the sweet, raisin-like French Prune, the Petit Prune de Agen, is grown in great quantities, and is still being more largely planted than any other fruit. The tree is a strong, healthy, handsome grower, wonderfully productive; the fruit very sweet and easily dried into the Prune of commerce. The crop is very regular and certain. An item before me gives the yield of an orchard in Tulare County, only four years old, at 300 to 500 pounds to the tree. At the lowest price Prunes have sold at on the tree this season, a cent and a quarter a pound, and at the lowest figure of product as given, to wit, 300 pounds, we would have a net return from this orchard of \$375 an acre, and this in Tulare County, which, twelve years ago, was considered a worthless arid desert.

But give the exceeding rich soils of these so-called deserts a little good water from the mountains and we have at once the fruit growers' and fruit tree and vine paradise, where nearly all the fruit-bearing trees and plants will grow and thrive wonderfully, and where great commercial fruits, such as the Raisin Grape, Prune, Peach, Nectarine, Apricot, Fig and Pear, can be perfectly dried in the open air cheaper and better than anywhere else in the world where they can be grown with success. And this is not all. In the hot, dry, even morning air of the great Joaquin Valley, but very few of the insect enemies, so injurious to fruits, can propagate, and none—yes, we may say *none*—of the destructive moulds, blights and rusts, so destructive in moist climates, can there exist. Sun-dried fruit there is as perfect, from these reasons, as the very best evaporated fruit east.

Over 500,000 acres have just been redeemed from the sway of the Jack rabbit in Merced County, by the great Crocker and Heffman canal, costing a million and a half of dollars. This adds that amount of the very best of soils in one of the best fruit regions in the state, in a fine, healthy climate.

D. B. Wier, in *American Florist*.

"Gardening, in the perfection to which it has been lately brought in England, is entitled to a place of considerable rank among the liberal arts,—it is an exertion of fancy, a subject for taste; and being released now from the restraints of regularity and enlarged beyond the limits of domestic convenience, the most beautiful, the most simple, the most noble scenes of nature are all within its province; for it is no longer confined to the spots from which it borrows its name, but regulates also the disposition and embellishments of a park, a farm, or a riding; and the business of a gardener is to select and to apply whatever is great, elegant or characteristic in any of them,—to discover and to show all the advantages of the place upon which he is employed; to supply its defects, to correct its faults and to improve its beauties. For all these operations the objects of nature are still his only materials."—From Thomas Whately's "Observations on Modern Gardening," London, 1770.

New or Little Known Plants.

Pentstemon rotundifolius.*

TO the red-flowered Pentstemons, which are among the most ornamental species of this showy genus, Mr. Pringle last year made an interesting addition, of which Mr. Faxon has now given us an excellent figure. As found growing from the crevices of cliffs in the mountains about Chihuahua, with its large panicles of scarlet flowers drooping over the rocks, its habit seems very unique. In the character of the flowers it appears to be most nearly related to *P. centranthifolius* of Southern California and Arizona, having the same narrow, tubular corolla, with a nearly equally lobed, erect limb, though in this respect it is also much like *P. Eatoni*. The plant is very glabrous and glaucous throughout, woody at base, and the stem quite leafy. The thick leathery leaves are rounded and entire, and, except the lowermost, are closely sessile. *Pentstemon rotundifolius* flowered during the present season in the Royal Gardens, Kew, from seed collected by Mr. Pringle.

S. W.

Foreign Correspondence.

London Letter.

THE season has come when not a single important class of plants is in full bloom. I went through some of the great nurseries this week, and was surprised to find them so flowerless. Chrysanthemums, which from November through the winter occupy the attention of all gardeners, have, it is true, a few very fine forerunners, which tend to enliven our green-houses, and it is satisfactory to see that every season brings new early varieties of this flower. Frenchmen seem to be very active just now in raising new October-blooming sorts of the Japanese and other large flowered sections, and at the meeting of the Royal Horticultural Society on Tuesday last there was quite an array of new varieties, of which four only were considered worthy of first-class certificates. Having regard to the enormous number of varieties now in cultivation, and the obvious difficulty in comparing the new with the old, the committee are wise in not awarding certificates precipitately. Of the four certificated, the finest by far was one called Sunflower belonging to the Japanese section. It has large flowers and very long florets, which hang gracefully like a tassel. The color is the brightest yellow imaginable. It was shown by W. Holmes, the Secretary of the National Chrysanthemum Society, who considers it not only the finest early yellow, but one of the best of all yellow Chrysanthemums of its class. Another first-rate novelty is Lincoln's Inn. It is a large flower with shortish florets, which are a rich, brown crimson on the upper side, and yellowish below. Edwin Molyneux, also certificated, is a large and not very beautiful flower, being coarse in the opinion of many. It is like that named Comte de Germiny, but is of a brighter chestnut-crimson. The fourth sort was Magicienne, with large flowers and reflexed florets of a reddish orange hue. Besides these a fifth sort named Capucine was selected on account of its floriferousness. The flowers are small, the color bronzy orange, and the habit of growth good. It is called a "decorative variety." Among the other new sorts shown I singled out the following (all Japanese sorts) as the best: C. J. Quentus, pink; Charlotte de Montcalrier, long florets, pink; Madame C. Souchet, chestnut-crimson, reflexed; Othello, yellow and crimson; C. Wagstaffe, good, large, pure white; T. Stevens, pale pink; Mad. Louise Leroy, white and pink; and C. Delmas, crimson. Some of these were scarcely forward enough to allow us to judge adequately of their merits, and consequently were passed over by the committee.

A few Orchids of exceptional interest were shown, and three of them were certificated. The most remarkable was the *Cattleya Lamberhurst Hybrid*, a cross between *C*

citrina, which always grows downwards, and has large, wax-like flowers of deep yellow, and *C. intermedia*, a well-known old species. The hybrid has its growth with a decided downward tendency, the flowers are not so large as those of *C. citrina*, the sepals and petals are blush-pink, while the labellum is prettily marked with rose-pink and white. Though not a gorgeous Orchid, it is extremely pretty, and possesses a great interest for growers. Another new hybrid, also raised by the late Dr. Harris, of Lamberhurst, was *Cattleya Harrisii*, a cross between *C. Mendelii* and *C. superba*. In this case, too, the characters of the parents are strikingly blended in the cross. The flowers are about as large as those of *C. superba*, and resemble those of that species in form. The sepals are rose-colored, the broader petals deep rose, while the lip is a beautiful crimson-carmine. These two hybrids came from Baron Schroeder's rich collection at Egham, and are extremely rare. Another certificated Orchid was a new *Oncidium*, shown under the name of *O. Mantieri*. It is a supposed natural hybrid between *O. Forbesi* and *O. Marshallianum*. It much resembles the first named in growth and in flowers, though there are evident traces in its features of the showy yellow of *O. Marshallianum*. It will, no doubt, prove a valuable plant if it habitually flowers in October, when Orchid-houses require enlivening.

One of these Orchids came from Messrs. Veitch, who also won a certificate for their new Javanese Rhododendron named Yellow Perfection, which is far the finest pure yellow sort yet raised. The truss is enormous, and the flowers are two inches across, with broad, overlapping petals which are of the clearest chrome-yellow. Messrs. Veitch themselves think that this is one of the greatest strides they have made in this race of green-house Rhododendrons. These shrubs are now a most important class of green-house plants, and, since their culture is becoming better understood, they are becoming popular in all good gardens. In an intermediate house, not an ordinary green-house, they require the simplest treatment, and they may be called perpetual bloomers, as they seldom are out of flower. At Veitch's nursery one can see, at the present time, a large house full of flowering specimens, representing a large number of sorts, every one beautiful. In color some of the older kinds have not been excelled by the newer hybrids. None are now more pleasing in color than the old Taylori, one of the earliest hybrids, and Princess Royal, also one of the first. But the improvement has been in size of truss and bloom, as well as in the shape of the flower. I look upon these Rhododendron hybrids as one of the best among the many great things accomplished by the Veitches during the present generation, and their name will always live in connection with these beautiful plants. The great desideratum now is a new Rhododendron of a distinct color which would hybridize with the present race.

London, October 25th, 1888.

The Flower Garden.

AS our garden is on the north shore of Long Island, it is not visited by frosts so early as are those of our more inland neighbors, and this year has been exceptionally mild. Until to-day, Nov. 15th, but two slight frosts have occurred. The garden, therefore, is still gay with the blossoms of many plants.

Chrysanthemums are now in their glory, and make a magnificent display where massed in banks against the south side of buildings, and even in open garden beds where they have been grown all summer. Wind and rain batters them about and injures the flowers if left unsupported, but where well tied up to a stake, the flowers are held steady and kept clean, and are in fine condition. Under out-door cultivation the colors are deeper than when the flowers are produced under glass, and in the case of some white-flowered varieties like Domination they display quite a lilac or purple tint. With Elaine, Fair Maid of Guernsey and some other whites, however, this rule does not hold good. Among our finest out-door varieties this year are Gloriosum, Gloria Mundi and Golden Dragon, yellow; Elaine, Jessica, Falconer's Early, Domination

**P. ROTUNDFOLIUS*, Gray, *Proc. Amer. Acad.*, xxii, 307. *Gardeners' Chronicle*, 3 ser., iv, 264, f. 31.

Fig. 73.—*Pentstemon rotundifolius*.—See page 472.

and Mrs. N. Hallock, white; Julie Lagravere, Cullingfordii and J. Delaux, crimson; Lakme and R. Walcott, red; Brazen Shield, Source d'Or, Early Red Dragon, and Incomparable, golden bronze; and Roseum Superbum, Mrs. Talford, Admiration and M. Panchenan, shades of purple. For an abundance of blossoms the named varieties are far inferior to our this-year's seedlings. Some of these are poor enough and some are good, but the unusual vigor of the plants and the immense masses of flowers they are bearing more than compensate for their ordinary quality.

A few years ago a large-flowered form of *Chrysanthemum segetum*, the European Corn Marigold, was introduced by seedsmen as a novelty. Although it is a very bright and pretty flower, it is a bad weed, and self-sown seedlings come up all about the garden where the old plants grew. Just now it is one of the brightest flowers in our garden, and the frost has not hurt it a particle.

The Meteor variety of the Pot Marigold is finer now than it has been before this year. It is from midsummer sowings. This flower, Mignonette, Sweet Alyssum, Pansies and Czar Violets, keep on blooming throughout the month of November, or even longer if they are not subjected to more than seven to ten degrees of frost. Zinnias and Heliotropes have been destroyed by frost, and African Marigolds, of which the Eldorado strain is a good type, have been considerably injured. The dwarf striped French Marigolds, however, keep on blooming as if it were yet only September, instead of November. Frost injures the flowers, but the unopened buds escape, and soon bloom out and renew the display.

Among Gallardias all the annuals are so far past as to be not worth keeping longer, but the handsome large-flowered varieties of *G. aristata* are still in excellent bloom. Two Centaureidiums, *C. Drummondii* and *C. Texanum*, both yellow-flowering composites, have been in bloom since midsummer, and are now in finer flower than they have been at any former period. *Coreopsis coronata* and *C. tinctoria* still supply a fair display of blossoms, but all of the other annual and perennial species are done blooming. *Rudbeckia bicolor* from June sowings is very showy and full. *Erigeron speciosum* is yielding a fair second crop of flowers; so, too, are the Red Valerian, Double White Feverfew and Indian Pinks. Summer sown Snapdragons have a few good flowers, and *Tagetes lucida* is finer now than it has been all summer.

The dwarf blue Alkanet is very fine; so, too, is *Cosmos bipinnatus*. For October flowers this *Cosmos* is one of the finest things ever introduced to cultivation. It blooms abundantly; its flowers are large, showy white or rose-purple, and last well when cut. The greatest fault of this noble Mexican annual is its habit of blooming so late in the season and its tenderness, for a degree of frost will ruin it.

One of the brightest and prettiest red flowering plants now in bloom in our garden is *Alonsoa Warscewiczii*. It can be treated as an annual raised from seed sown in spring and planted out over summer. It is now blooming more copiously than it has been at any other time of the year. Slight frost does not hurt it. Drummond Phlox is still abundant, but the plants are mildewed, and therefore the flowers are curtailed in proportion.

Christmas Roses (*Helleborus niger*) seem to be a little early this year; bunches of white flower-buds have risen some eight or nine inches above ground, but none of them are quite open yet.

Most of the summer tender vines have been killed down and cleared away. But *Manettia bicolor* is still studded all over with yellow-tipped scarlet flowers, and purple blossoms hang thickly upon the *Maurandia Barclayana* growing on a fence. *Cobaea scandens* raised from seed sown last March has run more than twenty feet over and along a high trellis fence, and is still full of its purple bell-shaped flowers and drooping seed-pods. A stretch of Lobb's Nasturtium (*Tropaeolum Lobbianum*) along a fruit-tree border in front of a south-facing wall had the leaves scorched a little by frost, but all the flowers that were protected by the peach shoots and Nasturtium foliage are bright and perfect.

Sphaeralcea Emoryi is a little plant which is still in good bloom, as it has been for a long time. It is a hardy perennial from the eastern slope of the Sierra Nevada, and has small terra-cotta red flowers in copious quantity. Perennial Larkspurs, Tritomas and Salvias still yield some flowers.

Glen Cove, L. I., Nov. 17th.

Wm. Falconer.

New Hardy Hybrid French Gladioli.

HAVING again, during the summer and autumn now drawing to a close, grown, for study and comparison with older varieties, the set of ten new hybrids of the *Purpureo-auratus* crossed with *Gandavensis* race, distributed towards the close of last year by M. Victor Lemoine, of Nancy, some notes as to their respective merits and beauties may perhaps induce others to cultivate these beautiful and easily-grown, hardy, bulbous plants. The comparatively cold and almost sunless summer we have had this year has in no way interfered with, but has indeed been far more suited to the growth and perfect blooming of these plants than the torrid season and long drought to which they had to submit last year, which prevented many of the varieties of that year from coming to perfection at all. The ten varieties belonging to 1888 are:

BOUSSINGAULT.—This commenced to bloom on August 1st, and is a very strong grower, producing three flowering bulbs from one. It has medium-sized, creamy yellow flowers, with most distinct and beautiful, clearly-marked lower petals, the outer half of which is deep canary yellow, the inner half deeply feathered maroon. This beautiful variety, also Louis Van Houtte and Oriflamme, were well figured on the colored plate appearing in the *Paris Revue Horticole* for May 16th, 1888.

DE HUMBOLDT is a vigorous-habited variety with good-sized flowers opening well together on the spike, and thus showing a good many flowers in full beauty at the same time. The color is a deep rosy salmon, with clear yellow under-petals, distinctly blotched with light maroon.

EMILE GALLE is rather a slender-growing variety which, in the bud state, promised to be of quite a novel shade of violet not hitherto met with in these hybrids, but on the expansion of the flowers they proved to be washy and pale in color, thin in texture and deficient in form. Only the lower petals are beautiful, being of a deep shade of violet with a thin line of gold down their centre. It is quite possible, however, that this, being quite a new break in color, may prove the parent of many beautiful varieties in years to come.

EUGENE LEQUIN is a variety of medium height, with pale lemon-colored flowers distinctly marked on the lower petals with broad blotches of velvety carmine, and is altogether an extremely pretty flower.

E. V. HALLOCK is a vigorous growing variety, and one of the most beautiful of the whole series, with large fully opened flowers of a clear, pale shade of canary yellow, the three lower petals clearly and evenly blotched with pale carmine. This should be in every collection.

LE HORLA.—A rather weak-growing variety, with flowers under the medium size, of a pale shade of red. The three lower petals are yellow, distinctly blotched with carmine, and the centre one edged with pale red. The flowers of this variety may come larger on a stronger plant.

MIRABEAU.—A rather weak grower, with large, well-expanded flowers of a somewhat dull shade of yellow, faintly flamed with carmine, and with broad and most distinctly marked blotches of deep maroon on the lower petals.

LOUIS VAN HOUTTE.—This is a rather dwarf-growing variety, with medium-sized, well-expanded flowers of a pale yellow shade of color, faintly blotched with carmine on the lower petals. The flowers open well together on spike.

ORIFLAMME.—A vigorous, tall-growing variety, with branching flower-spike, and producing deep rose-colored flowers, blotched with carmine on the lower petals.

VICTOR MASSÉ.—This is a washy, indistinctly colored and worthless variety, which did not, I think, deserve a name.

The seven varieties distributed at the end of 1886, and which I was unable to describe adequately last year, were:

MONS. A. THIERS.—This is a very pretty variety, of rather vigorous habit, with medium-sized, well-opened flowers, which are rather far apart on the spike, of a clear shade of deep rose, flaked with carmine. The lower petals are clear canary yellow, edged with rose and blotched with maroon.

MARQUIS DE SAPORTA is a variety with medium-sized scarlet flowers, with a lighter throat, and are closely set on the spike and open well together. The lower petals are rather indistinctly flaked with maroon-yellow.

MONTESQUIEU is a tall and vigorous grower, with large, well-expanded, light red flowers, flaked with carmine. The lower petals each bear a distinct and pretty flame of deep rose color tipped with yellow.

DE CHERVILLE.—This is a vigorous grower of medium height of spike, with flowers rather under medium size, of a rather dull shade of deep rose color, somewhat indistinctly flaked with maroon and yellow.

BRACONNOT.—A variety of medium height and not very

vigorous habit of growth, with medium-sized blooms of a deep shade of scarlet, prettily flaked with canary-yellow on the lower petals.

GOUNOD.—A rather weak-growing variety, with flowers of a rather dull shade of yellow, faintly shaded with rose color. The two lower petals are evenly divided between deep velvety maroon and clear canary-yellow, the latter outside.

JEAN JACQUES ROUSSEAU.—A variety with pale orange-scarlet flowers distinctly blotched with carmine on the lower petals; each blotch is edged with pale yellow. This is an exceedingly pretty variety.

M. Lemoine again sends out this winter fifteen more varieties of this race of hybrids. He has not, however, yet been able to get up sufficient stock of the beautiful new race of hybrids he has obtained by crossing *G. Saundersi superbus* with some of his own *Purpureo-auratus* race; of these he hopes to be able to distribute one or two varieties towards the end of next year. Another foreign nurseryman, M. Otto Frœbel, of Zurich, has also obtained some bright and pretty hybrids between *G. Saundersi superbus* and *G. Gandavensis* which he hopes to distribute shortly.

W. E. Gumbleton, in *The Garden*, London.

Ferns for the Window Garden.

ONE of the most common causes of failure in window gardening is unsuitable selection of plants. In fact, this is the principal cause, for, where man can live, some species of plants will thrive. After the Chrysanthemum is out of bloom, scarlet Pelargoniums, or some other flowering plants with bright colors, are generally selected for the window-garden. These cannot succeed where we cannot or will not allow clear, full sunshine. The living-room rarely affords this sunshine, which is necessary to the production of vivid color.

Most plants that have reveled in full light and pure air during the summer soon lose the bloom of health when brought into the living or sleeping room; they lose their strong, fleshy leaves, they become emaciated, and sicken and die.

For rooms where there is but little light, where the sun makes only a formal call once a day, Ferns will thrive luxuriantly, and the more beautiful species appear to thrive the best. As a family the Adiantums surpass all the others in graceful beauty, and of the species few can compare with the noble *A. Farleyense* or the delicate *A. gracilis*. These two I have grown with perfect success in the room of an invalid, when at times there would be but little light and hardly any full sunshine during the entire winter. So well did they succeed, that in spring they would have been given a prominent position at a Fern exhibition. In the same situation no flowering plants could be induced to grow; in fact, none were wanted, for none are as cheerful or restful to the weary eye as the delicate Adiantums. Some of the Adiantums make charming basket-plants; conspicuous among them is *A. Edgeworthi*, whose delicate fronds, when young, wear a lovely pinkish hue, gradually shading into a pale grayish-green.

If a climbing plant is wanted for the house, the Fern family will furnish this, too, in the *Lygodium scandens*, and a more beautiful plant, or one more easy of management, cannot be found. While it is a favorite in the green-house, and most useful for decorative purposes, it is well adapted to house-culture, as it requires but little light, and is not injured by gas or furnace heat, so fatal to most plants. It is a rapid grower, and with proper management can be made to complete its growth in summer, after which it can be introduced into any moderately cool room in the house, where it will remain an object of beauty the entire winter. There are scores of Ferns besides those named that are adapted for the house during winter; in fact, most Ferns do well, but none, I think, are as beautiful as the ones noticed. In using Ferns for the window one caution must be observed. Well-established plants must be secured to begin with. In their young and growing state they require a more humid atmosphere than the house affords, a condition that is not essential when the plant is fully developed.

Garden City, N. Y.

C. L. Allen.

Cosmos hybridus.—This valuable plant was introduced some years since into this place and is now a conspicuous ornament of many humble cottage gardens. It is, perhaps, a hybrid of *C. tenuissimus*, but, more probably, only a garden variety. This plant grows here to a height of six or seven feet, but I have seen specimens at least eight feet high. The finely cut leaves are very attractive. The flowers—pure white or pale rose colored and single—are about two and one-half inches in

diameter, with crimped and fimbriated petals, and are produced in great abundance in terminal bunches. They have a pleasant, faint odor, but can hardly be called fragrant. The plant is easily grown from seed, which may be planted in the open ground in May, though it would certainly be much better to plant early in April in a hot-bed. Judging from the plants which I have myself raised, as well as from all those which I have seen, it would be very advantageous to pinch in the shoots at an early period of growth, so as to make them more bushy and to cancel the tendency toward a somewhat loose and sprawling habit. Here, in Newport, *Cosmos hybridus* begins to bloom early in October. My own plants, which were raised from seed grown in the open ground about May 20th, are now, November 9th, in full bloom, and yield a daily supply of charming flowers, worthily succeeding *Anemone Japonica alba* and *rosea*, which the large blossoms somewhat resemble. Though a Mexican plant, *Cosmos hybridus* resists the early autumn frosts remarkably well. Dahlias were cut down by frost in my garden ten days since. In the absence of any information as to the parentage of this plant, I suggest that, possibly, some fine dark colors could be obtained by hybridization with *C. bipinnatus*. The great value of the plant as a late autumn bloomer will soon lead to its general culture.

W. G.

Newport, Rhode Island.

Pantratum speciosum belongs to a genus which is not grown so extensively as it deserves. The plants are mostly of easy culture, and with little trouble will produce abundant flowers. *P. speciosum* is one of the best of the genus, producing, in early winter, large umbels of pure white and very fragrant flowers, which last a long time in perfection. Even when out of bloom the plant is quite handsome, each bulb having four to six large, ovate, deep green leaves. The new leaves appear with the flower-spikes, and until they are thoroughly matured the plants require very liberal treatment—strong heat and abundance of water—and if the pots are well filled with roots, liquid manure should be given regularly. During the summer months the plants may be set out-of-doors in a shady spot and kept as dry as practicable without causing loss of leaves, which I think are better retained as long as possible. For potting material a mixture of sandy loam with a little leaf-mould will be found good. Pot firmly, and use large pots, so that repotting will not be necessary for some years.

Cymbidium Hookerianum is now bearing three racemes of flowers. In habit it much resembles *C. giganteum*, though much smaller; the leaves are a dark green, with streaks of yellow near the base. The semi-pendent racemes spring from the base of the matured bulbs, bearing about a dozen large flowers of a yellowish green, with the straw-colored lip blotched and spotted with crimson. The front lobe is very crisp. This species was introduced in 1866 from the Sikkin Himalaya, and should be grown in the cool house, with liberal waterings during active growth, and should at no time be kept dry. We use a compost—loam, peat and sand in equal parts. The plant grows very freely, but seldom blooms, and the flowers here are probably the first that have been seen in America.

F. Goldring.

Kenwood, N. Y.

Orchids in New York.

THE fine collection of Mr. Hicks Arnold on Eighty-fourth Street, in this city, occupies a lofty, span-roofed structure, which formerly was filled with Palms, Ferns, etc. The temperature of the house is kept as near as possible from 60° to 65° by day, and 10° lower at night. The plants have made good growth during the past summer, and promise abundant flowers. Orchids in bloom are rarely seen in quantity at this season, but at a recent visit I observed several worthy of note in flower, and among them a beautiful form of *Cattleya Dowiana*, with rich, well-developed blossoms, the sepals and petals being of a charming buff-yellow, the broad, dark purple lip handsomely veined with the brightest golden-yellow. A specimen *C. Gigas*, suspended from the roof, had produced five flowers of great size and of good substance, and the plant still has six newly-made flower-sheaths, which in a few weeks will make a grand display. Other *Cattleyas* soon to flower were fine plants of *C. Skinneri alba*, *C. Trianae alba*, the deep purple-flowered *C. Lawrenceana*, a strong-growing plant of the pretty yellow *C. luteola*, and a number of *C. Trianae* and *C. Mendelii*. Well-grown plants of *Laelia Perrinii*, in position near the glass, had a number of sheaths, and several were already in bloom. *Laelia purpurata* and *L. elegans* were represented by strong specimens, and a plant of the showy *Laelia Patinii*, which had made very stout growths, was well furnished with flowering

sheaths. In habit this *Laelia* resembles *Cattleya Skinneri*, and is a species of easy culture. Quite a fine selection of *Cypripediums* were growing very rapidly on the north side of the house, and among many others was the beautiful *C. Morgania*, a plant of *C. grande*, with foliage of a remarkably robust character; *C. ananthum superbum*, the new Hybrid *C. Godseffianum*, said to be a cross between *C. hirsutissimum* and *C. Boxalli*; *C. Io* in bud; *C. alium*; strong plants of *C. Curtisii*; *C. Leeanum superbum*, showing flower; *C. Shlemii album*, *C. Veitchii*, *C. praestans*, *C. Lawrenceanum biflorum* in bloom, and a fine example of *C. albopurpureum*. A number of *Dendrobiums* were looking at home at the warmest end of the house. Specimens of *D. Wardianum* were just completing their new season's growth, having bulbs measuring some four feet in length. A plant of *D. nobile Sanderianum*, said to be the finest of all this section, was doing well in a teak basket, having made a very stout lead, and with it were plants of *D. Ainsworthii* and *D. Leechianum*, both scarce and very showy. Flower spikes were showing in quantity on well-grown plants of *Phalænopsis*, including *P. Sanderiana*, *P. Schilleriana* and *P. amabilis*, and the lovely *P. tetraspis*, with its blossoms of the purest white. A beautifully-grown specimen of *Angracum Scottianum* had just passed flowering, having produced as many as thirty snow-white blossoms. A large plant of *Angracum eburneum* was specially noticeable, with twelve strong spikes from four sturdy growths, and during the months of January and February will make an effective show. *Vandas* and *Arides* were hanging in numbers from the roof, and were pushing their roots to the outer surface of the baskets, enjoying the moist and warm atmosphere so beneficial to them. A fine example of *Vanda cerulea* had produced a stout spike, and will bloom very shortly. Several well-grown plants of *Arides Lawrenceana*, *A. Sanderianum*, *A. Houletianum* and others were exceptionally fine, with foliage of a very deep green. The *Odontoglossums* that were enjoying this temperature were *O. Roezlii*, *O. vexillarium*, and a plant of the chaste and pretty *O. Warsceviczii*, which was rooting freely in a glazed pan, and suspended near the glass in close proximity was a large plant of *O. Phalænopsis* in bloom, its white and violet-crimson markings strikingly effective. A lean-to structure of small dimensions contained a group of the cooler species, including some strong plants of the *Odontoglossum crispum* type, *O. Pescatorei*, *O. crestatellum*, several already being in bud.

During the past summer a number of plants were subjected to out-door treatment with very satisfactory results. A light, open, frame-work structure, some twenty-five feet long by ten wide, was erected on the lawn, with a stage for the plants three to four feet from the ground, the only covering being a sheet of the thinnest canvas to protect them from the direct rays of the sun. Above this was fixed another roll of very stout cloth, nearly water-proof, which was immediately let down when cold winds or storms were expected. In this way the following plants, amongst many others, have made rapid and unusually fair growth, viz.: *Odontoglossum Alexandrae*, *O. Pescatorei*, *O. citrosimum*, *O. grande*, *O. Rossii*, *O. Harryanum*; all the varieties of *Laelia anceps*, *Oncidium ornithorhynchum*, *O. tigrinum*, *O. incurvum*, *O. varicosum*, *O. Marshallianum*, *O. sphacelatum*, *O. Cavendishianum*, *Laelia autumnalis*, *L. albida* and *L. majalis*, *Ada aurantiaca*, *Cypripedium insigne* and its varieties, *Calogyne cristata*, *Lycaste Skinnerii*, *L. aromatica* and *Masdevallias* in variety. The plan is very cheap and simple, and is well worthy of a trial, as it will be the means of preserving many of our cool-growing species during the extreme summer heat, which is so detrimental to the growth of the plants.

A. D.

The Lawn.—Should time and weather permit, lawns should now be raked clean with wooden rakes, so as to remove stones, dead grass, and leaves. This lessens the work in Spring. And in spots where the grass has been choked out by Sorrel, Mouse-ear Chickweed, common Chickweed, Creeping Speedwell, or Moss, rake off as much of the weeds as possible with a steel bow-rake, then mulch over the places with a heavy dressing of manure or compost. Rotted cow manure is the best for this purpose, as it is full of seeds of pasture grasses, and these come up so thickly in Spring that it matters little whether the bare spaces are resown or not. If lawns are to be top-dressed with manure, this is the proper time to do it, for in frosty weather carts can be driven over them without leaving wheel-prints in the soil. The dressing should by all means be scattered as it is hauled out on the grass, otherwise a stiff frost may come and prevent its being spread at all this season. Let the manure used for dressing be old and rotted fine.

G. C.

The Live Oak.

THE Live Oak (*Quercus virens*) is a familiar object to all persons acquainted with the vegetation of our south Atlantic and Gulf States. It is a large tree, although rarely growing to a greater height than fifty feet, with a short, thick trunk, sometimes seven or eight feet in diameter, and spreading, curved and often twisted branches. The trunk, which is covered with a deeply furrowed and very dark bark, often divides near the ground into several large branches, as in the characteristic specimen which appears in our illustration below, and which is growing near New Orleans. Sometimes the trunk does not divide until it has reached a height of twelve or fifteen feet, when it sends out immense horizontal branches which have

ascends to an elevation of nearly 8,000 feet. It is found on the coast of Guatemala and in Costa Rica. The Live Oak attains a great size and is very common upon the Sea Islands of the Carolinas and Georgia and upon the adjacent mainland. It is common, also, upon the Gulf coast east of the Mississippi. The distribution of this tree is interesting and not easily explained. Abundant on the humid coast of the south Atlantic States, which must be taken as the region of its greatest multiplication and development, it is able to endure the extremely arid climate of western Texas, where few broad-leaved trees can maintain a foothold. There are but two trees, moreover, so far as is now known, belonging to the real North American flora, which extend into the tropical climate of Central America—the Live Oak and *Pinus Cubensis*. The latter,

Fig. 74.—The Live Oak (*Quercus virens*).

been known to shade a space more than a hundred feet in diameter. The leaves are from two to three inches long, oval-lanceolate, obtuse, with entire and strongly revolute margins, or sometimes, upon vigorous young shoots, sharply toothed. They are coriaceous, dark green and lustrous on the upper, pale and pubescent on the lower surface, and remain upon the branches for twelve months, falling as the leaves of the succeeding year unfold. The cup is top-shaped, hoary, long-stemmed, and encloses the base only of the oblong, dark chestnut colored or nearly black acorn, which rarely exceeds an inch in length.

The Live Oak is found growing in the neighborhood of the coast from southern Virginia to Mexico; in Texas, west of the Trinity River, it extends into the interior, often as a low shrub, as far as the high mountain ranges in the western part of the state and into northern Mexico, where it

although it is not found quite so far north as the Live Oak, is confined to the seaboard from Carolina to the Mississippi, and then reappears upon the coast and on the uplands of Honduras and on the Guatemala coast.

The value of the wood of the Live Oak in ship-building was recognized soon after the settlement of the Southern States, and after the acquirement of Florida by the government of the United States, it created a number of reservations upon the west coast of the peninsula for the purpose of maintaining a supply of this wood for naval construction. It is very heavy, hard, tough and strong, of a light brown or yellow color, and susceptible of a beautiful polish. The large branches, often growing nearly at right angles with the trunk, made the strongest and best ribs for large ships which could be found; and at one time there seemed a probability that all the large specimens of this

tree would be destroyed for this purpose. The substitution of iron for wood in ship-building has saved, however, the Live Oak. The trees are too hard and too difficult to cut down to make them very available for fuel; and the wood, although unsurpassed in beauty by that of any other American Oak, is not much used in cabinet work, for which it is well suited, owing to the difficulty of working it.

"The Acorns," old Mark Catesby tells us, writing more than a century and a half ago, "are the sweetest of all others; of which the Indians usually lay up store to thicken their venison-soup, and prepare them other ways. They likewise draw an Oil, very pleasant and wholesome, little inferior to that of Almonds."

The Live Oak is perhaps the most ornamental of all North American trees in cultivation. It grows very rapidly when young, more rapidly, indeed, than most Oaks; it thrives in nearly all soils, even when its roots are washed by sea-water during periods of high tides; but to develop all its beauties it should be planted in deep alluvial soil or upon the Carolina phosphates. A few old avenues of noble Live Oaks, and some single specimens in different parts of the South, especially in the coast region of South Carolina, are certainly the most stately and majestic trees which men have planted in North America.

C. S. S.

The Forest.

Swiss Forest Laws.

THE Report of Mr. Conway Thornton to the British Foreign Office, on the Swiss Forest Laws, is a careful and interesting piece of work. From a summary which appears in a late number of *Nature* it is evident that from a very early date the various cantons endeavored to preserve the forests. Thus, in 1314, the authorities of one forbade "the felling, floating or selling" of timber from the Sihlwald; in 1339, another forbade charcoal-burning near the chief towns. Industries using wood were restricted in their operations; the laying out of new vineyards was prohibited under heavy penalties for centuries; and finally, during last century, the use of uncloven vine-props was forbidden. The exportation of timber took place only under great difficulties, and even the removal of timber from one place to another in Switzerland was, until 1848, very much restricted. In 1376, Zurich forbade clearings to be laid down in pasture, and Fribourg would not allow sheep-pastures to be established in clearings. Goats were not permitted to be let loose in the woods; and rosin-scrapers were excluded from many of the forests. None of these numerous decrees appear, however, to have had much effect, the very number of them testifying to their powerlessness to check the evil.

In 1702, prior to which date attention was paid solely to the maintenance and protection of the timber, the Government appointed a Commission to inquire how the forests might be best preserved, enlarged and improved; and subsequently issued a decree carrying the recommendations of the Commission into effect. In 1725, Berne followed the example of Zurich, and published forestry orders, which contained directions for the cultivation of timber and for permanent improvements. Similarly, in other cantons, improved systems were introduced; the compulsory planting of marshy meadow-land was decreed; a season was set apart for felling, the growth of Oaks was recommended, and the formation of clearings was forbidden. In 1755, an excellent forestry code was drawn up by Joseph Wilhelm, Prince-Bishop of Bâle. About 1760, two scientific societies—the Physical Society of Zurich and the Economical Society of Berne—made great efforts to introduce improved knowledge of woodcraft into Switzerland, and with this object they made strong representations to their respective Governments, and the Forestry Decrees of 1773 and 1786 were the results. The substance of these decrees may be stated to be the surveying of forests, the appointment of officials who would supervise planting, experiment on exotics, and help in teaching a more scientific system of wood cutting. By means of these measures some real progress was made, which, however, was stopped by the general confusion during the beginning of this century; but when peace was restored, the Helvetic Government turned their attention again to the forests, which by this time had suffered severely. Soleure was the first to start a system under which technical instruction was given to two citizens from each woodland district, the better

qualified being chosen foresters. From this time until 1830, forest laws were drawn up universally, prescribing the modes in which timber was to be felled.

In consequence of the disastrous floods in Switzerland in 1830 forest laws were more generally enacted and more rigidly enforced than they had ever been before. The number of officials was increased, and great attention was paid to their training. In fact, the spread of the science of forestry in Switzerland dates from this period. At first the people thwarted the officials in every way, but, becoming gradually enlightened as to the utility of the government measures, they ceased from actual opposition. Even the most backward of the cantons began to realize that their true interests lay in the preservation of the forests, both as a commercial speculation, having regard to the advancing price of timber, and as a support for precipitous ground, and on account of its domestic and national uses.

Hitherto the students trained in forestry had been sent to the schools in Germany, but in 1855 the Confederation established a Forestry School, in which henceforth Swiss students were educated in the art of woodcraft and the kindred sciences. In 1858 a searching inquiry was made into the supposed connection of the forests and the course of the mountain torrents, and, as a consequence, the state aided the School of Forestry in their efforts to plant anew the ground where springs abounded, and officials were appointed for this purpose. With regard to these officials, mention of whom occurs in all the forest laws of Switzerland, we first hear of them in 1314, when, as in subsequent centuries, they were supposed to be aided by the inhabitants, every one of whom in a woodland district was sworn to disclose any breach of the decrees which came to his knowledge. The ordinary forest-keeper was generally nothing more than an intelligent wood-cutter; but when it was seen that some technical teaching was necessary, the skilled man, and, later still, the man with a knowledge of natural science and mathematics, was always preferred. In 1868 the disastrous floods gave a fresh impetus to the spirit of inquiry into the action of the forests on the rainfall and the course of the torrents; and in the revised Federal Constitution of 1874 an article was inserted giving the Federation control over the forests and waterways, and authority to interfere in any way they may think fit. Under this article two officials were appointed—the Federal Inspector of Forests, and also a sub-Inspector. The Forestry Societies unanimously adopted a programme which, being presented to the Federal Council, was embodied in the Forest Law proposed by the Council in 1875. This proposed enactment led to much discussion in the Assembly, but was finally passed by both Houses. The district to be subject to the law included not only the high mountain ranges, but also the hills bordering on the plains, as sharing in the protection afforded against floods and avalanches by the works which were intended to be undertaken in the former. The district included a tract of country in all about sixty per cent. of the whole of Switzerland, or 6,750,000 acres, about 15.8 per cent. of which was forest land. It was decided that the rights of private owners should not be infringed except in case of necessity—that is to say, where the woods of private owners were 'protecting' woods; in other words, where, on account of their position, they might have an influence on the climate, avalanches, landslips, etc. Each canton was required to maintain an efficient staff of officials; and to each individual who had received technical training an area of about 17,500 acres was assigned if in the plains, and 25,000 acres on the mountains. All the woods under official supervision, including, of course, private woods which came under the class 'protecting' woods, were to be demarcated, all clearings were to be immediately planted afresh, and where necessary new forests were to be created, the Federal treasury bearing from thirty to seventy per cent. of the cost, or, in the case of replanting protecting woods, from twenty to fifty per cent., according to the difficulty and the importance of the works, which were always required to receive the approval of the Inspector-General before the Federal subvention was granted. Anything which might endanger the utility of the forests was strictly forbidden; cattle were not allowed to graze, nor could leaves be collected except in fixed spots. To this enactment was added a 'Règlement d'Exécution,' which provides, among other things, for the course of education to be given to each student of forestry by the canton to entitle it to the Federal subsidy. Instruction must be given in the following subjects: (1) Forest-surveying and measurement in detail; calculations of the dimensions and value of single trees, and of outlying tracts of wood; road-making; safeguards against avalanches, etc. (2) Study of the different kinds of timber and of noxious plants. (3) Elementary knowledge of soils, and of

their component parts. (4) Fundamental notions of the laws of climate and meteorology. (5) Cultivation and care of forests. (6) Book-keeping and other general branches of instruction valuable for under-foresters. The Federal Government pay the teachers, who are appointed by the canton, subject to the approval of the Federal Government.

At the outset there were great difficulties in carrying out the Forest Law. There is not now in the cantons a uniform organization for carrying it out; and Dr. Fankhauser, one of the highest officials of the Forest Department, does not think that such an organization is possible, having regard to the differences in position and ideas of the various cantons. At the present time each canton possesses in a measure its own scheme of forestry organization. There are, however, two main systems in existence in the Federal district, the first of which prevails in the central, eastern and southern parts of Switzerland. Each canton is divided into districts of from 17,500 to 35,000 acres each, and over each district the canton places an officer who has received scientific training; under him are the keepers and deputy foresters, chosen by the owners from among the students of the local forestry school, and paid by them. Each deputy has about 3,000 acres to take care of, and has but to carry out the orders of his superior as to felling, clearing and replanting. In the next, however, a different system obtains. Here the country is far less mountainous, and the inhabitants industrial rather than agricultural in their pursuits. In these cantons the district forester has from 7,500 to 17,500 acres under him, and in this district he marks out all the fellings to be performed, and in fact does everything but the manual labor, which he leaves to his inferiors. In this district, where timber is very high in price, and the opportunities of sale numerous, the country is frequently reforested by private individuals, while in the other cantons the state is forced to do nearly everything.

The salaries of the forest officials vary very much in the different cantons, but even in the best paid districts the remuneration is very modest. Under-foresters receive sometimes a fixed salary, sometimes only daily wages when employed. If the former, the sum varies from \$125 to \$250. If the rate of pay is per day, which is unusual, it is generally fixed at \$1. District foresters usually receive from \$440 to \$560 a year. In Uri, however, \$600 is given, and in a few places as high as \$800 per annum. Cantonal forest inspectors receive from \$600 to \$900 a year, besides allowances, which are always given to the higher officials when traveling on duty, with the cost of the journey.

Correspondence.

The New York Chrysanthemum Show.

To the Editor of GARDEN AND FOREST:

Sir.—A flower show is hardly the place to see plants at their best. In the garden, in the field, in the green-house, or even in the living room they look better than when massed together, bottled, labeled, and stiffly contrasted in a crowded exhibition. Of course there is room for improvement in the arrangement of exhibitions—beauty might be considered a little more without any sacrifice in the way of convenience. But as it is we usually feel: These are beautiful things, but how much more beautiful they must be under other conditions.

This is especially true when Chrysanthemums are in question. As isolated blossoms some of them—not all—are very beautiful. But they need number and a particular kind of arrangement to appear at their best; for decorativeness, effectiveness, is their prime characteristic. Nor when we turn from the isolated blossom to the growing plant are we fully satisfied. The rather ragged habit of the Chrysanthemum and the comparative sparseness of its foliage seldom result in a plant which, however excellent from the cultivator's point of view, is a really beautiful object or shows its blossoms to the best advantage. To my mind the right way to see them is cut with long stems and arranged in a tall and capacious vessel. The bunch must be rather large, or the full stateliness of the flower and glory of its color will not appear; yet it must not be crowded together or the beauty of individual blossoms will be lost. Stiffly stuck in moss Chrysanthemums never look well; and massed in a tight layer on a low dish they scarcely look better. No matter how many of them there are the grouping should be light and open, that the combined grace and dignity of the spray with its many heads may not be concealed. And a tall vessel is better than a lower one, as more harmonious with the stately effect they can produce.

Nor is the material of the jar beneath consideration. Clear glass is not desirable, as it is with Roses, for Chrysanthemum leaves and stems seen in the water are devoid of grace; nor should showy colors be permitted, which would detract from the effect of the flowers. Green cut glass, or white or blue and white china, or brass or silver—these are the best possible receptacles. Usually the bunch can be so graduated that its own foliage will suffice; but in no case should very delicate foliage be added, for the Chrysanthemum is certainly not a delicate flower. Of course as Maiden-hair Fern is now so high in favor it is often used with Chrysanthemums; nothing can be much more inharmonious than its effect, yet a basket thus composed took a second premium at the recent exhibition in New York.

But if a lover of beauty could tie his attention down to individual blossoms a wonderful amount of enjoyment awaited him in this exhibition. It seemed as though Nature herself might there acknowledge man's supremacy, seeing what he had made out of the suggestion she gave in her first Chrysanthemums. What splendid miracles of development he had brought about, and along how many different lines! There were no true scarlets among the endless colors, but there was every other kind of red and brown and pink; many purples, scores of yellows; no blues, but some yellows that were almost green; and whites in infinite variety. And now these colors were pure and solid, now flashed and streaked in the most indescribable ways; and now the one ruled on the under side of the petal, a quite different one above, and yet each kept its perfect purity. Anything more gorgeous than the contrast of red and yellow thus produced in the Mrs. Wheeler, or anything more brilliant than the flashed red and orange of the Lord Byron, it would be impossible to find; while I thought I had never seen a flower of so rare and exquisite a pure yellow as the Golden Dragon. As to size, there was everything, from things as small as a gold button to things almost as big as a Cabbage. And shapes differed as widely. Some were as flat as a plate, some as round as a ball; some as solid as Artichokes, some so fragile they looked as though a breath would blow them apart. There were flowers with large, strong petals, and flowers with delicate, thread-like petals; with short ones and long ones, straight or spirally twisted, curling in or curling out, or lying in a flat row around a solid centre. There were Chrysanthemums like little English Daisies, and like Peonies, and like Sunflowers, and others that one could hardly tell from Dahlias, and others, again, that suggested nothing in the world but Chrysanthemums determined to be as eccentric as they could. It was amusing for a while to try and pick out the most beautiful ones, but the attempt was soon abandoned in despair, for there were so many types one's standard of beauty changed at every step.

Of the three great novelties of the year, Mrs. L. P. Morton may be a great triumph from the cultivator's point of view; but from that of the mere "lover of loveliness," it seemed a failure—not pleasing in its color, which is an impure pink, oddly variegated with a dull white, and in disagreeable contrast with the greenish-yellow centre; and not pleasing in its form either—which resembles that of a half-double Sunflower.

The Mrs. Carnegie, on the other hand, is superb—a perfect expression of the incurved type, neither so full as to be hard nor so loose as to lose form and dignity; variable in its manner of growth, moreover, so that no two blossoms are identical in shape, while all are beautiful; of the most magnificent dark-red shade, and truly wonderful in size. But the most beautiful of all—the most beautiful Chrysanthemum that exists—is the famous Mrs. Alpheus Hardy. Here again is the incurved type, a little fuller than in the Mrs. Carnegie, but not too solid, and not in the least stiff or artificial looking. The color is the most pure and radiant imaginable white, and the singular down on the petals adds much more than one might imagine to their beauty. This down is called "hairs," I believe, by scientific writers, or even "a glandular growth." But it is down to the eye of ignorance, and the petals look like nothing so much as the tufts which grow at the base of the wing of a swan. It has often been said of Chrysanthemums that the best of them lack the indefinable quality we call charm. They are splendid flowers, beautiful flowers, but devoid of sentiment, not charming, not poetical. No one will say this again who has seen the Mrs. Hardy. Just the addition of this downy covering to its pure white petals gives it delicacy, charm and sentiment; makes it as poetical as a Water Lily or a Rose.

George Fleming.

[Our opinion as to the merit of these novelties has

been already expressed. The flowers of the Mrs. L. P. Morton were cut from the original seedling plant, and the variety promises to be of good form and color. The Mrs. Alpheus Hardy is most interesting as a novelty. Unlike many novelties, too, it has a distinct and genuine beauty. We should hesitate, however, before pronouncing it the most beautiful Chrysanthemum in the world.—Ed.]

Paulownia Imperialis.

To the Editor of GARDEN AND FOREST :

Sir.—In 1876 I purchased a strong root of this tree and planted it in good soil with an eastern exposure, quite well protected on the west and north. The object was to confine the annual growth, from year to year, to a single stem. It made a growth of eight feet the first summer, which was cut back nearly to the ground the next spring. As soon as the buds had pushed, all but one were rubbed off. By June 1st this had made a growth of one foot. Afterwards, to ascertain its rate of growth, it was measured on August 5th and again on the 12th. The growth was precisely thirteen inches. September 23d the stem had attained a height of fourteen feet, and measured, at a foot from the ground, three inches in diameter. The massive petioles averaged sixteen inches in length and nearly an inch in diameter. The leaves were about nine inches apart, and the largest measured ten feet three inches across. All of them were nearly as large, except those at or near the top. Those splendid leaves stood many a hard wind without being much torn. The shoot towered up, during the middle and latter part of the season, above the surrounding foliage—a singularly odd and by no means unattractive object. Year after year, either in the spring or fall, this shoot of the preceding season's growth was cut off near the ground. In 1878 it made a growth nearly as great as in 1877, but during every succeeding year the growth was shorter, until, in 1887, the stump put forth a feeble shoot or so, which perished in a few weeks, and the plant was dead.

The above notes may interest those who read Professor Penhallow's remarks respecting the Paulownia in GARDEN AND FOREST of October 17th, page 406: "The Paulownia was planted (Montreal, Canada) in October, 1881. The stems have been killed to the ground each year, but the growth of each season has proved larger than that of the preceding, and this year reached a height of ten feet. The roots, which are quite hardy, appear to be gaining strength each year, and the plant is quite as well established as the one growing in the Botanic Garden at Cambridge."

I fancy, from my own experiment, that the Paulownia will not stand being cut or frozen back many years in succession.

Bergen County, New Jersey.

E. S. Carman.

Horticultural Exhibitions.

The Short Hills Orchid and Chrysanthemum Show.

THIS exhibition was really the formal opening of the United States Nurseries at Short Hills, New Jersey, and the fact that plants were displayed at home instead of being staged in a public hall, gave it an additional interest to professional visitors. The eighteen houses already built were filled with vigorous plants arranged with much taste and skill. This collection is already remarkable for Cypripediums, of which it includes 360 species and varieties, many of them rare or unique. Masses of *C. insigne*, in its various forms, filled the first house, among them being *C. insigne Chantinii*, superb in shape and color, Philbrick's famous variety, and an extraordinary novelty with a corrugated lip, the upper part of the pouch being fluted in a most interesting way. Next to these were forms of *C. Spicریانum*, of which the variety *nigrescens* is noticeable for the rich dark color of lip and petals. Here, too, were *C. Leeanum*, one of the rarer hybrids, many examples of the beautiful *C. Harrisianum*, *C. leuchorrodium*, *C. Dayanum*, *C. dilectum*, *C. Haynaldianum*, *C. Calunum*, *C. Morganiae*, *C. Io grandis*, and *C. Arthurianum*.

Near the Cypripediums was the beautiful yellow variety of *Odontoglossum Rossii*, this plant, we believe, being found only in the Short Hills collection. Flowering specimens of *O. crispum Alexandra*, *Oncidium Cramerii*, and the fragrant *Zygopetalum Mackayii* were grouped near each other. Few *Lælias* were in flower except a very dark form of *L. Autumnalis* and the delicate little *L. Eyermanii*, the new hybrid of American origin. *Oncidium splendidum*, somewhat injured

by previous exhibitions, was still interesting, since it so rarely blooms. Other well-flowered *Oncidium*s were *O. ornithorhynchum* and *O. incurvum*. A collection of *Lycaste Skinneri* showed all the varieties from crimson to pure white.

Next in importance to the Orchids were the stove plants, and foremost among these was the great display of Anthuriums. A collection of these plants lately secured from a Swiss grower includes specimens in the flowering section which are unique and as yet unknown to commerce. Crotons, Nephthes, Dracenas and Ferns fill up other houses, some of the specimen Crotons being unusually fine. The cool houses showed a wonderful array of *Primula obconica*, and there was a houseful of good Cyclamens.

The Chrysanthemums alone would have sufficed to make an exhibition, but the chief attraction was a houseful of the Mrs. Alpheus Hardy, which has been so often described. The flower shows well in a great mass, although its absolute purity of color produces an effect that is almost dazzling, but visitors never seem to tire of admiring it.

Large numbers of professional and amateur horticulturists, some of them from distant states, visited the exhibition during the week, and Messrs. Pitcher & Manda are to be congratulated on the uniform admiration expressed for their establishment and all its appointments.

Autumn Flower Show in New York.

MESSRS. SIEBRECHT & WADLEY have been successful in their venturesome experiment of holding a flower show at this season in which the Chrysanthemum is not the chief attraction. The collection at the Eden Musée consisted mainly of plants used for decoration, and they were grouped with striking originality. The prim little Japanese Garden, with hedges of Arbor Vite and graveled walks, beds of Roman Hyacinths, Pansies, Marigolds, Carnations, Stevias, Cylamens and Primulas, interested many visitors. Many neat effects were produced in the recesses along the walls, one nook being filled with well-grown Heaths, another with dwarf Orange trees, some with Orchids, others with stove plants, while Nephthes and Stag's-horn Ferns were hung about to the best advantage. A splendid specimen of *Livistonia horrida* made a fine background for one of these groups, and other show plants, like the great *Cyathea dealbata* and the wonderful *Alsophila*, a pair of superb *Seaforthias* and a fine *Areca lutescens*, were effectively placed amid a bewildering abundance of tropical rarities. Besides the profusion of Orchids and decorative plants, cut Roses of the more fashionable varieties and of exquisite quality were scattered among the Ferns, and in addition to the ever-present and always admired Mrs. Hardy, there were some excellent Chrysanthemums. Mr. John Henderson, Mr. Barr, of Orange, and Wm. Tricker, gardener to Judge Benedict, sent many of the best of these. The flowers of Mrs. Jessie Barr, a white of superb form and substance, Sunset, which is worthy of its name, Gold Lace, an odd lacinated yellow, and Mrs. Munn, a duplication of Mrs. Frank Thompson in creamy white, were the most striking.

The exhibition was well attended, especially by people of fashion. Very rarely has there been collected and displayed in this city so great a variety of choice plants in such excellent condition.

Recent Plant Portraits.

TEA ROSE, COMTE HENRI RIGNON, *Journal des Roses*, September; a handsome, free-flowering hybrid, with pale copper-colored petals, delicately shaded with rose-salmon on the margins.

LÆLIA PURPURATA, *Revue de l'Horticulture Belge*, September.

AZALEA INDICA, MISS E. JARRETT, *Revue de l'Horticulture Belge*, September; a variety raised in the Van Houtte nurseries, with very large single white flowers, faintly tinged with green; evidently a plant of very considerable merit; it received the first prize at the quinquennial exhibition at Ghent in 1883.

PITHECOCTENIUM BUCCINATORIUM, *Bulletino R. Soc. Toscana di Orticultura*, September.

ACALYPHA TRIUMPHANS, *L'Illustration Horticole*, August 31st.

PHALÆNOPSIS SCHILLERIANA, *L'Illustration Horticole*, August 31st.

DENDROBIUM MACROPHYLLUM, *L'Illustration Horticole*, August 31st.

VRIESEA WITTMACKIANA, *Gartenflora*, October 15th; a hybrid between *V. Barilletii* and *V. Moneniana*, these two species appearing also on the plate.

SYRINGA EMODI ROSEA, *Revue Horticole*, November 1st.

Notes.

A feature of the recent Pomological Exhibition in Vienna was a special display of fruits ill adapted to local cultivation, and labeled "warnings."

The death is announced of a famous Dutch horticulturist, Joshua Valk, who for no less than fifty-seven years was connected with the botanical garden in Leyden.

The shipments of Beans from southern California to eastern cities has already reached fifty car-loads. Orders are still coming in, and there is likely to be a brisk movement of the crop eastward for two months to come.

The Marshall Pear is a comparatively new variety, which ripens some ten days later than the Bartlett. Specimens of the fruit received from Mr. P. H. Foster, of Babylon, Long Island, were bell-shaped, of good size, with a smooth, thin skin, which is beautifully russeted. The flesh is white, juicy, and of excellent flavor. The tree is said to be vigorous and productive, and altogether the Pear seems to be a real acquisition.

It appears from a recent issue of the *Southern Lumberman*, published in Nashville, that the soft, spongy wood of the knees, peculiar growths upon the roots of the Southern Cypress (*Taxodium distichum*), is sometimes manufactured into razor-strops, which are pronounced more effective than the leather-covered, stiff strops in general use. It is necessary, however, to keep them protected from dust, which adheres readily to the soft wood, and soon becomes embedded in the grain, ruining it for this purpose.

At the late Chrysanthemum show in Philadelphia, Mr. W. K. Harris exhibited a plant upon which twenty distinct varieties had been grafted and all were in bloom at the same time. This suggests a new line of work, inasmuch as such plants would be objects of great popular interest at exhibitions, if a proper selection and arrangement of colors were made. It may be questioned, however, whether a plant bearing several different kinds of flowers possesses any value except as a curiosity. Whether some varieties of feeble growth would be improved if grafted on a more robust stock can be ascertained by experiment.

A memorial to Alexander Humboldt was recently erected in the so-called Humboldt field, one of the new parks of Berlin. As a statue of the great naturalist already stood in the centre of the town, the new monument was given a very different form. From all parts of the Province of Brandenburg the largest possible erratic stones (glacial boulders) were brought together and arranged in imitation of a terminal moraine. In their vicinity curious stones of many other sorts are grouped, and one bears a simple inscription telling that the "monument" was erected in Humboldt's honor by the city of Berlin. Our correspondent, Dr. Bolle, has long been actively engaged in forwarding this movement.

Mr. C. S. Burt, President of the Bourbon Lumber Company, of Baton Rouge, La., lately informed a correspondent of the *St. Louis Lumberman* that his company are at present dragging, from a swamp to one of their mills, a number of cypress logs felled by General Jackson's army in 1812, and used at the time for closing the Manchac River. Mr. Burt says the bark and sap have rotted off from the logs, but that the heart wood is as good as ever, and the finest quality of lumber is obtained from these logs. The *St. Louis Lumberman* has on exhibition in its office a cypress picket top from Baton Rouge, La., which was exposed to the weather sixty-three years, without showing marked signs of decay.

It has sometimes been stated that the worst monstrosities in the way of formal planting which disfigure some of our western parks—figures of men and animals and even portraits of various celebrities—should be charged to the bad taste not of native American, but of German, gardeners. The statement seems to find some support in the fact that at a horticultural exhibition held not long ago in one of the smaller German towns, a portrait of the Emperor William I., four feet and a half high, was displayed in bright-leaved plants; and in the further fact that none of the parks of our eastern towns, except in Pittsburgh, where German influence is less strongly felt than at the West, are deformed by similar horrors.

The importance attached to landscape gardening enterprises abroad is shown by the fact that when it was proposed last year to alter and enlarge the public park at Lisbon an international competition was opened for the purpose of secur-

ing the best possible plan. Large prizes were offered for the three most satisfactory plans, which were to become the property of the municipality. After the jury had made its preliminary selection, twenty-six plans remained in its hands, among which the final choice was made. The first prize was awarded to M. Henri Lusseau, the second to M. Henri Duchêne, and the third to M. Eugène Deny, all being French artists. Two French and one German artist received honorable mention. Moreover, a pamphlet, carefully prepared by a distinguished French expert, was published, in which the nature of the problem and the character of the designs submitted were fully explained by the aid of numerous drawings.

Prince Schwarzenberg, who recently died in Vienna at the age of eighty-nine, was the most conspicuous and influential of the many Austrian noblemen who have concerned themselves with horticulture. He was chiefly instrumental in the establishment of the Imperial Horticultural Society, and its first exhibition—the first flower-show ever opened in Austria—was held in his green-house in the year 1827. Elected the first President of the young society, he held the position until his death, a period of sixty years; and during all this time devoted himself with the greatest energy and amiability to furthering its interests and exciting a love of the gardener's art in his fellow-countrymen at large. His beautiful grounds were freely opened to the public, and special exhibitions were often held in them. The last exhibition he arranged, during the summer of this year, was to display his beautiful collection of Gloxinias, a flower which, according to the testimony of German journals, is not yet as well known in that country as with us.

A recent number of *Gartenflora* reproduces from Professor Schuebler's work on Norwegian trees—"Viridarium Norvegicum, Norges Vaextrige"—an illustration of a curious "Recumbent Birch-tree," which stands, if the word is appropriate, on a mountain side about three miles from Christiania. The trunk is something over six metres in length and thirteen centimetres in diameter a foot above the roots. Upon leaving the ground it bends towards the left, running horizontally for a short distance; then it makes an abrupt reverse turn and runs towards the right close to the surface and partly reclining upon it. Near the elbow thus formed a branch rises erect in the shape of a normally-formed tree, with a tall, slender trunk. Five similar branches succeed this at regular intervals in similar tree-like development, the last forming the turned-up termination of the recumbent trunk. As there is no trace whatever of minor branches, the effect of these six separate trees springing, seemingly, from a dead log, is extremely curious. The first in order is about fifteen feet in height and the others graduate down by regular degrees. The trunk must have been prostrated in very early life, and the branches assumed their singular shape—at once normal and abnormal—through the natural action of what the German paper calls "negative geotropism."

The success and usefulness of the Botanical Garden in Adelaide, Australia, are made very plain in the recently published report of the Director, Dr. Schomburgk. The garden was founded in 1855, and at first included only forty acres, originally an open forest of huge Eucalyptus trees, covered in the rainy season with a thick undergrowth. Fifteen acres were laid out as a little park, with lakes and brooks and a little hall for horticultural exhibitions. Now this park has been enlarged by the addition of forty-eight acres, and the whole garden includes 140 acres. A large palm-house has recently been built; water is abundantly supplied from the town reservoirs; a Museum of Economic Botany has been constructed, and a botanical garden planted. The cost of maintenance is less than £5,000 a year, while the utility of the establishment can hardly be overrated. It supplies a charming place of popular resort in a climate where such a place is especially required; and it has largely served the practical interest of the province by experiments in cultivation and by the distribution of plants and seeds. Vines have been imported from France, and their usefulness in Australia tested; Sorghum has been introduced; Guinea grass (*Panicum giganteum*) has been proved well adapted to local culture, and Ramie or China Grass (*Boehmeria nivea*) has been proved unsuitable. During the special Jubilee Exhibition held last year 12,973 different species of plants were shown; among those in the green-houses were 180 species of Palms, 396 Orchids and 465 Ferns. The highest temperature recorded in the garden during 1877 was 111.2 degrees Fahrenheit in the shade; and the amount of rainfall was 25.7 inches, a remarkable quantity, for in the previous year only 14.4 inches had been measured.

Natural Beauty and the Landscape Gardener.

IN the *Century Magazine* for October was an interesting article called "An English Deer Park," by Mr. Richard Jeffries, a well-known writer on the beauties of nature, who died, we believe, before his words were in print. Chief among the attractions of the fine park to which he refers—without giving us its name or indicating its locality—is its naturalness of aspect. "Happily," he says, "the place escaped notice in that artificial era when half the parks and woods were spoiled to make the engraver's ideal landscape of straight vistas, broad in the foreground and narrowing up to nothing. Wide, straight roads—you can call them nothing else—were cut through the finest woods, so that upon looking from a certain window or standing at a certain spot in the grounds you might see a church-tower at the end of the cutting. . . . Many common highway roads are really delightful, winding through trees and hedge-rows, with glimpses of hills and distant villages. But these planned, straight vistas . . . at once destroy the pleasant illusion of primeval forest. . . . Happily, this park escaped, and it is beautiful. Our English landscape wants no gardening; it *cannot* be gardened. The least interference kills it. The beauty of English woodland and country is in its detail. There is nothing empty and unclothed. . . . Nature is a miniature painter, and handles a delicate brush, the tip of which touches the tiniest spot and leaves something living. The park has indeed its larger lines, its broad, open sweep and gradual slope, to which the eye accustomed to small inclosures requires time to adjust itself. These left to themselves are beautiful; they are the surface of the earth, which is always true to itself, and needs no banks nor artificial hollows. The earth is right and the tree is right; trim either and all is wrong."

These words have doubtless been read by many of our readers; and as they are prettily written and savor of that "love of nature" which most people are apt to think

means the same thing as a love of the beautiful in nature, they have perhaps deceived many into agreement with the ideas they voice. We are glad, therefore, to be able to quote from another English writer (in the pages of *The Garden*) an excellent statement of what we conceive to be a better point of view in such matters. Criticising the paragraph we have cited, this writer says:

"Our best natural landscapes certainly want but little gardening, but it *is* possible to garden them. The least *interference* with Nature always kills it, as Jeffries wrote; but, then, a little assistance—a little enrichment—is sometimes better than the 'masterly inactivity' which he seems to recommend as everything. Man likes to adjust himself to Nature, and often must do so, while the true gardener can help Nature wield her paint-brush, and he will also touch the tiny spots and leave 'something living' and beautiful wherever he goes. The great landscape gardener merely helps Nature to do her work quickly and easily, and that he can do so is past all doubt. Throwing up unnecessary terraces and scooping out unnecessary ditches over which unnecessary bridges are thrown is not gardening. If Nature puts a brook or a river, then the bridge is a real human want, and may be supplied with good effect: rarely or never can it be done otherwise. It is not in doing things that the landscape gardener's art is most fully illustrated. Some of his greatest triumphs have been achieved in knowing exactly what to leave alone."

But even these words would not leave upon a reader's mind exactly the impression which we conceive to be the right one. The right impression with regard to landscape-gardening we conceive to be this. There are very many beautiful spots on earth, but very few of them are beautiful in a way that fits them, untouched by art, for association with the homes of men. A primeval forest would be a priceless possession on some distant part of an estate; but to permit it to come up close to a splendid dwelling would be an offense against appropriateness and harmony, and therefore against beauty. A forest is not a park, and to make a park art is needed. Whether it is made by a process of addition or by a process of subtraction matters nothing. It needs as much art to disengage a beautiful landscape from encumbering details as to create one from the beginning. If certain English landscapes are so beautiful, and at the same time so appropriate for dwelling-places, that it seems sacrilege to touch them, it is because man has been at work over the whole surface of England for many centuries. Primeval effects nowhere exist where the country wears its typically English look. In our own land we seldom find English landscape effects near where we wish to build our homes. The reason is obvious, and so likewise is the necessity why we should be more careful than the English to call in the aid of art.

Moreover, while in the majority of cases those natural effects which Mr. Jeffries loved are the best ones to desire, there are certain cases when the straight roads he condemns are very beautiful, and when formal features of other kinds may well accompany them. Everything depends on appropriateness and harmony. What is good in one case is bad in another; and no computation of the average number of cases when a thing is good or is bad can help to determine its excellence when a given problem is in view. And finally, it will be confessed that in certain places where men must live Nature is not beautiful. Then the artist may well interfere with her intentions and create a loveliness of his own. Then he may make brooks and rivers if he can induce her to help him, and alter the surface of the ground, and decide what trees shall grow upon it and where. In short, it is only a question of degree. Everywhere and always the artist is needed. He has first to decide whether much or little should be done, and then to decide in what manner it should be done. If he does not understand the art of gardening he will create ugliness, not beauty; but this is not to say that the art itself should be condemned.

THE list of the writings of the late Professor Asa Gray, chronologically arranged by his associates, Professor Goodale and Mr. Sereno Watson, have been reprinted, in pamphlet form, from the *American Journal of Science*, in which they formed the appendix to the thirty-sixth volume. The long list, which occupies forty-one pages of the *Journal*, is conveniently divided into three series—the first being devoted to “Scientific Works and Articles;” the second to “Botanical Notices and Book Reviews;” and the third to “Biographical Sketches, Obituaries, Necrological Notices,” etc. Asa Gray was born in 1810, and his first contribution to science was published in 1834, and, curiously enough, was devoted to mineralogy, a subject in which he was early interested, but soon abandoned entirely. His publications, thus early begun, were continued almost up to the hour when he was struck down with the illness which ended that long and brilliant career, which is the pride and glory of every educated American.

In a period of fifty-three years, in 1839 only is there no entry of a publication from his pen. The book notices and reviews were begun in 1841 in the *American Journal of Science*, with an account of a “Report on the Tea Plant in Upper Assam,” and were continued, uninterruptedly, with the exception of the year 1851, until the winter of 1887. Taken as a whole, they furnish the best account of the history and development of the science of botany and of botanical literature during this period which has ever been written, just as the biographical sketches and necrological notices, begun in 1842 in the *American Journal of Science*, give the best account of the principal figures which passed from the botanical stage during a period of great botanical activity, in which Charles Darwin was changing the whole current of scientific thought.

The number of Professor Gray's publications, as displayed in this list, and the immense and varied field which they cover, must appear stupendous, even to those persons who were best fitted by opportunity to judge of his vast knowledge, his wonderful mental activity and surprising industry; and the astonishment will be all the greater when it is remembered that his work was of the very highest class, and that it was coupled with constant and engrossing professorial and administrative duties.

The value of the chronological list is greatly increased by the addition of a very complete index, occupying no less than twenty-five pages, of two columns each, prepared by Mr. A. B. Seymour. The list, thus supplemented, will be found invaluable by all working botanists, especially those interested in American plants, but, unfortunately, the papers to which it serves as a guide are widely scattered in publications which are practically inaccessible to the ordinary student. The time, however, is not, it is to be hoped, very far distant, when Professor Gray's scattered papers, and especially the bibliographical ones, if they cannot all be republished, will be gathered together and reproduced for the benefit of botanists.

No more useful, appropriate or enduring monument, with the single exception of a permanent endowment for the support and increase of his vast herbarium—the great controlling interest of his life—can be erected to the memory of Asa Gray.

A Park Commission of twenty-one members has been formed at Rochester, New York. Among them we note the names of the Roman Catholic Bishop of the Diocese, Doctor McQuaid, Mr. William Barry, of the Mount Hope nurseries, and Mr. William Kimball, who has one of the finest collections of Orchids in the world. The number of commissioners is excessive, but the board has already taken two steps from which we should infer that its work would be unusually well done. First, it has elected as its President an eminent physician and sanitarian, Dr. Edward M. Moore, the President of the State Board of Health of New York; second, before acquiring any land it has separately taken the professional advice of eight men of

experience in the management of public parks—Mr. H. W. S. Cleveland, of Minneapolis; Mr. Calvert Vaux and Mr. Samuel Parsons, Jr., of New York; Mr. F. L. Olmsted and Mr. J. C. Olmsted, of Brookline; Mr. William McMillan, of Buffalo, and Mr. W. S. Edgerton, of Albany. It has occasioned some surprise that each of these gentlemen, after making the circuit of the city, should, without conference, have fixed upon the same three localities as most desirable to be secured for park purposes. One of these is a body of high ground commanding a superb distant prospect, a part of the site being a tract of land of fifty acres which Messrs. Ellwanger & Barry, the well-known nurserymen, have presented to the city; another, a piece of the celebrated Genesee meadows above the city; the third, a portion of the great wooded gorge of the Genesee below the city.

A French pomologist, Monsieur H. Beer, has established at Louveciennes, not far from Paris, an experimental fruit-garden, in which 4,000 Apple and Pear trees have already been planted, among which are many American varieties scarcely known yet by name even in France, but which are now to be tried upon a sufficient scale to test satisfactorily their merits. With these Monsieur Beer has imported from this country plants of some of the earliest and best known varieties of French origin with the view of determining whether these varieties have undergone any change in the character of their fruit during the period they have been subjected to the American climate and to the American methods of cultivation. The result of this experiment will be watched with much interest by pomologists here and abroad.

Newport.—II.

THERE is as much variety among the fences at Newport as among the houses, and the fact is very conspicuous, as properties are so small that one form of barrier is perpetually giving place to another. It can hardly be said that a fence which seems exactly right often appears; sometimes it is too pretentious, more often, perhaps, not dignified enough. In at least one case we find a massive stone wall, some eight feet in height, which would be admirable for the protection of a large park, but seems out of place encircling a few acres in a thickly built settlement, and sins against that neighborly freedom of prospect which is beauty's sole salvation in such a settlement, and is generally preserved at Newport. And in many cases we see, on the other hand, a cheap wooden paling, without dignity or beauty, surrounding expensively kept grounds and a house of the most costly kind. But here and there we find admirable devices. For one of the best we must look again to Mr. Goelet's place, which has a very low, but broad, stone wall, built of rather thin slabs of slate in a way which hits just the right medium between over-precision and carelessness. A rustic fence recently put up on Bellevue Avenue is very well designed and pretty, but perhaps a little too rural in effect for just this situation. Low brick walls are sometimes used, but I saw hardly any which had the beauty possible to this material. Hedges, and especially those of Privet, grow luxuriantly at Newport, and are often employed. Without exception they are well tended, but sometimes they have been allowed to grow so thin that the eye can penetrate them everywhere. No matter how neat a hedge may be, it is certainly a failure when this is the case.

With entrance-gates the case is the same; sometimes they are too mean in effect, sometimes self-assertive and showy beyond all reason. Perhaps the most satisfactory is the fine, tall gate, with wide, lateral wings, of wrought iron, which admits to Mr. Van Alen's new house. It is of Spanish workmanship, and, from the design, seems to date from the middle of the last century; but fashions so often persisted in iron-work after they had died out in architecture, that it is hard to feel sure of its exact time. The pattern is at once strong and very light, and the gate is just what it should be to stand at Newport—very elegant, yet comparatively simple, and not at all suggestive of mere display or of excessive powers of protection. It is to be hoped that it may inspire others to employ this beautiful material. Iron-work as good as this in design, and better in execution, can easily be obtained to-day in America. Better in execution, I say, for last-century iron-work is a combination of welded and riveted pieces, while our best, like that of still earlier centuries abroad, is welded

throughout, and therefore more durable. Nothing better for a Newport wall could be imagined than a low plinth of brick or stone, surmounted by a light iron trellis. The idea struck certain owners some years ago; but that was the age of cast, not wrought, iron; and the results are by no means what they would be if well executed according to our present lights.

The oftener one visits Newport, the more one is impressed with the beauty of the Casino, built, like Mr. Goelet's and Colonel Edgar's houses, by Messrs. McKim, Mead & White. Here, indeed, is something we may be willing to show a foreigner as a measure of our good taste and of our success in artistic independence. In its erection a wholly new problem was triumphantly mastered. It has no prototype in this country or in any other, yet it is so perfect that we can hardly believe it was not the final outcome of a long series of tentative efforts—so appropriate to place and purpose, so consistent from end to end yet so varied between part and part, so thoroughly artistic, so delightfully pretty. If there is anything it needs, it is the more careful planting out of the fences in the second court. These might easily be made to disappear behind vines and shrubberies, and the charming effect of seclusion which reigns in the first court be thus reproduced, in a different way but with the same completeness. Otherwise the planting is excellent. There are trees and shrubs enough, yet not too many, and no formal beds except in just the right spots. The wide lawn in the first court is free from their intrusion, but on either hand, as one enters the gateway, filling the angle between the front building and the wings, is a large, gracefully designed, and pleasingly-colored bed. Thus closely connected with architectural forms, and in a place palpably artificial (in the best sense of the word) from end to end, no features could be more appropriate; and they give just the needed amount of bright color to the softly verdurous general effect.

The most interesting work now in progress at Newport is the laying-out, under Mr. Olmsted's direction, of Mr. Frederick Vanderbilt's place, which occupies a point on the cliff at the turn of Bellevue Avenue. The Cliff Walk, just after bending from a southerly to a westerly direction, here swerved a considerable distance inward to skirt a rocky ravine with steep sides, which breaks the line of the cliff. To regain the space it occupied, and carry it to a more agreeable distance from the house, a bridge has been built over the ravine quite at the edge of the cliff. Lying, I should guess, about thirty feet above the water, which breaks in beneath it over a rock-strewn bed, this bridge is of the simplest possible construction, with small irregular voussoirs in a single round curve. But for this very reason it is both appropriate to its place and admirably picturesque; and the way in which passers will be relieved against the sea and sky, when seen from the house, will make their passing an advantage to the scene rather than an annoyance. I am told that the owners are considering whether it will not be well to adopt a scheme for treating their grounds which will be an entire novelty in this part of Newport. This scheme would confine the lawns and garden shrubberies to the entrance side of the house, and treat the entire seaward slope in the most natural possible way. This portion is largely composed of visible rocks in varied shapes of the most interesting and picturesque character, and it certainly seems as though to plant it with low native shrubs and creepers and wild flowers, simulating, as far as possible, a spot which has not been planted at all, would be the best device. If the house stood farther from its neighbors—on a portion of the shore where conventional, gardenesque treatment has not yet intruded—there could be no possible question about the matter. But it has been objected that just here, with conventional methods of treatment on either hand, harmony will be injured by any deviation from such methods. The place has, however, a comparatively wide reach of water front, and, lying on a point, is isolated from its neighbors to an unusual degree; the ravine, the bridge, and the beautiful rugged rocks seem to demand a picturesquely natural arrangement of its surface; and I think it is certainly to be desired, if one loves either the best kind of beauty or the truest kind of appropriateness, that the new idea may be carried out. But only if there is to be no attempt at compromise. The scheme should be natural throughout or gardenesque throughout. A striking witness to the futility of trying to combine the two results is already shown on that portion of Ochre Point where, on the seaward side of the Cliff Walk, the space is broadest and the rocks are most conspicuous; and it would be a thousand pities were this, perhaps the most beautiful spot on the whole Cliff Walk, to be mutilated in a similar way.

Mr. Olmsted's hand shows again in the drives which, within the past two or three years, have opened up the interior of the

southern portion of the island beyond the districts thus far built upon and behind the Ocean Drive. Here the ground is hilly with bold and beautiful high rocks, offering building sites of a very desirable kind—with no sea fronts, it is true, but with the most superb distant views of land and water. The new roads are admirably disposed for convenience and beauty; but it is a matter of regret that the spaces, usually of triangular form, which are formed here and there by their inter-sections, should have been carefully turfed and planted in a conventional way with young trees and shrubs. Rough grass and Huckleberry bushes and Sumach would have been more in keeping with the character of the landscape as a whole. It is to be hoped that those who may hereafter build in this neighborhood will carefully and artistically preserve its character, and not strive to subdue its rugged and individual charm to that neat prettiness which prevails in the level districts nearer town.

M. G. Van Rensselaer.

New York.

Chinese Horticulture in New York.

AN experiment in Chinese vegetable gardening near New York has established results of some consequence in the course of four years. This industry is conducted with increasing extent on Long Island, chiefly at Woodhaven and at Astoria, with the section including Ravenswood and Steinway, at short distances beyond. The product from these novel gardens, which are known as the *Far yuen*, is already a considerable item as a market supply. It fairly provides for a class of consumers who prize their native vegetables as people accustomed to a largely vegetable diet and who may obtain in New York no less than twenty Chinese varieties of vegetables fresh from western soil.

The *Foo qua* is one of the most abundant of these products seen in market. This is the *Momordica Charantia* or Balsam Pear, sometimes identified erroneously with Egg Plant, and being in other cases confused with the Cucumber, the *Wong qua* of the extended list of edible plants familiar in China. Like the Balsam Apple of the East Indian species of the *Momordica*, this is a curious trailing plant, with ornamental foliage and peculiar fruit. Its intertwining, matted vine, covering the ground on which it grows, is dotted with small yellow flowers, unfolding continuously until late in autumn. Its fruit, which is sold by weight, resembles the Cucumber in size and general contour. The surface is marked thickly with rounded, oblong formations of varied sizes, raised somewhat like embossed patterns in decorative work. The seeds, in the form of little discs, are figured on each flattened side, as with engraved designs. These are perfectly ripened in Long Island Chinese gardens, where they are dried for use in wide, shallow forms of baskets. The sliced fruit, dried in a similar manner, is a medicinal provision. The *Foo qua* is a specially valued product as used in gastronomical combinations of varied nature. Whether fried with chicken, to form an epicurean dish, or chopped and mingled with pork or cooked in some extraordinary manner with codfish, it is equally the delight of Mongolian consumers.

The *Sing qua* is another of the ornamental Gourds with remarkable fruit not unfamiliar to botanists. This is included in the genus *Luffa*, of which ten species have been described. It was formerly classed with the *Cucumis*, from being found allied with it in some of its characteristics. The *Luffa acutangula* is the Chinese variety introduced; the fruit is produced in abundance for the market. In its general shape this is somewhat like the long-necked Gourd, but with ten sharp exterior ridges distinctively marking it in the direction of its length. Its luxuriantly growing vines are trained over poles and trellises, forming lengthy masses of foliage. The yellow flowers continue to appear in the autumn season with the well-developed fruit, which is fully ripened in tropical latitudes only. This product, which is of a sweet taste, is largely used for soup in Chinese cookery, and, in other cases, is prepared like Squash. When very young it may be eaten uncooked, like Cucumbers. As with other varieties of its species, the inner portion of the fruit is spongy, and, when old, forms what may be used as a sponge. The one variety indigenous to this continent is largely represented in such form in the shops. The network formation of the inner substance of the fruit when ripe, is sometimes eighteen inches in length and three inches in diameter. From recent experiments this fruit, known popularly as the Sponge Cucumber, and variously as the Cloth Gourd, the Towel Gourd, the Bonnet Gourd and the Egyptian Bath Sponge, has been brought nearly to maturity near New York from seeds planted in the open ground. The product in the variety reaching Chinese gastronomists in New York amounts to several hundred pounds a year.

A vegetable in great demand is the Mustard Green (*Quon qua*), which is obtained in large additions in pickled form among Chinese importations. This is greatly prized for its flavoring quality in the composition of varied soups and stews. A kind of green, growing like a Lily, in the water, is the *Own choy*, with a triangular form of leaf and a hollow stalk like the Bamboo. A variety known as *Yen choy*, meaning lamb's quarter, is cultivated, and the *Bie choy*, the white-green, with green top and white stalk, is another of this series. The *Tong choy* and the *Long na boe*, or snowflake green, are additional varieties on trial.

The *Ho lan doe*, or Sugar Pea, is satisfactorily developed for the market, and the String Bean, the *Doe goe* of the Chinese, attains a length of two feet under favorable conditions, or about half that of its native growth. The white Turnip, while sweet and tender, is of smaller size than in China or in California. This is of lengthened form, with a weight of possibly fifteen pounds as an indigenous production.

The Chinese Spinach (*Boe choy*) grows much larger here than our common garden species. In full growth its clear white stem is about the ordinary size of the Celery-stalk. It is tender and succulent, growing in the rich soil of its new location. The *Fon qua*, or Pumpkin, of this introduction, is of lengthened form, resembling a club. The *Foo low goe* may be easily identified from familiarity with any other varieties of the Gourd. A more peculiar variety of its species is found in the *Boe qua*, or crescent-shaped white Cucumber. Two kinds of Citrons are produced in diminutive size compared with the growth of the species in China or in Cuba, where the largest specimens of the fruit may weigh fifty pounds or upward. On Long Island the average weight is about two pounds. One variety, with furry exterior like the caterpillar, is known as the *Don qua*. This is largely used in soup, while the *Zit qua* is preserved in the form of sweetmeats. The Lettuce is produced in some quantity as *Shang choy*; Celery as *Hon kon*, and *Yuen si* is Parsley of a high flavor, and corresponding value.

All vegetables are sold in the Mott Street market-places by weight. The exhibition of these is made in baskets, and with single specimens hung by strings outside the doors of Chinese groceries. The production is managed with great care and diligence, the methods being those of China, with only such natural modifications as may be indicated in connection with a fresher soil and with implements of improved varieties in some part adopted.

New York,

E. T. Lander.

New or Little Known Plants.

Acidanthera bicolor.

THIS plant, which is figured upon page 486 of this issue, belongs to the Iris family, and although the flowers are not as brilliant in color as those of some of the species and varieties of the nearly allied *Gladiolus*, it is an interesting and valuable addition to the list of bulbs which serve to make the flower-garden attractive during the summer. The bulb is small, not exceeding an inch in diameter, with *Gladiolus*-like foliage and a lax flower-spike two or three feet in height. The flowers, which are deliciously fragrant, especially in the evening, are long tubed and somewhat pendulous, with a creamy white perianth, marked with broad, chocolate-brown blotches. This plant requires the treatment given to the tender species of *Gladiolus*, except it is found to prefer a somewhat stiffer soil. It can be propagated by seed or by the small bulblets which it produces in great numbers.

The illustration upon page 487 represents a number of these plants grown together in a tub, which bloomed during the month of October in a garden near Boston. It serves to show the value of this plant, and several others of the same class, for the decoration of conservatories or living rooms, after the frost has destroyed the beauty of out-door gardens.

The flowering time of nearly all these plants can be retarded by starting them late, and, in this way, they can be got to flower, with the protection of a frame or cold pit, considerably later than their usual period, and at a season when flowers are not abundant.

The genus *Acidanthera* was established by Hochstetter, and the plants which are included in it are distinguished

by their pointed anthers, as the name implies. Ten or twelve species, natives of central or southern Africa, are now referred to this genus. *A. bicolor** was first collected by Shimper in Abyssinia and was described as long ago as 1844, although it has never been very well known in gardens, and no figure has been published of it, with the exception of the early and not very accessible one quoted below.

W. E. Endicott.

Dorchester, Mass.

Foreign Correspondence.

London Letter.

ALTHOUGH the past season has been considered unfavorable to Chrysanthemums, yet the quality of the flowers has, so far, been very satisfactory. The Japanese kinds were exceptionally good at the exhibition of the National Chrysanthemum Society, held this week in the Aquarium at Westminster; indeed, all the cut blooms were considered fine. But we have too many names for these plants, and the proposal that has been made to reform this matter by holding a special exhibition for the purpose next November, comes none too soon. Next year will be the centenary of the introduction of large-flowered Chrysanthemums into Europe, and it is proposed to celebrate it by an exhibition of an exceptional kind. This would afford a good opportunity for dealing with the name difficulty. Roughly, we have about a thousand names for Chrysanthemums, and new ones are added by the dozen annually. You in America are held responsible for a good deal of double naming, more especially among the Japanese kinds, for you import new kinds direct from Japan. These you give your own names to. We get them, too, from Japan, and name them, and afterwards find that some of ours are identical with yours. However, a few new ones have lately been raised in England that are good and well marked. Such is *Stanstead Surprise*, with very large flowers, the petals of good substance, curled and colored rich crimson, fading to pink, the under-side being silvery; *Alpha*, *Album Fimbriatum*, *William Holmes* and *Mrs. J. Wright* are others. But the flower of this year is *Edwin Molyneux*, of which some gigantic blooms were shown at the Aquarium, and were greatly admired by the crowds. Probably the desire for big flowers is a little absurd. They are certainly lacking in beauty when seen on the plants, and on the exhibition table they are misleading. After all, the right place for a flower is on the plant which bore it, and the best Chrysanthemum is that which makes the prettiest picture as a whole.

The most striking of the newer Orchids flowering now is *Cattleya Bouringiana*. This plant is certain to become as popular for winter flowering as its near ally, *C. Skinneri*, is for spring. These two species resemble each other very closely; in fact, much more so than many others which are recognized only as varieties. Still they are distinct enough in their seasons of flowering, and *C. Bouringiana* has the advantage in that it blooms when Orchid flowers are scarce. It requires the same treatment as *C. Skinneri*, and is one of the freest of all *Cattleyas* in respect of growth and flowers. The latter are rose-purple; the lip, which is funnel-shaped, being maroon-purple with a white blotch in the throat. *Cypripedium Elliottianum* is the latest of Mr. Sanders' grand list of new introductions. This enterprising nurseryman has done more to enrich Orchid collections than any other importer of recent years. Within a very short time he has introduced *C. Sanderianum*, *C. Rothschildianum* and *C. Elliottianum*, a magnificent trio, certainly. The last is named in compliment to Mr. Elliott, of your city. It has the habit of *C. Stonei*, and very large handsome flowers on scapes about a foot high. The dorsal sepal is one and one-half inches wide and two

* *Acidanthera bicolor*, Hochst. in *Regensb. Flora*, 1844, 25—Bouche & Wittm. in *Berlin. Monat.*, xix., 12 t., 1. Baker in *Jour. Linn. Soc.*, xvi., 160.
Ixia Qartiniiana, A. Rich. *Fl. Abyss.*, ii., 310.
Sphaerospora gigantea, Klatt in *Linnaea*, xxxiv., 699.

and one-fourth inches long, white, lined with crimson; the petals are white, blotched and lined with crimson, narrowed towards the apex and about six inches long; the pouch is like that of *C. Stonei*, ivory white, veined and tinted with rose. A thousand plants of this new introduction will be sold by auction on the 16th inst. *Phajus callosus* is a recent addition to the Kew collection, and is now in flower. It has the habit of *P. grandifolius*, but the flowers have yellowish-brown sepals and petals, and a funnel-shaped white labellum, which changes to cream-yellow with age. This species, together with *P. Wallichii*, *P. bicolor* and *P. grandifolius*, should be in every collection of tropical Orchids, as they grow and flower very freely under ordinary treatment. Such kinds as *P. tuberosus* are too expensive to procure, too difficult to grow, and too prone to die suddenly for most Orchid growers, albeit they are exceedingly beautiful when in flower. We have a *Cypripedium mania* in England—indeed, one might safely say in Europe—and there are evidences of its having spread to America, for a single plant of *C. Marshallianum* was lately purchased at an auction here for an American collection, the price paid being 150 guineas. In my opinion this plant has little to recommend it save its hybrid origin, and its being a little less beautiful than one of its parents, *C. concolor*, and a little more attractive than the other parent, *C. venustum*. Hybrids which are ugly to look upon, which none save those affected with the mania would waste a second glance upon, realize ridiculously high prices. The consequence is that every grower of *Cypripediums* has begun to cross them, and hopes for something new. In a few years we shall have as many named *Cypripediums* as we now have of *Chrysanthemums*, for it appears that every hybrid is dubbed with a new name.

In an article on the culture of *Phalænopsis* which lately appeared in GARDEN AND FOREST, it was stated that *P. Lowii* was apt to lose its leaves in winter, and that it required a light position. This pretty species is grown very well at Kew, last year producing branching spikes nearly three feet long, with over thirty flowers on each. The treatment there for it is as follows: House, a hot, moist, rather shaded one, with the plant suspended near the glass. It is fastened on a teak raft with a good layer of living sphagnum about the roots. During summer it is watered daily; in winter the moss is kept green. The leaves remain on the plant all the year round, and strong spikes of bloom are produced annually.

Mr. Cannell, of Swanley, has introduced and raised many very useful flowering plants, but it is questionable if he has ever made such a lucky-hit as with his new *Begonia Octavie*, of which he had a magnificent group at the Aquarium show. The flowers are exactly like good blooms of *Gardenia Fortunei*, quite as white, as full, and of as good substance. The plants are scarcely a foot high, freely branched, and the racemes are erect and many flowered. It is only by examining the leaves that one is assured of the correctness of the name *Begonia* for this plant. Flowering in November, it becomes doubly valuable.

These new *Begonias*, which the Messrs. Veitch have obtained by crossing the distinct winter-flowering *B. Socotrana* with some of the tuberous-rooted kinds, are unlike other *Begonias* in several important particulars. The most valuable is that of holding their flowers for several weeks, which if cut and placed in water will last at least three weeks. I have proved this with flowers of *B. Socotrana*, as well as of its progeny. The best of the latter is John Heal, which has rosy-crimson flowers. Winter Gem is another good variety, and I hear there are several new ones of the same race which are described as considerable improvements on those named.

Ipomæa Horsfalliæ, *I. ternata* and *I. Briggsii* are three first-class, stove, winter-flowering climbers. The first is an old favorite, its large axillary bunches of brilliant rose-crimson flowers being admirable in every way. The second is sometimes known as *I. Thomsoniana* or "the

white *Horsfalliæ*," and was introduced a year or two ago. It resembles the first named in habit, but the leaves are thicker in texture, and have three instead of five divisions; the flowers are large and pure white. *I. Briggsii* is a variety of *I. Horsfalliæ*, and is characterized by its smaller flowers, which are deep rose-colored. These three species are now bearing hundreds of flowers in the stoves at Kew.

Cacti are not popular in English gardens. *Opuntia Rafinesquii* is grown by a few, but most of these plants are practically unknown here. Probably you have in America other kinds than the *Opuntia* mentioned, which would be hardy in England. Information on these would be specially interesting to English readers of GARDEN AND FOREST.

November 9th.

Summer Apples in New England.

THE planting of Apple trees must have been begun in the very earliest years of the settlements at Plymouth and Boston, if we are to believe the statements, taken from old records, of the large quantity of cider made before these settlements were ten years old. Doubtless most of these trees, if not all, were grown from seeds brought from their old homes by the settlers. Grafting was but little known or practiced, and even up to the beginning of this century, and in many parts of the country considerably later, seedling orchards, in which only here and there were trees producing fruit of edible quality, were the rule.

It was, doubtless, a good thing in the end that such a great number of seedling trees was allowed to grow and bear fruit, since among these have been found nearly every popular and profitable Apple now grown in this country. Foreign varieties have never gained any great foothold in New England, and, with the exception of Russian Apples, valued especially for their hardiness against the severe cold of northern New England winters, they are not likely to do so, because very few of them equal our own best sorts in all that makes these fruits desirable.

Up to 1840 commercial orchards, except for cider, were almost unknown, nearly every family, even in the cities, growing fruit enough on its own grounds for a home supply. It was the easy intercommunication between the residents of the larger places which first popularized and extended the cultivation of the best known sorts of fruit. In all villages were sons and daughters of farmers, who rapidly spread the knowledge of choice fruits to the homesteads from which they sprang, and, as the interest grew, small nurseries were established near the towns for the propagation of these selected Apples. In this way a lively spirit was awakened, and between 1835 and 1850 orcharding, as now understood, had a very rapid growth and development. During this time and afterwards, the springing up of the Washingtonian temperance movement led to the destruction of large numbers of the old cider-orchards, and, though some such still survive, most of the orchards in New England now mainly consist of grafted trees.

The Massachusetts Horticultural Society did a most useful work in disseminating a knowledge of good sorts of fruit, and although modern means of transportation were unknown, yet all through the settled region—in every village and hamlet—there were some persons who managed to secure, grow and extend the knowledge of the best varieties. During that time most of the Apples were selected which still constitute the standard list, both for commercial and home use.

The first summer Apple that became widely known was the Early Harvest, styled by Downing "the finest early Apple yet known." Before its advent the American Summer Pearmain was considered the best early Apple, though in Maine the English Sops of Wine, known there more generally as Bell's Early, was found to be more suited to the climate. Shortly afterwards the William's Favorite, which originated within the present limits of Boston, began to be known, and it now takes the lead as a choice market variety. Everywhere the Harvest was planted, but in very few places has it ever grown perfect fruit long. While the trees are young this Apple is often very fine, but in a few years the scabbing and cracking fungus gets a hold upon it which is rarely broken. For this reason the Harvest has never been much of a market Apple in New England. The Pearmain has almost passed out of cultivation, and is rarely seen upon the street-stands, which contain mostly the Red Astrachan. The

Fig. 75.—*Acidanthera bicolor*.—See page 484

Favorite requires high culture to bring out its merits, but so grown it takes the first place in the better class of fruit-stores, though inferior grades are freely sold on the street. The new Russian Apple, Yellow Transparent, is beginning to be seen, and, as it is so easily grown, and comes so soon to bearing, it is likely to rival the Favorite in popularity. These two Apples are about of one size and shape; the one a solid, rich red, and the other a clear, straw yellow. Among the summer sweet Apples the Sweet Bough stands first; but sweet dessert Apples are comparatively little in request, and not

common on the stands or in the shops. I give the name by which this Apple is commonly known, though Downing gives preference to Large Yellow Bough. I frequently hear it called still "Sweet Harvest," though not so often as when it was more often sold with the Early Harvest. As we go northward we find Sops of Wine and Red Astrachan—the first in Maine, and the other all through Vermont and New Hampshire, as well as Maine. In Vermont, especially in the Champlain Valley, the Summer Pippin (locally known as "Paper-skin," and elsewhere in the State as "Champlain") has great

popularity. This Apple is large, handsome and excellent in quality. In northern Vermont its season extends into September. Away from Lake Champlain it is not much cultivated, and is comparatively little known elsewhere in New England, being more especially a New York Apple. I think it nowhere grows so large and fair as on the Champlain shores and islands. Its New York synonyms are Haverstraw Pippin, Nyack Pippin, Geneva Pearmain and Walworth. In Massachusetts the Foundling occupies about the same season as the Summer Pippin, while the Duchess of Oldenburgh comes into market before August expires.

can be no doubt that some of our finest Apples, especially among the summer sorts, require high cultivation to be permanently productive and profitable. These trees produce as large fruit as later sorts, and in equal abundance. It is reasonable, therefore, that they should be well fed and cared for, and the fruit properly thinned. When these things are done the fruit is larger and fairer, and the trees maintain their vigor much longer. The profit, in all fruit-culture, comes from the largest and fairest fruit, and this is not gathered from neglected trees.

Newport, Vermont.

T. H. Hoskins.

Fig. 76.—*Acidanthera bicolor*, grown in a tub.

The Early Strawberry, Early Joe and Primate are seen as summer Apples quite frequently in New England, but mostly imported from states south and west. In Maine, two native Apples of merit—Cole's Quince and Moses Wood—may be classed as late summer, though mostly maturing and marketed after the first of September. In northern Maine, New Hampshire and Vermont the Yellow Transparent is the only Apple which ripens its entire crop before September.

The Summer Apples of Rhode Island and Connecticut include all of those in favor in the states north, with the addition of a number of sorts which would there be rated as "early fall."

In regard to what is known as the failure of varieties, there

Green-house Climbers for Cut-flowers.

Clerodendron Thompsonæ.—This handsome and showy plant, belonging to the scandent section of the Clerodendrons, is a particularly useful climber for cut-flower purposes, being most effective for basket-work or dinner-table decoration, where its bright crimson flowers, with their pure white calyxes and their naturally graceful habit of growth, produce a charming effect. It is of easy culture, but it produces better and more abundant flowers if it has a season of rest to properly ripen the wood. *C. Thompsonæ* does best when potted in light loam, to which is added a moderate quantity of dry cow or sheep manure, and an occasional watering with liquid manure

will also improve the growth. It should be grown in a warm, light house, with just shade enough to prevent the foliage from scorching, and it needs frequent syringing to keep down red spider. This treatment should be persevered in until August or September, or later if desirable, when the supply of water should be gradually decreased until the wood has ripened and the foliage dropped off. The period of rest should be from two to four months, after which it may be started into growth again, and will soon give an abundant crop of flowers. Probably the easiest method of propagation is by root-cuttings, made by cutting moderately strong roots into lengths of from one to two inches. These should be placed in pans of light soil, and the pans should be set in a cutting-frame or on a bench having some bottom-heat. Here the roots will soon start, just as some of the *Bouvardias*, *Aralias* and other plants do when similarly treated.

Stephanotis floribunda.—The handsome, dark green, glossy foliage, and pure white, fragrant flowers of this excellent plant are well known, and its free habit of growth makes it one of the most useful of white-flowered climbers. It will grow very well in an intermediate house, where the temperature ranges from fifty-five to sixty degrees, and, if space can be spared for it, it will grow more rapidly when planted out and the shoots trained on wires attached to the roof of the house, but if it is not convenient to grow it in this manner it may be put in a pot or tub and trained on a balloon trellis. The soil most suitable for it is composed of light loam and peat in about equal proportions, with a liberal allowance of sand and a little broken charcoal, and in mixing the soil it is better not to break it up very fine, as the plant does best in a rather coarse, open soil, and needs free drainage. The *Stephanotis* is readily propagated, either by cuttings or from seed, but some growers prefer cuttings, and on the ground that the plants so produced are more floriferous than seedlings. The cuttings should be made of moderately hard wood, and if given some bottom-heat they will emit roots in a few weeks.

Passiflora racemosa (*princeps*) is another beautiful climber, and when well-established it produces its bright red flowers all the year through. The long and graceful flowering sprays of this plant are specially adapted for draping around large flower-vases or for mantel-decorations; and used in this way they are very striking and effective. This plant is also of easy culture, its chief requirements being good drainage, a moderately light soil and a temperature of about sixty degrees.

Watering with liquid manure at intervals during the growing season is beneficial, and care should be taken to prevent the mealy-bug from gaining a foot-hold, as when this pest becomes established on plants of this class it is difficult to exterminate it. *Passiflora racemosa* may be increased by cuttings or by grafting, and in the latter case either one of the free-growing *Tacsonias* or one of the other *Passifloras* of rapid growth, such as *P. Raddiana* (*Kermesina*), may be used as a stock. Grafted plants usually make more rapid growth than those on their own roots, and therefore that plan for increasing them is generally adopted.

Philadelphia, Penn.

W.

Soils.

THE importance of special soils for the different genera or species of plants is often overrated, and the different formulas found in the cultural instructions of various catalogues and works on horticulture are often useless or misleading. These specific directions as to soils have frightened many persons from growing plants both in the open air and in window gardens. American writers are comparatively free from mistakes in this direction; but in nearly every foreign publication on this subject the peculiar soil in which each plant should be grown is carefully described, and too often the mixtures recommended can only be obtained at an expense that amounts to prohibition. It often happens, too, that the directions laid down with such care are ludicrously useless, for our climate at least. For instance, an English writer asserts, "To grow *Portulaca* well it should be given a soil composed of turfy loam, leaf-mould, well-rotted manure in equal parts, and a little silver sand added." For a plant that comes up so freely everywhere as to become a troublesome weed, this attention seems quite unnecessary.

The simple preparation of the soil according to rule would require a considerable amount of labor, even though the materials were at hand. Few persons would think of taking so much trouble for a choice and costly plant, much less for those that thrive in neglected places.

The fact is, that where common vegetables will grow, flowering plants will grow, and if the books say turfy loam, and you have a clayey soil, or a sandy loam, put in your seeds,

bulbs, plants or trees without fear. Hoe frequently and thoroughly, and good fruits and flowers will be the result. It is true that some soils are more productive than others, or are easier or more difficult to till; some require more manure than others; and yet any soil that will produce good Beans, Beets or Potatoes will produce flowers as well. And soil that is best for vegetables in the garden is best for plants in pots. Exhausted soil will not produce good garden crops. You can no more draw from the soil without making deposits than you can from your bank. If you overdraw in either case your drafts will be dishonored. And as the amount of soil in pots is of necessity limited, it should in all cases be made strong and rich. The best soil for this, or any other purpose, is well-rotted sod, and this can be procured anywhere. Take sods from the road-sides or meadow, pile them up in any convenient out-of-the-way place, and let them rot, and you will have all the elements that contribute to the growth of plants. The best time for this work is in early spring, when the turf is fresh and green; then the roots will die quicker than at any other time. It is by no means necessary for the roots of the grass to become thoroughly rotted; all that is required is to have them killed, as the growing plant will feed upon the old turf as fast as it is decomposed. Plants grown in this soil will be strong, healthy and floriferous. A more rapid growth will be induced if a liberal proportion, say one-fourth, of well-rotted manure is added, in which case more weeds and worms must be contended with, but all trouble will be repaid by the increase in quantity and quality of bloom. Young plants intended for summer blooming in the garden should be grown in soil without manure, if it is naturally rich and not too heavy. Plants grown in such a soil will be healthy, and when planted out in the garden, they will have strength to assimilate all the food prepared for them, and will make a far stronger and more rapid growth than if stimulated at the outset in a very rich soil. The most successful Rose-growers use nothing but rotted sod for young plants, and the almost universal satisfaction their young stock gives, is due to this fact alone. The largest plant-grower in this country, if not in the world, has but one soil for everything, but one compost heap, and that is rotted sod. No doubt good peat or leaf mould will benefit a stiff, clayey soil for many exotic plants, and certain plants indigenous to a given soil and locality will thrive better there than anywhere else; yet the soil in which any plant is found in its native state is not always necessary for its perfect development. Indeed, many plants will not succeed as well in a soil that is natural to them, when they are grown in a different country, where climatic influences are different; for instance, the Cactus, or, at least, most of the genus, is found growing in arid wastes, but, introduced into green-houses, they will not thrive in the soil brought from their native habitats. The different atmospheric surroundings make a different soil necessary. Earth and air must work in harmony together to produce the plant.

Again, it is true that all plants cannot be grown equally well in a clayey or in a sandy soil. But your soil will need no more manipulation for flowers than it does for vegetables. Work well the soil you have, give it food if exhausted, drain it thoroughly if wet, but do not be discouraged in planting bulbs, seeds or shrubs, because you have not some special soil recommended in the catalogues and trade journals.

Garden City, New York.

C. L. Allen.

Top-dressing for Trees.—Now is the time for top-dressing around evergreens and other choice trees and shrubs. First clear out dead grass and leaves from under the young Conifers, as they afford a favorite lodging-place for field mice, which are so destructive in winter in gnawing off the bark of trees. And in place of what is removed return a dressing of rotted manure under and around the trees. At Mr. G. W. Childs' place, near Philadelphia, I lately observed that a heavy dressing of manure, and sometimes of loam and manure, was being strewn under and around the trees, whose splendid vigor is ample testimony of their appreciation of this generous treatment.

Pruning Trees.—Now that the trees are leafless, we can readily see where branches cross and rub each other, where some project too far, where the trees are too thick or are lopsided, and we should prune accordingly. Avoid heavy pruning. Cut off clear all stem and root sprouts. And where it is necessary to cut off large branches, saw them off short, then smooth over the cut with a sharp knife or small plane, and paint the wound to exclude moisture and prevent rot. In some trees, Lindens particularly, we often find diseased branches; cut these quite out at once, for there is no cure for them. In other cases, branches of Yellow-wood, Willow

or Thorns are badly infested with bark-scale, and I have never found a sure, practical cure for this pest except by cutting out and burning the affected branches. This scale sometimes takes such full possession of Lilacs as to compel the sacrifice of the plants. In the case of Oaks, Beeches, Maples, and other large trees which no longer need pruning to regulate their growth, we can do little now, because the dead twigs and limbs cannot be readily distinguished among the leafless branches. Cutting these away should be attended to when the trees are in full leaf. Where it is necessary to remove trees in order to open vistas, or for other purposes, the trees should always be rooted out and not cut down; the stumps should never be left in the ground. Sometimes beautiful views across the country can be seen over the tops of a clump of trees. See to it that these trees are headed so low that they do not intercept the view in any way.

Pruning Shrubs.—In pruning shrubs we wish to preserve symmetry of form and promote vigor, and at the same time to secure a profusion of flowers. Shrubs that bloom in spring on the previous year's wood should not now be pruned, but rather after they have done blooming. These include Daphne, Forsythia, Bush Honeysuckle, Japan Quince, Red Bud, African Tamarisk, Corylopsis, Snowball and the early blooming shrubby Spiræas. But such shrubs as bloom on the current season's wood should be pruned now, and in some instances quite severely back. These include *Hydrangea paniculata*, *Lespedeza bicolor*, Althæas, Chinese Tamarix, Stuartias and the like. *Desmodium penduliflorum*, *Hydrangea radiata*, *H. arborescens* and *Callicarpa purpurea* seem to do best when cut down close to the ground every year.

Out-door Roses. Roses should not be pruned at this time of year except to cut in very long shoots. If pruning is deferred till spring, we can cut back into the living wood, where the tips have been winter-killed. Prairie Roses and other climbing varieties grow late in the fall, and these late-formed, sprawling growths should be cut away of tied up, for tidiness' sake. If *Rosa rugosa* has outgrown its bounds, dig around it deeply and remove all suckers; these make capital plants for a fresh plantation. Also save the seed hips and sow them now in boxes of sandy soil in a pit or green-house, or if you do not want them yourself, exchange them with some neighboring florist for something that you may need. Although this Rose reproduces itself freely from suckers and seed, it has never become very plentiful. Moderately tender Roses, that need a little protection in winter, can be bent down and covered with earth. But, usually, a good mulching of littersy manure over the roots, or, if the shoots are bent down, over them as well, will suffice. Evergreen branches laid over the bushes are also a good protection. Tea Roses are safer if lifted now and heeled into a frame or potted and plunged in a frame till spring. Hermosa, Mrs. Degraw and some other Bourbons get cut back to the snow line or near it every winter, but this does not seem to injure them, and, when pruned in closely, they throw up vigorous, free blooming shoots. W. F.

Glen Cove, New York.

The Forest.

Do Forests Influence Rainfall?

IF I could find the place on the earth of which it was first and emphatically said, "It never rains but it pours," I am convinced that it would be a plain largely deficient in forest-growth. For, if there be an influence upon moisture conditions of the atmosphere exerted by forest areas—and such areas must not only be of sufficient size, but also densely enough covered to exert their proper influence upon temperature and moisture within and without—it consists, I believe, in a more equal distribution of precipitation with reference to space and time.

In the end, what does it matter whether it is by increased precipitation that the forest benefits the field, or whether the same physiological effect is produced by increased relative humidity in other ways, or by raising the water level and increasing or advantageously disposing of the available water supplies through favorable ground-water conditions or surface channels?

As this question of forest influences is one which, to a great extent, underlies the demand for national interest in the forestry problem, it may be of advantage to review briefly the methods which have been employed to solve the question. Space will not here allow a critical consideration of the value of each method, which may be done at some future time.

As is natural, the first suggestion that a relation between climate and forest-areas exists, came from general observation.

History testifies that districts once surrounded by verdant groves, with fertile soil and favorable climate, have become inhospitable and desert wastes, with treeless mountain-sides, and the conclusion follows that there is some connection between the forests on one hand and fertility and genial climate on the other. This method of proving the proposition, which has been the most popular, and is still largely in vogue, may be called the historico-statistical. Among the eminent men who have used this method may be mentioned Du Monceau, Reaumur, Buffon, Humboldt, Arndt. It is not to be entirely discarded now, but its results must be adopted with caution, for not only are the reports of the facts in many cases dubious, but the inferences are not always reasonable.

About the middle of this century, with the development of physical, and especially meteorological science, a second method was applied. This method attempted, upon a theoretical basis, to discuss and reason out the assumed relation by employing the accumulated physical and meteorological data, which, scanty at first, has lately been considerably increased. Among the prominent meteorologists to employ this method first was Becquerel. The results of this method have brought us considerably forward in the determination of the direction in which an influence would be possible, or even probable; and while it has not been able to either prove or disprove satisfactorily the existence of this influence nor advanced our knowledge of its degree and quality, it has cleared the way for a more scientific consideration and investigation of the subject.

The next step and method of demonstration employed was the mathematical one, using numerical data which had either accumulated independently of the question or were specially provided for the purpose. We have here to distinguish two methods, a wholesale and a retail one, if I may so express it, or, more scientifically speaking, the one using large averages and comparing data from extensive areas, though not specially provided for this end; the other comparing data obtained for the purpose in limited localities by direct detail measurements within and without forest areas. The latter method, which I call the retail one, is the one now largely adopted by German investigators.

The first attempt to obtain, for the settlement of this question, a series of exact, methodical observations, dates back to the year 1864, when Dr. Ebermayer, Professor at the University of Munich, constructed the necessary apparatus, and with the aid of the Bavarian Government and Forest Administration established in 1866 the first three double stations, where a set of meteorological instruments were observed within a forest area, and another set simultaneously in a field. In the following year the number of the double stations was increased to six. In 1869 Switzerland followed with three stations; in 1870 Italy established a station, and in 1874 to 1877 Prussia entered upon this field of work, having now sixteen stations in connection with the forest experiment stations; and to-day quite a number of double stations are collecting data in all parts of the country.

The points of observation at the Prussian stations are chosen 200 metres (about 664.5 feet) distant from the edge of the forest within and without. An enormous amount of material has accumulated, but as yet has not been summarized or turned to account. It is difficult to see how anything else can be demonstrated by it than what is already known—namely, that the meteorological conditions within the forest are different from those prevailing without. Whether the forest conditions are communicated to the open field, and to what degree, if at all, can certainly not be proved by the data obtained. By establishing points of observation in the field at varying distances, it might have been possible to demonstrate the presence or absence of climatic interaction between forest and field.

In the wholesale methods, which use data obtained over large areas independently of the special objects of this investigation, we may again discern two ways of handling them: the one comparing the data found during various periods at the same stations and bringing them in relation with forest conditions existing at the various periods; the other comparing data obtained simultaneously from stations situated differently as regards other climatic influences. The first method has been employed by Mr. Gannet and Mr. Harrington. Mr. Gannet endeavors to establish by a combination of data that neither for Ohio, which has been largely cleared, nor for New England, which is said to have largely increased its forest area, nor for the Prairie States, which contain more timber in recent times than formerly, can a noticeable difference in rainfall be demonstrated. In fact, however, he only proves that his method leads to no certain result for lack of adequate data to work upon. Mr. Harrington's method fails to be con-

clusive for the same reason—lack of proper data. He arrives at the opposite result from that of Mr. Gannet for the same region by comparing the position of isohyetal lines constructed for two different periods about thirty years apart.

The second class of wholesale methods, which compares data simultaneously obtained from stations differently situated as regards forest conditions, has been lately employed by the eminent Russian climatologist, A. Woeikoff. He chooses an area in northern India, which is partly a treeless region and partly densely wooded, and is otherwise uniformly situated with reference to other climatic influences. He concludes from his data that, at least for sub-tropic regions, a forest cover has the effect of reducing temperature extremes and increasing precipitation.

Woeikoff further investigates whether the influence of the forest upon the climate of surrounding areas may also be proved for latitudes of thirty-eight to fifty-two degrees north—all the West European Continent—and he proceeds as follows:

Taking the temperature of July as that of the warmest month, and assuming that, on the whole, the temperature at the Atlantic coast is lower and rises toward the interior of the continent, he compares the temperature of a number of places situated near the fiftieth degree, the observations being all taken outside of the forest. To bring them upon a uniform basis for comparison, he assumes an increase of temperature of 0.5 degrees, centigrade, for each degree of latitude towards the south, and a decrease of 0.7 degrees for every hundred metres of altitude. By an easy calculation he then obtains the mean July temperatures for every station in this line, reduced to exactly fifty degrees, north latitude, and 200 metres of altitude.

The result is that in this series a rapid rise of temperature appears from the Main River, eastward, then a considerable reduction in the eastern and western Bohemian stations, where large forest areas prevail, while in the Bohemian basin the temperature is higher, as it is also in Silesia, and again much lower in the well-wooded Carpathian Mountains of Hungary. The apparent influence of these large wooded areas is still noticeable in east Galicia as far as Kiew, where the neighborhood of forest and morasses works in the same direction, while in the Steppes the highest temperature is reached.

In the same manner a series of stations lying on or near the forty-sixth degree are treated, reducing their July temperatures to the theoretical temperatures for the forty-sixth degree and 200 metres of altitude; and another series of stations is worked out for the forty-fourth degree in Croatia, Bosnia, Herzegovina, Dalmatia, and here the heavily wooded Bosnia is found from twenty-five to forty-five degrees cooler.

The results of these comparisons lead the author to conclude that in the western part of the continent large forest areas influence the temperature of neighboring localities, and interrupt the normal increase of temperature from the Atlantic Ocean into the interior of the continent to such an extent that even regions far in the interior have a cooler summer than those nearer the sea.

He concludes further, not only that there exists a climatic influence of the forest, but that it exerts itself over considerable distances according to the size, kind and position of the forest areas; that, therefore, forest-planting or deforestation offers a means of changing a climate considerably.

Another modification of this method has been employed by H. F. Blanford, and by Dr. Brandis, late Forest Inspector-General of British India, by comparing the records over a confined area (61,000 square miles and 600,000 acres, respectively) during a decade of forest destruction and a decade of forest protection under government regulations. In both cases a progressive increase of rainfall is observed in the second period, until the mean increase within ten years has been twenty per cent. and twelve and one-half per cent., respectively, for the two areas thus reforested.

The latest interesting, instructive and quite novel application of the wholesale method is that employed by Dr. F. J. Studnička, Professor of Mathematics at the University of Prague. It consists in comparing the rain records of stations differently situated as regards forest conditions, after the records have been reduced to a theoretical quantity which corresponds to the altitude of the station. To understand the significance of these observations, the reader should refer to a map of Bohemia, and note its peculiar geographical position, being a basin shut in on all sides by high mountain ranges, inclosing an area of about 20,000 square miles.

This basin has been covered with a net of over 700 rain-gauge stations, for the purpose of obtaining accurate data of the quantity and distribution of precipitation over the king-

dom. Uniform ombrometers (rain gauges) were used and very carefully placed. As at present organized, there is one station for every thirty square miles. No other country, I believe, can boast of such a service. Although the time of observation at most stations has been short, and the averages would have been more accurately represented by an extension of observations for ten to twelve years, yet the last four years of observation, for which all stations furnish data, according to the author, represent two extreme and two average years, and are therefore quite useful.

The very large mass of material permitted a sifting out of doubtful observations without impairing the number available for the construction of a rain-map of Bohemia, showing by isohyetal lines seven rain belts or zones, the lowest belt showing an annual rainfall of less than twenty inches, the second a rainfall of less than twenty-four inches, the third of twenty-eight inches, and so on.

Sufficient material was on hand from which to calculate the influence of altitude on the increase of precipitation, although for altitudes above 1,600 feet the material is not considered reliable. Yet the general law is well shown that with the altitude the quantities of precipitation increase in a retarded progression. This progression is calculated by forming zones for every hundred metres of altitude, grouping the stations in each, calculating the mean elevation and also the mean precipitation as observed for each; then by dividing the difference of precipitation in the neighboring two zones by the difference of altitude, the amount of precipitation which corresponds to each one metre of elevation within that zone is found. With this figure the average amount of rainfall which, theoretically, belongs to each station, according to its absolute elevation, can be approximated by adding to or subtracting from the mean precipitations of the zone the proper correction for the number of metres between the actual altitude of the station and the mean altitude of the zone.

And now comes the application of this method to the question in hand. The author argues that if the actually observed differs considerably from the theoretically calculated rainfall, this is an indication that special influences are at work. He finds now that of the 186 stations which he subjects to scrutiny (these offering the longest and most trustworthy observation), forty-eight show a considerable excess of the observed over the theoretically expected rainfall, and he finds also that these stations are situated in the most densely wooded portions of the kingdom. The increased rainfall on the forty-eight stations is so considerable, that enough of it may be credited to other local causes, as, for instance, to the height and form of a mountain range on one side or the other, and still leave a large balance to be accounted for. Besides, the greater amounts of rainfall at these stations have been used in calculating the averages for the altitude zones, magnifying, therefore, these averages, so that the difference between the calculated rainfall and the actually observed rainfall appears smaller than it really is.

Expressed in percentages of the amount of precipitation a large increase is shown for several localities—as much as fifty-nine per cent.—and it would seem that so great an increase would not lose its significance as bearing upon the main proposition, even after every reduction for other influences is made.

Especially important appears the comparison between two stations near the rain minimum, for the influence of the forest is here plainly shown.

Correspondence.

Latinized Names of Garden Plants.

To the Editor of GARDEN AND FOREST:

Sir.—I take the liberty of applying to you as an acknowledged authority on botanical nomenclature, for information. I find that there is in the formation of a certain class of botanical names a great diversity of practice existing among the various writers for horticultural papers and those who prepare catalogues of plants. Is there any reason why I should write *Ainsworthii*, *Warnerii*, *Forstermannii*, *Nilsonii*, *Parishii*, *Roebellenii*, *Sallierii*, *Schlimerii*, and at the same time write *Regnieri*, *Barteti*, *Boxalli*, *Sedeni*, doubling the final -i in the one case and not in the other?

Linden, of Brussels, in his *Lindenia* uses the single i in all such instances. Sometimes in the same catalogue I find the same name formed at one time with a single -i and at another with the double. If you can give in your valuable paper any rule for the formation of these words you will greatly oblige

Yours very truly,

James R. Pitcher.

Short Hills, N. J.

[This question cannot be answered more clearly than by quoting the following extract from the Code of Nomenclature adopted by the American Ornithologists' Union, and as applicable to botanical as to zoological names :

"In Latinizing proper names, the simplest rule appears to be to use the termination *-us*, genitive *-i*, when the name ends with a consonant ; . . . and *-ius*, gen. *-ii*, when it ends with a vowel, as *Latreille*, *Latreillii*, etc. Since proper names for species, however, are used mainly—and we recommend that they be so used exclusively—in the possessive case, a still simpler and now generally adopted rule is to add an *i* to the name ; as *Latreille*, *Latreillei* ; *Hale*, *Halei* ; *Baird*, *Bairdi* ; but euphony may in some instances require the fuller form, and here, as in many other instances, is the case where an author has the opportunity of displaying his good taste."

The habit of Latinizing the names of garden varieties of plants—whether the result of natural variation or of artificial hybridization—is to be deplored. A much more simple and appropriate method is to use an English substantive to designate such plants, whether it be the name of the individual who originated or made known the variety, or otherwise. The general adoption of such a system of naming garden plants would simplify enormously the confusion which now exists in the nomenclature of garden botany.—Ed.]

Recent Publications.

A Provisional Host-Index of the Fungi of the United States. By W. G. Farlow and A. B. Seymour. Part I. *Polypetalæ*. Cambridge. August, 1888. Privately printed.

American mycologists and all students of American Fungi will find much needed assistance in this catalogue, which its authors have prepared and printed in the belief "that an approximately complete list of our parasitic species and their hosts would aid materially in the advance toward a more accurate study of our mycological flora, and would tend to lessen the amount of indiscriminate species-making which has already become a serious evil"—a result certainly most devoutly to be prayed for by all botanists. The host plants are grouped by families according to the system adopted in the "*Genera Plantarum*" of Hooker and Bentham, genera and species being arranged alphabetically in each family and each species being followed by a list of the parasitic Fungi found upon it.

Diagnoses Plantarum novarum Asiaticum, by C. J. Maximowicz, extracted from the Bulletin of the Imperial Academy of Sciences of St. Petersburg. The seventh part of this work, which is invaluable to all students of the botany of the countries of eastern Asia, and more especially of Japan, has recently appeared. It contains descriptive and critical remarks upon several new or imperfectly known species, an enumeration of the species of *Illicium*, *Scorzonera*, *Androsace* and *Gratiola*. An account of the large and widely distributed genus *Pedicularis*, into which are admitted nearly 250 species, occupies a very considerable part of the present issue, and is the most complete and comprehensive which has yet appeared.

A Synopsis of the Medical Botany of the United States, by J. W. Carter, St. Louis, 1888.

This is a list of the plants of North America which enter more or less regularly into the American Pharmacopœia. There are, the author tells us in his preface, 1,300 species and varieties of such plants, divided among 140 natural families and 620 genera. The list of these plants is published without characters or geographical distribution, and with the very briefest possible allusion to their medicinal properties, and it contains apparently no information not found in recent editions of the standard American Dispensatories, although the compact grouping of the species under the different genera will be found, perhaps, an aid to ready reference.

Recent Plant Portraits.

Botanical Magazine, November.

PHAJUS WALLICHII, *t.* 7023; one of the stateliest and largest flowered of all Orchids, widely distributed in the tropical portions of southern India, and not rare in cultivation. The flowers vary from chocolate-brown to pale primrose color.

PLUMUS FRAGRANS, *t.* 7024; a small Chilean tree of little ornamental value, but remarkable for the delicious fragrance of its foliage and wood. It is valued in Chili for charcoal making, the wood being considered superior for that purpose to that of any native tree. The dried leaves and twigs are occasionally used medicinally as a stimulant. The bark is used in tanning and the aromatic fruit is edible. *Plumus* belongs to the small order, *Monimiaceæ*, the plants of which are found in tropical America and Asia, Australia and tropical Africa.

IRIS KOROLKOWI, *t.* 7025; both the type and a bright lilac-purple flowered variety (var. *concolor*) of this very handsome Turkestan Iris are figured.

CALANTHE STRIATA, *t.* 7026; a native of Japan. The sepals and petals are cinnamon-brown with golden edges, internally, golden yellow on the outer surface.

AGAVE ELEMETIANA, *t.* 7025; forming, with *A. attenuata*, a peculiar section of the genus, with broad, entire soft leaves. It is a native of Mexico and has been in cultivation for nearly a quarter of a century.

ÆSCULUS TURBINATA, *Revue Horticole*, November 1st, Figs. 120-124; M. André here figures and describes the fruit of this interesting Japanese plant from the specimen in the *Arboretum Segrezianum*, which is believed to have been the first plant in Europe to produce fruit. *Æ. turbinata*, as it appears at Segrez, is a small, low stemmed, round headed tree, of compact habit, with leaves not unlike those of the common Horse-Chestnut. They are paler, however, on the lower surface, upon which the veins are more prominent. The fruit is sub-spherical, flattened on the upper surface, slightly or not at all turbinate, barely more than an inch in diameter, and produced three or four together in short, stout-stemmed racemes. The Horse-Chestnuts of eastern Asia, of which three are described, are still very imperfectly known.

DIOSPYROS VIRGINIANA, *Gardeners' Chronicle*, November 3d; a portrait of the old and very fine specimen growing in the Royal Gardens at Kew, and believed to have been presented to George III. by Archibald, Duke of Argyle, "the tree-monger." In another illustration a piece of the bark of the Persimmon is represented in a most admirable and satisfactory manner.

Meetings of Societies.

Pennsylvania Forestry Association.

THE annual meeting of the Pennsylvania Forestry Association was held in Philadelphia on Tuesday evening, November 27th. The report of the Council of the Association was a full and interesting review of the work of the Association and of the efforts for the advancement of forestry throughout the country. Among the facts set forth were these: The membership has increased to 450. Twenty-five counties are represented. The new members have been interested and liberal. With a view to employing a competent agent to deliver lectures on Forestry throughout the state, it was decided to raise a fund of \$5,000, and sixteen members have contributed \$440. Some progress was reported in the movement to convert certain small open spaces of Philadelphia into city parks. Encouraging interest has been manifested in the Michaux course of lectures, delivered by Professor Rothrock on "Trees from Florida to Maine." It is proposed to publish these, with illustrations, in *Forest Leaves*, the journal of the Association. There was increased observance of the spring Arbor Day by the public schools in tree and vine planting; the autumn day was improved by in-door instruction.

The Treasurer reported \$1,181.60 as the amount received during the year. An address to the American Forestry Congress at Atlanta was adopted, and it was resolved that the Council be empowered to send a representative to the Congress. A paper on "Forest-Planting in Virginia," by Mr. Burnet Landreth, proved to be a practical and valuable record of an experience of eighteen years in tree-planting on a 5,000-acre tract in tide-water Virginia. It was decided to publish the address and give it wide circulation.

Governor Beaver entered the hall just as the exercises were closing, and expressed profound interest in the condition and preservation of the forest area of the state, and spoke of his appointment of a Commission to attend the National Congress at Atlanta.

The officers chosen for the year were: President, Burnet Landreth; Vice-Presidents, John Birkenbine, Thomas J. Edge and Jeremiah S. Hess; Secretary, Mrs. J. P. Lundy; Treasurer, Charles E. Pancoast; Council at large, Mrs. Brinton Coxe, John P. Lundy, D.D., and Thomas H. Montgomery.

Notes.

During the past summer, a box of Carnations, sent from Providence, Rhode Island, to England, arrived at its destination with the flowers still fresh and fragrant.

At the Rookery, near Bromley, Kent, there is a Chinese *Wistaria* trained around the outer wall of a vinery and another wall running parallel to it and inclosing a piece of ground in the shape of a parallelogram. The longest branches which make this circuit have grown to a distance of 400 feet.

Tomatoes were introduced into Europe early in the seventeenth century, but for a long period were grown merely as ornamental plants. Despite the attractive appearance of the fruit, it was extremely repugnant to those who attempted to eat it, and the fact is perpetuated in the botanical name, *Lycopersicum*, which means "Wolf's Peach." Indeed, in Germany and some other parts of Europe, it is only within very recent years that the Tomato has won general recognition as a palatable and wholesome article of food.

Rosa rugosa, and the allied species, *Rosa Kamtschatica*, are being strongly recommended just now in England for the formation of hedges. They grow in that country with surprising rapidity and vigor, and develop so thickly close to the ground, that a single row of seedlings soon forms an impenetrable barrier, while the showy fruit and the beautiful flowers, which continue to appear after the fruit has reddened, and the glowing autumn colors of the foliage render such a hedge attractive to the eye for a large part of the year.

M. André, in a recent issue of the *Revue Horticole*, calls attention to the value of *Begonia semperflorens gigantea*, a hybrid between *B. lucida* and *B. semperflorens*, and its varieties, *rosea* and *Kermisina*, for the winter decoration of living rooms and conservatories. The foliage of these plants is thick and lustrous, and the pink or red flowers borne in large clusters continue to appear in the greatest profusion during the entire winter. Few plants can be cultivated more easily or are better suited for the purpose for which M. André commends them.

Professor Atwater has been placed in charge of the new Bureau of Correspondence with the Agricultural Experiment Stations at Washington. Bulletins will be issued, setting forth the results of experiments in this country, and these will be distributed among the stations. Specialists in this country and in Europe will be engaged to compile articles on subjects about which information is needed for general distribution. Another function of the Bureau will be to furnish Congress with information when legislation on agricultural matters is contemplated.

The death is announced of Mr. William H. Crawford, one of the most noted amateur horticulturists of Great Britain. A very rich man and a bachelor, he was, we are told, "personally of an ascetic temperament, but unsparing of expense when a good cause—charity, plants, books or pictures—was concerned." He may almost be called the creator of the Botanic Gardens attached to the University at Cork, and his beautiful place, Lakelands, near that city, is widely noted for its splendid collection of rare trees and shrubs from all temperate countries.

Wolfia microscopica, a species of Water Lentil native to the lakes of India, is the tiniest of all known flowering plants. It has neither stem, roots nor leaves, but consists of a fan-shaped body prolonged below into a root-like bladder, which serves to keep it in an erect position. From this bladder others develop, and so rapidly, that although a single plant is hardly perceptible to the naked eye, its offspring may in a few days cover a surface of several square yards in extent. In spite of its exiguous proportions and simple structure, the plant bears true flowers, although likewise of the simplest kind, each consisting of a single stamen or a single pistil.

The *Marysville* (California) *Appeal* has been collecting opinions from fruit-canners and shippers as to the desirability of irrigation for fruit. A wide diversity of judgment appears, but the general sentiment seems to be that fruit from trees not irrigated will keep better and endure long distance transportation more safely. Fruit from irrigated orchards is larger, fairer, better colored; but, being more juicy, it goes to pieces more readily. Some persons who prefer non-irrigated fruit for shipping, believe that in the same regions irrigated fruit is best for canning, drying and local use. Whenever it is possible by cultivation and thinning to conserve enough ground moisture to perfect a crop, irrigation is not generally advised. When it is practiced, great judgment should be exercised. When trees are watered copiously up to the time

of the fruit harvest, it is said that quality and flavor may be sacrificed for size and color. Winter and spring irrigation is commended, and to have its best effect the land should be well fertilized.

The new law regulating the forests of Russia, with a view to their preservation, went into effect on the first of last January. The law applies to all Russia, including the Caucasus and Poland, but not to Finland, which has its own forest laws. The rights of property are not unnecessarily interfered with, but the new law provides for the control and management of the forests of individuals where the public welfare seems to demand it, and the cutting down of such forests is prohibited when it might endanger the best interests of the whole community. A commission is created in each province, with the Governor at its head, for the purpose of administering the law and protecting the rights of property-owners. As might have been expected in the case of a law of this character, its application has been beset by many difficulties growing out of the conflicts between agricultural and forest interests and the unwillingness of the people to submit to any control in the management of their property. The law, however, is considered successful, and its application may be expected to increase immensely the material prosperity of the Empire.

It is well known that a great majority of the insects most destructive to vegetation which now infest this country have been imported from foreign countries and naturalized here. The unusual destructiveness of these species is generally accounted for by the fact that their natural enemies are not imported with them, so that their reproductive powers have freer play here than they had where such natural checks occur. But in a recent number of *Insect Life*, Professor Riley adds, as an additional reason, that most of such species are introduced from Europe or the older civilizations where, on evolutionary grounds, it is natural to suppose that they are the very species which have become accustomed to the civilized conditions induced during so many centuries. In other words, the species which most abound and have most successfully accommodated themselves to such artificial conditions, have, in the geologically brief period of man's pre-eminence, acquired advantages over species which have not been submitted to such environment. The former, when brought into competition with the latter, under such conditions, rapidly outnumber them and get the upper hand.

Every one has been writing about Chrysanthemums of late, but no one more interestingly than "Listener," of the Boston *Evening Transcript*. The yellow *Neesima*, for instance, one of the season's novelties from Japan, he says, "is the Chrysanthemum of Chrysanthemums—the loveliest of all the tribe, as well as the most characteristic, the most typical. . . . Its fluffly gracefulness, its long, slender, slightly curved petals, each like the line of Fusi-yama's curve, are intensely Japanese. One wonders whether the Japanese formed their art on the basis of this flower, or whether the flower was developed into its present form by contact with the Japanese genius." This praise is not too high nor is the admiration expressed for the variety in color and form shown in every large exhibition of Chrysanthemums. "The most striking feature of the exhibition, taking it as a whole, is, to the amateur without professional knowledge of the Chrysanthemum, the delicacy of the prevailing colors. . . . What a marvelous effect of color, . . . and what a preponderance of delicate shades, especially in light yellows and delicious pinks. . . . The strange and unusual tints . . . in almost all the exhibits it would be impossible to dwell upon, they are so infinite. There were many who stopped to admire the Elihu Vedder sort of pink of a Chrysanthemum called the Monsieur Freeman, . . . and over on the other side of the hall there was a tiny flower, growing in myriads on a big bush, that copied the homely tint of the Red Clover, that has blossomed for a week under the summer sun. . . . One may stand aghast, in a general sort of way, at the infinite varieties of the Chrysanthemum, but he cannot get a better idea of the scope of the flower, so to speak, than by comparing a certain big Peony-red flower of the species, which must be at least six inches across, and which has great, coarse, outward curving petals and a vacant, brown-red expanse in the centre, . . . with a little yellow flower on a big bush which bore the name of La Vogue—a bad name, because there was not the slightest trace of modishness about the little flower. The big red flower was all gloom and severity in its aspect; the little yellow flower carried with it an air of positive gaiety. . . . Probably there were 200 of these smiling little blossoms on the bush and every one was a distinct inspiration to merriment."

The Artistic Aspects of Trees.—V.

THE knowledge we need to gain, if we are to utilize to the best advantage such opportunities for planting as present themselves to us, is not a mere knowledge of the various forms and colors and textures that we may find in trees—it is a knowledge of trees themselves. Each species, each variety, presents itself to us as a whole made up of three blended elements, and it is the whole as such with which we should strive to familiarize ourselves. We must learn, not which tints or shapes in the abstract harmonize with others, but which trees are, from the point of view of beauty, fitting to associate with others. We must learn how each one looks in all the stages of its growth, at various seasons of the year, and under differing conditions of light and shade, of nearness and remoteness. If a certain tree seems out of place, we must be able to say not merely why we think so, but what other tree might better have been chosen. And when a spot is to be planted, we must be able to picture to ourselves how it should be filled, not in vague harmonies of abstract hues and shapes, but in definite mental portraits of actual trees.

Too often a much lower degree of knowledge than this is thought all-sufficient. Too often it is supposed that when one can recognize the trees he most commonly meets and call them by name, he really knows them. But he does not unless he can see them, so to speak, when he does not see them—unless he can recall the elements which make up their individuality and appreciate vividly their special qualities. We all can recognize our friends when we meet them. But something more than such knowledge as this is needed by the painter when he wants to compose a picture of many figures or to draw a face which shall have a given expression; and something more by the connoisseur, if he is properly to estimate and thoroughly to enjoy the artist's work. And as the painter and the connoisseur study and assimilate all they see, so too should the landscape gardener, and, no less, the lover of nature, if he wants to understand and enjoy to the full all that is offered him either in the unassisted work of nature, or in that which nature and the landscape-gardener have produced in partnership.

To study art as a preparation for the study and appreciation of Nature may seem, at first thought, a reversal of the right order of things. But it is in reality a wise course. If an artist were never anything more than a mere recorder of natural facts, a mere reporter in prosaic speech of things actually seen in this spot or that, his results would still be of service, enlarging our field of observation by the addition of his field and preserving for constant examination effects which are transitory in nature. But a true artist is something much more than this. He has at his command the power to preserve general truth of effect, and yet accentuate certain special truths more forcibly than, to our eyes, Nature has presented them. This power of interpretation in one man's work makes this thing more plain than Nature made it; in another man's it makes another thing more plain, and in the combined work of all makes Nature, as a whole, more plain, more vivid, more impressive. No matter how carefully and patiently we may study Nature in herself, we do not appreciate her to the full until we know what the great artists of the world have seen in her—how her forms, her textures, her colors, have appeared to eyes, tastes and feelings which by birth are clearer and keener than those of the average man, and by incessant training have been developed to a still higher degree of power.

In the study of form especially familiarity with landscape painting is of infinite value. Colors are so transmuted on canvas, and their variability from hour to hour in Nature is so different from their permanence in a picture, that to know what they really mean in Nature we must study them there. But forms are less variable in themselves, and are transferred to canvas with less intermixture of human personalities; and in no way can taste be so readily cultivated with regard to them as by a study of good landscape painting. Here it is that the painter's poetic power comes to help us—the power of idealization—of seizing this or that idea of Nature and expressing it more perfectly than, in this warring world, she herself is often able to express it. Colors so beautiful as those we find every day in Nature we seldom see approached in paint; but forms more perfect than those we are apt to see alive we constantly see on canvas. This is true even of the pictures of to-day, when of all artistic qualities form is the least highly valued; and it is even truer of the pictures of elder generations. The great classic masters of landscape—Claude, for instance, and Poussin and Ruysdael—are most valuable to the student of form in Nature; and, fortunately, their works can be as profitably consulted from this point of view in engraved productions as in their actual presence. Of course, it is not as text-books that they can be consulted, but as stimulants, as cultivators of the taste, as teachers of the great lesson, what is meant by beautiful forms, by satisfactory association of textures, by strong or graceful contours, by effective or subtle contrasts of light and shadow, by variety in unity, by diversity in harmony, by breadth, simplicity, repose and charm. These things they teach—not just what or how to plant in any possible given case; but these things we must learn in advance of any planting if we are to make a work of art of the result.

It is stated in the New Hampshire papers that preparations have been made to cut 6,000,000 feet of Spruce lumber this winter from the forests which lie about the base and cover the lower slopes of Mount Washington, the most important and the most frequently visited of the New England mountains. Six million feet of lumber is not a very large amount. It might be cut, if proper care was taken in doing it, out of the White Mountain forests without inflicting upon them any serious injury, and without in any way impairing the value of the White Mountain region as a reservoir of moisture, or as an agreeable and health-giving summer-resort. But care never is taken, or only very rarely, in American wood-cutting operations, and it is a foregone conclusion that in this case it will be

followed by disastrous fires, which will render useless what is now of great value.

The great reservoir of New England lies in the forests which cover the White Mountains and the elevated regions which surround them. This is also one of the most valuable and most generally frequented summer sanitariums in the United States. Its forests make it valuable. When they are gone its value as a natural reservoir is destroyed, and its value, with its beauty, to summer visitors and summer travelers, will disappear. These forests are the property of individuals, and no one can deny their right to cut them off if they think it is for their advantage to do so. Opinions may differ whether it is for the advantage of forest-owners to manage forests in such a way that three-fourths of their property is allowed to go to hopeless waste; but there can be no doubt—no question, that it is for the interest of the public that the White Mountain forests should be perpetuated in all their beauty and usefulness. The best investment the State of New Hampshire can make would be to buy up all this forest-region and hold it perpetually as a forest-reservation. The money it would cost would come back many times over in abundant water supply, and in the yearly disbursements of thousands of visitors from beyond the borders of the state. The railroads, too, which carry White Mountain visitors, and the owners of the hotels who feed and keep them, might do worse than secure control of this whole region and manage it with the view of making it perpetually attractive, which would mean perpetual preservation of the forests.

Whether, however, this region is purchased by the State of New Hampshire, or by a corporation holding it as an investment to be managed with a view of drawing from it the largest possible returns consistent with stability, it is certain that unless one of these plans, or some other, looking to the permanent safety of the forests, can be adopted, this region and its usefulness will be ruined.

Monsieur Buser, the custodian of the Candolean herbarium, has just published a supplementary volume to Bossier's "*Flora Orientalis*," containing the results of the latest investigations made upon the plants of the vast region covered by the work of the famous Swiss botanist, who died in 1885. A most interesting and appreciative notice of Bossier's life and of his contributions to science, from the pen of his compatriot, Dr. H. Christ, precedes the strictly botanical portion of the volume, which is further enriched by a portrait of Bossier. There are views, too, of the bust of Bossier erected in the Botanic Garden in Geneva by his sister, the Countess Agénor de Gasparin, and of the building containing his herbarium, one of the largest and most valuable in Europe, now the property of the city of Geneva.

The name of Bossier, one of the most distinguished of the group of systematic botanists who have produced Floras of great natural regions, will not soon disappear from the annals of horticulture. It was Bossier who discovered, during his first Spanish journey—afterwards described in one of the most delightful books of botanical travel—upon the summit of the Sierra Bermiga, near Estepena, the beautiful Spanish Fir (*Abies Pinsapo*), which he introduced into cultivation the same year; and among humbler plants for which our gardens are indebted to his zeal it is only necessary to mention the lovely *Chionodoxa Lucilæ*, which he discovered among the melting snows on the alpine summits of the western Tmolus, above Bozdagh, in Asia Minor, and which he dedicated to his wife, the companion of some of his early journeys. Bossier was a most successful cultivator of alpine plants, and his rock-garden, which he established as early as 1852, at his country place of Valeyres, at the foot of the Jura, must have been one of the most interesting ever made. The journeys of his later years (and the number was astonishing, in view of the vast amount of literary and herbarium work which he accomplished) were undertaken for the purpose of securing rare plants for his garden for which

he laid under contribution all collectors and all countries, and the plants others could not find, he went in search of himself. Here were mingled plants from the Rocky Mountains to the Himalayas, including those from every mountain chain of southern Europe and of the Orient, which no one has ever known, botanically, so well as Bossier. He cultivated, too, a large collection of exotic Orchids at his winter-home on the shores of the lake, near Geneva.

An appropriation of \$100,000, to enable the United States Geological Survey to begin an investigation into the practicability of inaugurating a national system of irrigation, by which it is hoped that immense tracts of lands in the Western States and Territories, now barren and worthless, can be made available for agriculture, was included in the Sundry Civil Appropriation Bill passed at the last session of Congress. Major Powell has estimated that the territory which can be reclaimed for agriculture by irrigation is equal in extent to the whole area now cultivated in the United States. It is impossible to determine, of course, whether his estimate is correct or not, but it is safe to say, with all due allowances for over-confidence in the possibilities of irrigation, as applied in western North America, that this new enterprise of the government is one of the most important, if not the most important, it has ever undertaken, and that eventually the national wealth must be increased by it enormously. Homes will be created for millions of industrious and prosperous families, and the natural products of the country will be increased enormously, it is safe to say. This appropriation, to which not a dozen members of Congress, probably, ever devoted a moment's consideration, seems destined to mark a new era in the prosperity of the nation.

The Pines in Mid-November.

THE foliage has mostly disappeared from deciduous trees and shrubs, but many herbaceous plants are wonderfully preserved. They escaped the light frosts of October, and the unusual warmth of November has endowed them with fresh vigor, so that in chosen spots among the Pines we still find many beautiful flowers. Some of the Asters, and even Goldenrods, are blooming still. But one of the most delightful surprises is a bed of blue Violets—a form of *Viola cucullata*. Not even in the spring-time have I ever found plants blooming more profusely than these. The flowers are large and bright blue, and, together with their leaves, make charming bouquets. But the most attractive novelty is a little patch of the violet Wood Sorrel (*Oxalis violacea*) in full bloom. It is under an old Pine tree; and standing well up above the dry needles which carpet the ground are a good many pretty flower-scapes, with several bright blossoms on each, but not a leaf has made its appearance. I shall keep watch of the future behavior of these plants. Next spring they will show probably nothing but leaves.

Another handsome flower is the Soapwort Gentian (*Gentiana Saponaria*), with half-closed corollas, but bright and beautiful with its smooth, deep green leaves, some of them inclining to a purplish tint. And near by is its small relative, *Bartonia tenella*, still in bloom. This little plant has small, inconspicuous white flowers, but in the middle of November the most insignificant flower that braves the weather commands our admiration for its sturdy character. I also find fair specimens of *Polygala lutea* in flower, and a species of *Xyris*.

The foliage that still clings to many trees and shrubs, which seem half inclined to be evergreen, is an interesting study. The leaves of the Swamp Magnolias, especially the younger ones, are as bright and shining as in midsummer, and those of the smooth Alder (*Alnus serrulata*) and Sweet Fern are still abundant, fresh and green. The leaves of the Wax Myrtle (*Myrica cerifera*) are now deliciously fragrant, and show no signs of loosening their hold. Indeed, like the Sweet Fern in sheltered spots, the shrub is nearly or quite evergreen, and holds its foliage well into spring.

In all my pleasant autumn rambles I have found nothing more beautiful than the running Swamp Blackberry (*Rubus hispidus*). Its delicate tracery of stem and leaf are laid over a bed of damp green moss. The foliage is charmingly colored in crimson, scarlet and purple.

The slender stems or long runners are quite free from prickles, and wind around among beautiful clumps of the Pitcher-plant, which are also gorgeously colored with crimson and purple veins. The bright cups of the Pitcher-plant are so flower-like, that they lure many insects into their depths, from which there is no escape. Two or three species of Lycopodium wind in and out among the moss, now hidden entirely from sight and again reappearing to throw up fertile spikes from a few inches to more than a foot in height. Standing a little in the background is the narrow-leaved Cat-tail (*Typha angustifolia*), which adds a special grace to the whole picture. This species is more rare and delicate than the common Cat-tail (*T. latifolia*), which grows in stagnant ponds and swamps throughout the United States. There is as much difference between these two Cat-tail flags as between the large Blue flag (*Iris versicolor*) and the slender Blue flag (*I. Virginica*), both of which grow near by.

The Groundsel-tree (*Baccharis halimifolia*) is now conspicuous with its long, white, silky pappus. Although it belongs to the largest order of flowering plants, it is the only one in this vast order, in our temperate climates, that attains the dignity of treehood. In the Pines it grows from ten to fifteen feet in height, and in autumn is a very marked feature in the landscape. The copious pure white pappus with which the fertile plants are enshrouded, at a little distance look like a mass of white flowers, strangely out of season in their rich setting of autumn foliage.

Two or three species of Dodder are now brought into view as the leaves of their supporters have withered or fallen. *Cuscuta glomerata* is the most notable, as its knotted cords strangle and sap the life of its foster plants until they are dwarfed, prematurely fade, and finally die. This species usually attacks the Composite, and sometimes other herbaceous plants. It starts from the ground like any respectable plant, and for awhile is self-supporting, and is quite attractive in appearance, with its bright orange stems. But it soon attaches itself close to some other herb, gives up its hold upon the earth, and relies entirely upon its host for support. Another species (*C. tenuiflora*) attaches itself to the shrubs among the Pines. This species has the appearance of twining more loosely than the former, and climbs higher on its foster plant.

Attractive plants are still found in the more exposed places on dry sandy soil. Among them is the smaller Pinweed (*Lechea minor*), a pretty little Heath-like plant growing in masses, but each plant is worth examining by itself, as its small single stem spreads out into numerous branches, giving it the appearance of a miniature tree. The branches and foliage form a dense mass a foot or more across the top, and the foliage has now taken on a purplish hue, making it very pretty and effective. These little tree-like plants are less than a foot in height, and grow in the most unpromising soil.

Hudsonia tomentosa is another little bushy Heath-like shrub about a foot in height, and covered with small persistent grayish leaves, giving the plant a hoary look. This, too, grows in the sand, even when it is so loose as to drift before the wind. Very often considerable patches of the plant are covered up in this way, and remain so until the wind from another direction blows the sand away.

Vineland, N. J., November 17th.

Mary Treat.

The source of the superiority of good landscape gardening lies in the artist's removing from the scene of his operations whatever is hostile to its effect or unsuited to its character; and, by adding only such circumstances as accord with the general expression of the scene, awakening emotions more full, more simple and more harmonious.—*Uvedale Price, 1796.*

To range the shrubs and small trees so that they may mutually set off the beauties and conceal the blemishes of each other; to aim at no effects which depend on nicety for their effects, and which the soil, the exposure, or the season of the day may destroy; to attend more to the groups than to the individuals; and to consider the whole as a plantation, not as a collection of plants, are the best general rules which can be given concerning them.—*Thomas Whately, 1770.*

It cannot be too strongly insisted upon that Nature is to be followed, not spoiled at the expense of labor and ill-employed wealth, not strangely and violently disfigured in the effort to embellish. All gardens cannot be planned after some one pleasing model. The special character of the ground must be regarded. By attending to this we shall be more faithful to Nature, and a greater number of gardens will be beautiful without being servile copies.—*W. S. Gilpin, 1832.*

Foreign Correspondence.

London Letter.

POTATO disease has been exceptionally virulent in England this year. Few kinds have escaped, many have suffered very severely, while in some districts the crop has been almost totally destroyed. We are no nearer a disease-proof Potato than we ever were, and as the wild tubers are said to be affected by it, there seems little hope in that direction. But the simple plan recommended by Professor Jensen, of Copenhagen, which is nothing more than high earthing in autumn, appears likely to prove a palliative at least. This has been shown recently by some experiments made at Chiswick, and which have been watched and reported upon by Dr. M. T. Masters. In August a portion of a plot of the variety Schoolmaster was high moulded, and another portion treated in the ordinary way. They were lifted on September 29th and carefully examined, the result being, that of those moulded in the ordinary way twenty-six per cent. were diseased, and that only ten per cent. of those moulded high, in accordance with what is known as the Jensenian treatment, were affected.

Orchids in November are either asleep or preparing for their spring display. Of course, there are Cypripediums and a few odds and ends besides, but, at this time of year, Orchid-houses are dull. Of new kinds, we have two forms of the richly colored *Cattleya aurea*, which are named *C. Massaiana* and *C. chrysotoxa*. The former is a supposed natural hybrid, *C. Gigas* being the other parent. The sepals and petals are rosy-lilac, the lips being large, crimson, with golden reticulations and two eye-like blotches of yellow. *C. chrysotoxa* is a very robust and large-flowered form of *C. aurea*, with the colors clear and rich in tint. Both kinds are Sander's introductions. *Lalia Perrini*, var. *alba*, is a form with flowers wholly snow-white, without any purple or yellow markings on the labellum. The leaves of the variety are larger and broader than in the type. It was introduced by Mr. Sander, and is now in the famous collection of Mr. R. H. Measures, Streatham.

The fortnightly meeting of the Royal Horticultural Society, held on the 14th instant, was devoted almost entirely to talk about the affairs and future of the society. Very few plants were exhibited, and of these only the following were noteworthy: (1) Malayan Rhododendrons.—The extraordinary success attained by the Messrs. Veitch in hybridizing and cross-breeding among plants of all kinds is very well attested by the marked improvement made in the habit, colors and variety of this section of Rhododendron. From two or three comparatively poor flowered species, obtained from Java and the Malay regions, at least a score of beautiful hybrids have been raised by the famous Chelsea firm, and all in the course of half a dozen years. Flowers of a dozen of the best sorts were sent to the meeting last Tuesday, amongst them being white, pink, crimson, nankeen, canary and salmon colors. These plants are easily grown, they flower freely, and the blooms last a month or more. (2) *Lalia Victoria*, a hybrid raised by the Messrs. Veitch from *L. crispa* and *L. Dominiana*. It resembles the former in most points, differing chiefly in the form and color of the labellum, which is oblong and spreading in front, undulated, and colored rich maroon-purple. I have seen forms of *Crispa* almost as good. It obtained a first-class certificate. (3) Chrysanthemums Mrs. Garner and Avalanche, which were certificated. They are both Japanese, the former very full, five inches across, rather flat, the petals narrow, and colored deep yellow, tinged with bronze; the other is also large, globose, very broad in petal, and of the purest white. They were from Mr. G. Stevens, of Putney. (4) Flowers of *Nymphæas* sent from Kew, where these plants are well represented and successfully grown. Those shown were all forms of the gigantic *N. Lotus*, the best of them being the seedling named *Kewensis*. The new tuber, *Stachys tuberifera*, was also certificated. At present it has little to recommend it, but it may be developed into a useful vegetable. The potato had not much to recommend it when it first came to England.

Kew has the following plants of interest in flower: (1) *Kennedy Marryatta*.—If your readers are not acquainted with this plant, permit me to recommend it strongly as a first-rate green-house climber. Planted in a bed of rich loamy soil, it grows very rapidly, soon covering a large space with its long, graceful branches. For training over pillars and rafters it is invaluable. The younger branches are pendent, a yard or more long, the leaves trifoliate, each leaflet ovate and two inches long, and the whole plant is covered with soft, silky hairs. The flowers are in short axillary corymbs, on stalks an inch long, each bearing four flowers, something like Sweet

Peas, and of the brightest scarlet color. Like all the Kenne-dyas, it is Australian. The Kew plant has been known to flower profusely for at least six months at a stretch. (2) *Hibbertia dentata*, which is another green-house climber of great attraction. It has oblong leaves about three inches in length and colored deep chocolate; the flowers are large, single and golden yellow. During winter this plant makes a pretty display. (3) *Senecio Ghiesbreghtii*, which is used here sometimes for out-door bedding in summer, but it is of greater value as a flowering plant for large conservatories in winter. The stem is stout and from six to ten feet high, with large ovate leaves a foot long, and enormous terminal corymbs of deep yellow flowers. It is planted in the beds in the Kew conservatories, and is in grand condition now. No doubt you cultivate this plant in your gardens, as it is Mexican, but it may not be utilized with you as a winter-flowering subject. (4) *Dahlia imperialis*, which is another giant composite from Mexico. In the gardens bordering the Mediterranean it attains magnificent dimensions, and at Kew it grows to a great size. The largest plants are twelve feet high, with a stout single stem, clothed with very large decomposed leaves, those at the base of the stem being about a yard through. The flowers are in large spreading panicles, very numerous on well-grown plants, and each one is six inches across, somewhat cupped, the single row of petals broad at the base and gradually narrowed to a long point; they are white, with a faint tinge of purple, the small cluster of disc-florets being yellow. As this plant blooms in November and December, it is valuable for the decoration of large houses. At Kew it is started early in spring in a little warmth, and then placed outside when the weather is warm enough. It requires a little heat in October and November to bring the flowers to perfection. (5) *Befaria glauca*, which is an interesting green-house shrub, introduced to Kew a year or two ago from the Andes of Peru. It flowered for the first time last year, and a plant of it is again in bloom. The habit is that of a Rhododendron, the leaves are about two inches long, glaucous beneath, and the flowers are in terminal spikes. The plant is only three feet high, with one stem, but this bears a cluster of seven erect spikes, each nine inches long, and bearing a score of flowers, which are bell-shaped, one inch across, and rose-colored. This plant is known here as the Andean Rhododendron. It is Ericaceous and evergreen.

Out-of-doors there is, of course, a scarcity of flowers, but we have three little attractions which deserve mention. They are: first, the autumn-flowering species of Crocus. The Kew collection of Croci is exceptionally rich, and they are arranged in two groups, the one autumn- and the other spring-flowering. Until only a year or so ago the autumn Croci were unknown in English horticulture here, but, thanks mainly to Kew, they are rapidly appearing in all good gardens. Of course, the display in the autumn depends very much on the nature of the weather, and in November it is seldom favorable to flowers. Lately, however, mildness, with a little sunshine now and then, have favored us, and consequently these Croci are good just now. Amongst them are white, lilac, mauve, purple, blue, and variegated. Altogether there are about thirty species of Crocus which flower between August and December, the first to appear being the pretty *C. Scharojani* of the brightest orange color. The cultural requirements of the species which bloom in autumn are exactly those of the better known spring-flowering kinds. The winter Daffodil (*Sternbergia lutea*) is another pretty and easily grown hardy plant which flowers at this time of year. At Kew it is planted in borders and bogs, where it never fails to develop its large, bright yellow, Crocus-like blooms. Close to it, or growing mingled with it, is the crimson-flowered Winter Gladiolus (*Schizostylis coccinea*), and the combination is pretty in effect. I suppose every one knows the value of the Schizostylis as a winter-flowering plant for the green-house, but is not often seen in a border out-of-doors. At Kew it remains in bloom till December, unless the frost is very severe, or there is a long spell of heavy fogs. Is *Hippophae rhamnoides* used as a garden plant in America? Here it is native, and consequently not often met with in gardens. It is the Sea-Buckthorn of every-day people. Planted on the edge of the lake, so that its roots are constantly under water, this shrub is a great success at Kew, every branch being now weighed down with the enormous crop of bright yellow berries. It is easily grown, and flowers and fruits freely every year. Being dioecious, however, one must be careful to get both sexes and plant them near each other, or no fruit will come. The berries have a strong styptic flavor similar to that of the Oleaster, to which the Sea-Buckthorn is closely related. *Crataegus Lelandi*, a form of the well-known Pyracantha, is a new addition to winter-berried hardy shrubs. It is useful as a pot plant, owing to

its habit of fruiting freely when only a few inches high. Large specimens are now a gorgeous picture of the brightest orange scarlet, the berries crowding on the branches much more than I have ever seen the old Pyracantha do. Whether grown against a wall or as a specimen shrub on a lawn, it is a perfect success. We are indebted to the Messrs. Veitch for its introduction.

W. Watson.

November 16th.

New or Little Known Plants.

Berberis Fremonti.*

THE Mahonia section of the genus *Berberis* is the exclusively prevalent one upon the western side of our continent, ranging from British Columbia to Central Mexico, and from the Pacific Ocean to the Rocky Mountains and the Gulf of Mexico, and is represented by half a dozen or more species within the limits of the United States. It presents also an exception to the general rule of resemblance of the eastern-Asiatic flora to our Atlantic-coast flora rather than to that of the Pacific, inasmuch as several species of this section are found in Japan, China and the north-eastern borders of India, and nowhere else in the Old World.

Mahonia differs from *Berberis* proper in the full development of all the leaves, and the consequent absence of spines (which in the common Barberry are abortive, primary leaves), and in the pinnation of the leaves, which consist of one or more pairs of leaflets upon a common petiole. This petiole is jointed at the base of each pair of leaflets. There are no differences of importance either in the flowers or fruit, and it is easily seen how the Barberry is simply a Mahonia with undeveloped foliage, the primary leaves being reduced to a cluster of spines, and the secondary pinnate leaves to the single terminal leaflet which is always jointed upon the very short petiole. The leaflets in Mahonia are always evergreen and spinosely dentate, usually rigid and glossy, and often strongly reticulate-veined. The berries are globular, or nearly so, and often blue or nearly black. The species most frequently met with in cultivation are the well-known "Oregon Grape," the *B. aquifolium* of the Pacific Coast, and *B. Japonica* from Japan. Several other species are doubtless as well worth cultivation.

Berberis Fremonti, the characters of which are well shown in Mr. Faxon's figure, is a shrub growing from five to fifteen feet high, found in the arid regions of the southwest from Texas to Arizona and Lower California. It is very peculiar in the character of its fruit, which at maturity becomes dry and inflated, inclosing six or eight seeds. What appears to be a form of this species, with comparatively broader, elliptical and less spiny leaves, occurs in central Texas, and was named by Mr. Buckley *B. Swaseyi*. Little is known respecting it.

S. W.

Pentstemon rotundifolius.

OF this plant, which was figured and described in the issue of this journal for November 28th, Mr. Pringle writes:

In the autumn of 1886 was found hanging quite in the manner of rock-brakes, from thinnest seams of dry granitic cliffs (on their sides least exposed to the sun), among the dry mountain chains southward from Chihuahua, a most singular Pentstemon, of so much beauty that Dr. Gray, when naming it as above, desired that efforts be made to bring it into cultivation. Seeds were accordingly distributed to botanic gardens, but in consideration of the strange habitat of the plant, it was with slight hopes of success. The plant is evergreen, with short stems which branch freely; its leaves are broad, very thick and leathery, glaucous; its flowers tubular, scarlet.

On its dry wall of rock, through winter frosts and the long term of fierce heats and absolute drought, when it

*B. FREMONTI, Torr., in Bot. Mex. Bound. Surv., 30.

would not seem possible for its roots to gather a particle of moisture, yet never dropping its leaves, this plant maintains an existence for many years, a remarkable example of adaptation to environment. When the rains begin, whether it be in March or not until August, it puts forth new branches and flowers, and continues to bloom while the atmosphere retains any considerable degree of humidity.

Nature's plan for disseminating and perpetuating the species amidst conditions so exceptional is also interesting. However pendant the stems, the dehiscent capsules are held upright by a bending of their pedicels; therefore a strong wind is required for the dislodgment of the seeds, a wind which will sweep them along the face of the cliffs, and haply plant one here and there in an open seam. It must be that all the seeds which fall upon the soil perish; for I have never seen a plant growing in soil about the dozen localities for this species repeatedly visited by me. Restricted in its habitat to so uncommon and austere conditions, the species is, as would be expected, extremely rare. I have not yet secured sufficient material to place it in my distributions of *Plante Mexicana*.

Cultural Department.

Mushrooms.

A NUMBER of market gardeners on Long Island have for some years been growing Mushrooms for market, and many others are now building cellars for this purpose. Mr. Abram Van Sicklin is the pioneer in this business, and perhaps the largest grower on the Island. Not only has he large and commodious cellars devoted to the cultivation of Mushrooms, but he also grows them in his salad-houses in beds under the benches on which the Lettuces are grown. In these houses the beds are now made, and extend the whole length of the houses, often a hundred feet or more, and under the middle and side benches. But as the night temperature of 40° to 45° required for Lettuces now (last week of November) is too low for Mushrooms (55° to 60°), the surface of the beds is covered over with salt hay. The heat of the manure in the beds is sufficient to spread the spawn, and the hay saves the surface of the beds from the chill of a low atmospheric temperature.

Mushrooms grow as well under a hay or straw covering as they do without it, but it is much more troublesome to gather them when covered. In Mr. Van Sicklin's cellar the beds are long and flat, arranged on the floor and on berth-like shelves above the floor-beds. He uses English brick-spawn, but has also used the French flake-spawn. He has made his own spawn, but, all things considered, believes it is cheaper and safer to use imported spawn, although the crop is uncertain at best.

Mr. Denton, of Aqueduct Station, is a successful grower of Mushrooms who has no greenhouses, but two large cellars. The one now being filled is some twenty-four feet square and about seven feet high, with a dry earthen floor. The beds are about four to five feet wide and arranged lengthwise on the floor, with narrow passages between them, and two shelf-like beds are fixed berth-fashion above each floor-bed, and at equal distances from one another. The bottom beds are floored and the shelves for beds are made and faced with rough hemlock boards. An iron stove and a line of sheet-iron smoke-pipe is used for heating the cellar.

The manure used is the ordinary stable manure from Brooklyn, which is hauled home on the return trips from market. This manure costs twenty-five cents a wagon-load in Brooklyn. After

a pile of it has accumulated the most strawy portions are shaken out and the rest thrown into a pile in a large shed to ferment. Here it is turned as often as necessary to prevent burning; after it is in active ferment it requires turning every day till the violent heat subsides, which may be in three weeks after the manure was brought into the shed. Mr. Denton has better success with his beds made up of loam and manure than when manure alone is used. Therefore, when the manure is in good condition he adds about one-third of its bulk of common field loam, mixing all well together before making the beds. The beds, especially the shelf-beds, can be made firm more easily when this loam mixture is used, the manure alone being too springy to pack well. The facings, or sides of the beds, are one board, or ten inches wide, and therefore the compost can hardly be more than eight inches deep at first, if space is left for coating it over with loam after spawning. Mr. Denton finds most danger in allowing the manure to become too warm after the beds are put up; at the same time he likes good lively manure to begin with. When the temperature falls to 90° he spawns the beds. He uses both French and English spawn, and buys the imported article. While the English spawn may yield the largest Mushrooms, he thinks that those produced from the French spawn are, in proportion to their size, heavier and

Fig. 77.—*Berberis Fremonti*.—See page 496.

more solid. In about six weeks after spawning he expects Mushrooms. A temperature of about 60° is maintained, but with an ordinary iron stove it is not an easy matter to keep up a steady temperature. And the stove heat, too, is apt to dry the earth on the surface of the beds, in which case they are freely sprinkled with water, but enough is not given to soak through to the manure.

While generally successful, Mr. Denton's crop varies a good deal in different years. Two years ago from these two cellars he gathered 2,200 pounds of Mushrooms, while last year his crop from the same space was less than 1,700 pounds. He is inclined to give a good deal of credit for the heaviest yield to the freshness and sweetness of his cellar that season, as he had it thoroughly cleaned out and limewashed in autumn before he made up his beds.

The one thing about Mr. Denton's arrangement that seemed faulty was the parching stove. A hot-air apparatus seems out of place wherever plants of any sort are grown, be they Mushrooms, Roses or Orchids. Besides, here is a big iron stove occupying a space which might be devoted to part of another floor bed and two whole shelf beds. A base-burner, hot water boiler and two three-inch hot water pipes run around inside the cellar, would seem preferable. The pipes could be run close alongside one of the shelves and would not be in the way at all, and any danger of their overheating the edge of the bed by which they were running could be averted by having a temporary board set alongside of them, making the shelf two boards high instead of one. No deep stock hole is required for these little boilers; they can be run on the common level of the cellar, and could be set into a niche in the wall four by six feet square. Two hods of coal a day will heat 300 feet of three-inch pipe. Surely this is better than any stove, and the first expense is the only one, for such an apparatus is simple and durable. We heat our Mushroom houses with this kind of boiler and hot water pipes, and nothing could do the work more effectively.

Glen Cove, N. Y.

Wm. Falconer.

Fruits for Cold Climates.

IT must be set down as a rule that a fruit-tree should be of a variety that will endure all weathers in the place where it is planted. It must be hardy enough to stand the test winter; otherwise, just when the owner is looking for a first full crop, he may find only a dead tree.

Experience has proved that the fruit-trees of western Europe and their seedlings will not, as a rule, endure the winter climate of similar latitudes on the American Continent. All of Europe north of Rome is north of Boston. Boston is nearly the extreme north limit of the Peach, Plum, Quince and Apricot; and of the Apples and Pears of north-western Europe very few can be planted with profit more than 100 miles north of Boston. Seedlings from these do not, as a rule, show more resistance to cold than their parents. So seldom do they, that those of us who have had most experience at once suspect that such a seedling is an accidental cross with a hardier variety, like those of Russia and Siberia.

The Russian tree-fruits are undoubtedly of hybrid origin. Those of Poland and the Baltic provinces are much mixed and crossed with west European species. But, working eastward in the empire, less and less of this blood is found; and in the valley of the Volga and the Steppe region the influence of north Asia stock preponderates. It is from these trees that we get our most perfect "iron-clads" of all the tree-fruits.

Our north-eastern states and provinces require hardiness against cold alone; but in the Prairie States this is not enough. Intense summer heat and drought, and the fatal sap-blight, must also be encountered there; and trees for that region must thus be triply clad. The fruits of the Russian and Asiatic steppes furnish the best material to meet these contingencies.

As New England lies mostly on the latitudes of southern Europe, so Canada lies mostly on the latitudes of Russia and Siberia. Not only climate, but the length of seasons and of days, should be considered in estimating the value of fruit-trees. The winter Apples of Russia are many, but south of 45° they are only early winter or fall sorts. This lessens their value for our Northern States; but as they can be grown among our tender long-keepers, there is a fair probability that iron-clad crosses can be obtained that will prove long-keeping below latitude 45°.

Unquestionably many European trees are, in their seedlings, gradually adapting themselves to the American climate. The law of the survival of the fittest is all the time in operation, and interested parties are finding along the northern limits of our orchard region (and even within it) seedling varieties which show unusual resistance against cold. After trying

several hundred of the hardiest Apples of southern Maine, New Hampshire, Vermont and Massachusetts in vain, and after coming to believe that there were no iron-clads among Massachusetts Apples, it was accidentally discovered (at the Centennial, I believe) that an Apple which I had received from Canada as the Strawberry of Montreal, is really the Foundling, which originated in Groton, Massachusetts.

Now that an interest has been aroused by the partial successes already attained, hardy seedlings are being sought out and tested all along our northern borders and in Canada. Scott's Winter is one of the Apples thus obtained, and though not an Apple of high quality or large size, it is a reliable keeper and a useful fruit, not only in itself, but as a beacon of hope for the future.

As for the Pears and stone fruits, the future is pretty secure, not only from the improvement of our native species of the last, but in the importation of the highly satisfactory Russian, Siberian and north Chinese varieties. I see no reason to doubt that, by discoveries already made, the orchard region on this continent can be extended from two to three degrees of latitude northward. That this is a wonderful gain, as the result of scarcely two decades of effort, is manifest; and there is more to come, for the work is scarcely begun.

Newport, Vermont.

T. H. Hoskins.

Our Native Plums.

I HAVE made a specialty of Plums of the American and Chicasaw varieties for sixteen years, and since 1874 have never failed to have a crop of plums—even the unprecedented winters of '80 and '81, which killed the Peaches here, while buds were dormant, failed to kill the Wildgoose, Moreman, Miner, or Newman Plums. An ordinary crop is the exception; an enormous one the rule. This season on very light, sandy soil, my Wildgoose trees—twelve years planted—averaged six crates of thirty-two quarts each to the tree, which netted in Baltimore \$1.60 a crate—the price ruled lower than usual because of the immense peach crop. With such experience a little enthusiasm may be pardonable. As a point of profit, there can be no comparison between these plums and varieties of the European species. With the latter, unceasing watchfulness and warfare against insects, at a time when labor of all kinds is pressing upon fruit-growers, is the price of a crop, while with varieties of the Chicasaw or American species, one longs for a more industrious breed of curculios to help in thinning out the crop. Among the most profitable varieties with me may be named Lone Star, Mariana, Wildgoose, Indian Chief, Newman, Quaker, De Soto, Robinson, Rollingstone, Golden Beauty, Moreman, and Wayland—named in the order of ripening. The number of varieties has increased rapidly within the last five years; such only are named as have had sufficient trial on my grounds to establish their value. The trees of the American varieties are more upright and much less scraggy in growth and habit than are those of Chicasaw parentage. As a rule, success with this class of Plums is rendered much more certain by alternating varieties in planting, because the stigma and stamens mature at different times in the blossoms.

As yet there seems to be no limit to the variations in seedlings, the Wildgoose being the parent of most of the varieties now cultivated. Six or eight years before his death Charles Downing suggested to me the possibility of obtaining a free-stone Plum by crossing some of our native varieties with the Peach. Accordingly, I used the Wildgoose as the female and Troth's Early Peach the male parent in a trial to effect this end. The result was a real cross, so far as habit and appearance of the tree are concerned, but a genuine mule in point of reproductive powers; flower buds in abundance there have been, but they never expand. Since that I have approached a free-stone variety pretty closely by using pollen from the German Prune upon the Richland Plum.

In my long study of native Plums, I have never found any evidence that the Mariana is a cross between the Chicasaw and some cultivated Cherry; neither do the facts in my experience lead me to believe that this alleged origin will bear the light of investigation. One fact alone seems to invalidate this claim: Neither the Wildgoose Plum nor the common Cherry can be successfully grown from cuttings, while the Mariana strikes almost as readily as a Willow.

Denton, Maryland.

J. W. Kerr.

Orchid Notes.

Erises Rohannianum is a choice Orchid, and much superior to any other of the Suavissimum section of the genus, to which it belongs. It is one of the recent introductions of Sander's, and is still somewhat rare. The racemes are some two feet long and densely flowered. The flowers are white, tipped with purple, the side lobes of the lip being citron yellow,

and the spur spotted with purple. The value of the flowers is enhanced by their delicious fragrance. The plant is a robust grower, and is doing extremely well with us in a wood cylinder, where abundance of water can be given the roots without danger of rotting them.

Trichosma suavis deserves a place in every collection, if only for its remarkable fragrance. But the flowers are very pretty, too; creamy white, with the side lobes of the lip striped with crimson, and borne on terminal racemes. The slender terete stems are about one foot high, surmounted by two broadly lanceolate leaves. This species is a native of the Khasia hills, evidently in situation where it has abundance of water, for in cultivation it can hardly get too much if the pots are kept well drained. A mixture of sandy peat and moss is a good compost for it, and a cool house is most suitable.

Vanda Sandieriana is now in flower with us. It is a magnificent Orchid, by far the handsomest of this large genus, and fortunately is now becoming more plentiful. In habit it resembles both *V. cœrulea* and *V. suavis*. The flowers are

Autumn Flowers.—The United States should be the country par excellence for Michaelmas Daisies, but, perhaps, these pretty autumn flowers are not so much valued as in Europe. Among the numerous species and varieties of the old world, *Aster Ibericus* deserves all praise; it is a native of the Caucasus and very much resembles *A. Amellus*, but the flowers are much better in shape and outline, bright blue with a tinge of purple, all opening nearly at the same time, forming an even umbel of nearly a foot across; its height is about two feet and it flowers in September. *Colchicum speciosum*, var. *maximum*, is now very showy, its numerous, bright-purple flowers being fully five inches across. *C. autumnale albo pleno* is a gem among late-flowering bulbs; its perfectly double, well-shaped flowers appear in numbers and last at least three weeks. A clump of Snowdrops in full flower is an uncommon sight just now, yet *G. alanthus Olga Regina* has been blooming since the first of October, to be followed by *G. nivialis corcyrensis* during November and December.

Baden-Baden.

Max Leichtlin.

Fig. 78.—*Elæagnus longipes*.

borne on short, stout, axillary racemes, of a roundish outline and about four inches across. The color of the upper part is a delicate blush, while the lower is greenish-yellow streaked and suffused with crimson. The small concave lip is purplish-red. Being a native of the Philippine Isles, it requires strong heat, light and abundance of water during growth.

A close rival to the foregoing and belonging to the same section is *Vanda cœrulea*, an older kind and much more plentiful. In this plant the racemes are longer and more loosely flowered, bearing twelve to twenty flowers; in color, lavender or light blue. This is a very unusual color among Orchids, and were this plant more easily grown it would become very popular; but, unfortunately, its cultural requirements are not generally well understood, and only rarely is it seen in really good condition for any length of time. It comes from the higher regions of the Khasia hills, and therefore requires comparatively cool treatment. It should also have plenty of light, abundance of water during growth, and a very long rest without shriveling the leaves.

F. Goldring.

Plant Notes.

Elæagnus longipes.

MR. CHARLES WRIGHT, the botanist of the Wilkes expedition, detected this plant at Simoda in Japan more than thirty years ago, and its characters were first made known by Dr. Gray in his now famous and classical paper upon the Flora of Japan, read before the American Academy of Arts and Sciences in 1859.

Elæagnus longipes is a low shrub in cultivation, only a few feet in height, although it is said to become a small tree sometimes in Japan. The branches are unarmed or sometimes beset with spines, angular, and covered with small, rusty-brown scales. The leaves are somewhat coriaceous, oval-oblong, contracted into rather a blunt point, smooth and dark green above, and covered on the lower surface with a dense silvery white pubescence. The small

yellow flowers solitary, or more rarely two or three together, are borne on long slender peduncles. They are inconspicuous, but the fruit, which appears in our illustration upon page 499, is exceedingly ornamental. It ripens in July, and is oblong, half an inch or more long, bright red, and covered with minute white dots. This plant may well be grown for the beauty of its fruit alone, which, moreover, is juicy and edible, with a sharp, rather pungent, agreeable flavor. Both the size and the flavor can doubtless be improved by careful selection, and it is quite within the range of possibility that it may become a highly esteemed and popular dessert and culinary fruit. To some persons, even in its present state, the flavor is far preferable to that of the Currant or the Gooseberry. The plants are very productive, as our illustration shows, and they are easily raised and perfectly hardy. They possess, moreover, the merit of carrying their leaves bright and fresh well into winter.

The Forest.

Forest Planting in Virginia.

AT the recent annual meeting of the Pennsylvania Forestry Association, the President, Mr. Burnet Landreth, delivered an instructive address, from which we are permitted to make the following extracts. Other portions of the address will be published in subsequent issues of this journal:

In 1870 the senior member of my firm, who had been for a long life a collector and planter of trees for ornamental purposes, till he had established a noted collection, decided to plant a forest on a large area of old farm land in eastern Virginia, on the lower Chesapeake, where we held about 5,000 acres. The annual rainfall there is forty-nine inches; the relative humidity, both during summer and winter, seventy-three; the maximum temperature, 103°, the minimum, 1°, above zero. The wind in summer, south-west; in winter, from the north.

Of this tract, about two-thirds were in original and second growth Pine, with some hard wood interspersed. He decided to plant the open farm fields, and follow upon the stump-land, as the forest was cut off. Experience had made clear to us the wonderful reproductive capacity of the soil of tide-water Virginia, in reclothing itself with the natural Pine of that region—the Loblolly, or old Field Pine. Still we thought it might be profitable to establish forests of trees, both evergreen and deciduous, not common to that section, which would promise to be more profitable than the ordinary Virginia Pine. Among native deciduous trees found there were the Chestnut, Walnut, Ash, Oak and many others, not occurring, however, in forests of one variety, but always mixed. So we concluded to try the experiment of forest-planting which, if not profitable to us, might, at least, serve as a guide to others in that portion of Virginia. Accordingly, after preparation in 1870, in 1871 we planted 100 acres with the nuts of Black Walnut, depositing the nuts at one foot apart in open furrows drawn eight feet apart. We followed this by planting eight acres with Chestnuts.

The next year, 1872, we continued planting both seed and seedlings. Of seedlings, we set out 30,000 Black Locusts, 5,000 Southern Cypress and 5,000 European Larch. These we planted in solid blocks, four feet by four apart, intending that they should prune themselves.

In 1873 we planted four bushels of Locust seed, twelve of Chestnuts and one-eighth of a bushel of Larch seed.

In 1874 we put in 150 bushels of Black Walnuts, ten of Hickory Nuts (*Carya tomentosa*), twenty-two of Chestnuts, one of European Larch, ten of Catalpa (*C. bignonioides*), three of Poplar, three of Pecan, one of White Oak, and one-eighth of a bushel of Italian Sumac. Of seedlings, we set out 2,000 eastern Catalpas, 5,000 southern Catalpas, and 75,000 Black Locusts.

In 1877 we set out 10,000 Catalpas, 1,000 White Ash, 15,000 White Pine, 1,000 Douglas Fir (*Pseudotsuga Douglasii*).

In 1879 we set out 40,000 *Catalpa speciosa*, 1,000 *C. Kamferi*, 150,000 *C. bignonioides*, 10,000 *Ailanthus*, and 3,000 Douglas Spruce.

Since the last date, 1879, we have set out a large number of Catalpas and this winter shall have 100,000 seedlings to plant.

Now, the result of all this has been much disappointment, but not despair. We were first disappointed in the Black Locust plantations. The early groves had reached a height

of twelve feet, the later ones, of course, being smaller. In the larger tracts the trunks were stocky, straight and limbless, the upper branches all interlaced, forming a solid roof, so that the midday sun seldom reached the alleys between the trees. They gave promise of a fine Locust forest, just such as we had pictured, but hardly expected to realize. But one September the Locust-tree Borer descended in swarms upon our groves, laying millions of eggs, which produced myriads of grubs, and by the next midsummer, every tree was ruined. We cut them down and pulled out the roots with oxen, the expenses of removal being twenty-five dollars per acre.

Next, the European Larch gave out in the trunk, the main stem breaking off at about twelve feet in height. This tree had never promised well, however. It thrives best upon dry, rocky soils; ours was a sand, with clay subsoil.

The Southern Cypress next failed, except in wet bottoms. Of Hickory and Pecan, the nuts planted were, to a large extent, stolen by the squirrels, woodchucks and field mice, and those that did vegetate made such slow growth that we plowed them out and replanted the ground with Catalpa. The Tulip Poplar was not a success, as the rabbits and field mice during winter ate off from the tender seedling the sweet, juicy bark, and destroyed nearly every plant. The White Oak acorns were largely stolen by animals, which also ate the bark of the young seedlings as they did that of the Poplar. The Italian Sumac, planted for its leaves, still stands, but the percentage of tannic acid in its foliage is not greater than in the leaves of the wild Virginia Sumac; and therefore its cultivation offers little hope of profit.

In short, with us, Black Locusts, Deciduous Cypress, European Larch, Hickory, Pecan, Tulip Poplar, White Oak, Osage Orange, Wild Black Cherry, *Ailanthus*, White Ash, Mulberry, and some others, have all failed.

Our successes have been principally in determining which varieties were not profitable to plant; and in this respect we have prospered famously. Our other successes, such as they are, have been achieved with four trees—Catalpa, Black Walnut, White Pine and Douglas Spruce.

Of the Catalpa we have abandoned several tracts, and, after most serious ravages by stray cows, half wild pigs, rabbits, squirrels, mice and fire, have about 200,000 trees, ranging in height from two to twenty feet, according to the period of planting. They stand in rows six feet apart, many of the rows a quarter of a mile long, and promise to make, in time, fine forest studies, if not eaten up, for the Catalpa, too, has its insect enemies. Two years ago every tree was denuded of its leaves, within a period of a month, by the ravages of the Catalpa Sphinx (*Darenma catalpa*). These have gone, but they may come again and may stay. Still, this contingency of destruction by insects unavoidably attaches to the culture of any forest tree. Of the Catalpas there are two types cultivated for forest purposes, the eastern and the western, indicated botanically as *C. bignonioides* and *C. speciosa*, the latter being the most approved.

The tree is as hardy as a Chestnut, of quick growth, the trunk and limbs, by reason of its resistance to decay, being valuable as fence-posts, gate-posts and mud-sills. I have a piece of gate-post which stood in place 100 years, and it is in a perfect state of preservation.

The timber when sawed takes a fine polish, and is handsomely marked in its cellular structure. The Catalpa has been used in the West for railroad-ties, and possibly it makes serviceable ones; by some enthusiasts it has been extolled as superior to the White Oak, but that is folly. A first-class tie must have other merits than ability to resist decay from moisture. The catalpa tie is deficient in power to resist the hammering of the rail under passing trains, and it is deficient in that adhesive power upon railroad-spikes possessed by white oak or chestnut. In oak very careful tests have proven that as much as a pull of 4,000 pounds is required to draw out a spike driven five and a half inches. In catalpa the adhesive power is not one-half of 4,000 pounds.

The second deciduous tree which we have planted in large number is the Black Walnut. In tide-water Virginia it is found wild and of noble proportions. Our seedlings, however, have grown very slowly. For the first six or seven years they grow but a little more than four inches a year, and it is only when they become very deeply rooted that they appear to start off vigorously. The lowland soils, however, are not adapted to the development of the best Walnut timber, the wood produced there being too full of silix. It will not polish as smoothly as timber grown upon a soft prairie soil. It is stronger and better suited for

the legs and rounded portions of furniture, but, as a rule, does not furnish handsome paneling. Our Walnuts, of which we have 150,000 left, after as many have been destroyed and others abandoned, do not impress us as of much value, and for the present we shall plant no more.

Our attention was directed to the White Pine as flourishing upon our particular soil by a wild settlement of these trees in the midst of one of our Yellow Pine forests. Here we found a parent tree, ninety feet high, grown probably from a seed dropped by a bird of passage, possibly from far-off Maine. It has germinated, reached maturity and developed seed, which, falling around, has in turn germinated and developed seed-bearing trees, till now the growth of several generations of trees stand in concentric circles. This natural group clearly indicates that soil and climate were hospitable to the White Pine. The results of our own plantations, in addition to this example, make it quite evident that the White Pine can be grown successfully. The principal difficulty with plantations of this tree lies in securing a stand in the first instance, as a large percentage of the seedlings die.

The Douglas Fir I consider the best of the two evergreens. It grows as rapidly as the White Pine, and if it escapes the ills of forest life and reaches maturity, it will be more valuable. One of its merits is early maturity. Its long, tapering and light trunk particularly suits it for ship-spars, while the older trees reach vast proportions and form a trunk far surpassing the White Pine of Maine. This tree for Eastern plantations should be grown from Colorado seed, as the Oregon variety is not so hardy.

I would recommend that the White Pine and the Douglas Fir be planted in alternate rows, so that in case of destruction of either variety by insect depredations or soil influences, there may be a chance for the remaining variety to reach maturity. Indeed, all plantations should be mixed for the same reason, but they must be mixed judiciously.

After eighteen years of practical forest-planting on a small scale, I conclude that for the particular region of tide-water Virginia—and I think I may venture to say as well for tide-water Delaware, Maryland and North Carolina—there are only four trees to plant; I conclude, also, that it is very questionable if it be profitable in that region to plant at all, so long as the Loblolly Pine will spring up in every field just as soon as annual cultivation ceases. How the seeds get there I cannot tell, but they will spring up in the centre of a one-hundred-acre field simultaneously with their appearance upon its tree-fringed borders.

This Pine will start without plowing, and it will grow under the most adverse circumstances. It will take care of itself in spite of wild hogs and stray cattle. Fire is its worst enemy. In twenty years it will make twenty cords of brick-yard fuel, and for every year thereafter an additional cord or more, till at forty years it will cut fifty cords of first-class wood; the only expenses being the taxes, which altogether do not equal one-half of one per cent.

Correspondence.

Horticultural Exhibitions.

To the Editor of GARDEN AND FOREST :

Sir.—Whenever I attend horticultural exhibitions in different cities, the question comes to my mind: Are they managed properly? Do we use the material to the best advantage, not only from an educational, but from a financial point of view? I have before me a number of reports of horticultural societies. Turning to the lists of standing committees, I find the names of men who have made national reputations for themselves in the learned professions, in art, in science or in various branches of business. Turning to the list of exhibitors, I find many names equally famous. In both cases they are men of refined and cultivated tastes; men who have proved their ability by their success. Again, I turn to the treasurer's report, and, without going into details, it appears, as every one knows, that the exhibitions rarely prove financially successful.

What are the causes of this failure, and what are the remedies? There are plenty of standing committees. Possibly they have been standing too long. There are plenty of good pushing men on them who are successful in their own business. Why are they not successful here?

Is it because they are held back by some of the older members who cling to "the good, old methods"? If it is a lack of money, this, I believe, could be overcome by personal subscription, if the members could show the public any advanced ideas that would be beneficial. The wealthy gentle-

men always seem very glad to do their part in contributing their specimen plants.

Allow me to suggest :

1. That the entire hall in which an exhibition is to be held be treated to a thorough cleaning.

2. That it be profusely decorated with Laurel wreaths, Laurel branches, evergreen trees and other greenery, from the entrance to the dome. In most cases I believe enough enthusiasm could be aroused among the members to contribute to this in the shape of labor, material or money.

3. That the tables, benches and staging, in every instance, be covered either with paint, moss or evergreens, instead of with bare, broken, rough and age-stained boards.

4. That in front of these tables, instead of allowing the trestles and horses to show or attempting to hide them with paper, I would suggest using some kind of cloth with eyelet holes fastened with screw-eyes, which could be used a number of years.

5. That proper vases be obtained in which to show cut flowers, and that these should be always kept clean, and particularly so if transparent.

6. That exhibitors of Grapes be requested to hang all Grapes, and that the amount of "bloom" be a strong point in judging, while those that have been carefully polished should be barred.

7. That if vegetables are to form a part of the exhibition, none but remarkable specimens be admitted.

8. That if enough social influence could be brought to bear, the first night be devoted to "Society," with lady patronesses and a banquet and bouquets for the patronesses only. I have no doubt but that the tickets or invitations could be disposed of at five dollars apiece. The day following should be open to all at fifty cents apiece. Every part of the house would have to be opened to accommodate the crowd.

9. That if "Society" could not be induced to participate (which is hardly probable, as there are so many fashionable people connected with horticultural societies), a number of influential ladies be induced to interest themselves as a Ladies' Committee.

10. That a little money be expended upon the local papers, which are always very kind, even to inferior shows. Make the exhibitions worth illustrating, and they will give you hundreds of dollars' worth of advertising.

11. That two orchestras be engaged to give promenade concerts at fixed hours and music at frequent intervals. Sometimes barely enough money is realized to pay a single band. Have enough music to pay for itself.

12. That all plants be named properly with both botanical and common names. Mark the *Peristeria elata* the Holy Ghost or Dove Plant; *Nepenthes*, the Pitcher Plant; *Platyco-rium Hilli*, the Stag-horn Fern. A little description of these flowers would attract a great deal of attention. A child can see the resemblance, and it would interest all, while heretofore they have been passed by almost unnoticed.

13. That exhibitors of cut flowers should be required to have them renewed or freshened up from time to time, and that all watering of plants should be done early.

14. That few complimentary tickets should be given out.

15. That all exhibits, and especially those of cut flowers and designs, should be judged by "points." If one plan could be adopted all over the country, judges from other states would be preferable.

16. That premiums should be liberal, and awarded with the greatest care.

17. That if at any time during the exhibition the attendance is not too large, complimentary tickets be sent to different schools interested in botany, which would prove valuable from an educational standpoint.

18. That the managing editors of the city papers should be notified of the efforts that are being made to make this the grandest display of plants and flowers ever offered by this society; that the "society" people of the city are taking a more active part than formerly, and that it is expected to be one of the social events of the season. That a committee of well-informed men be appointed to receive all reporters, not only to repay them in a slight way for their kindness, but to aid them in their work, that a technically correct report may be given of the exhibition.

19. That for a Chrysanthemum show the decoration should be most elaborate. Japanese vases, rugs, screens and lanterns would be very appropriate.

Philadelphia.

H. H. Battles.

Pinus sylvestris.

To the Editor of GARDEN AND FOREST :

Sir.—There are several specimens of the Scotch Pine upon the college campus here, and in most instances they are making a good growth. During the three seasons before the present one the trees have borne cones in abundance. This was strikingly true for 1887, and this spring the trees were conspicuously loaded with the old cones. These same trees—and there are several of them close by—this spring produced an unusually large number of staminate blossoms, but an extended search failed to reveal any pistillate clusters. We have scores of Scotch Pine trees upon our ornamental grounds, and among them all only one has been found this season bearing cones of this year's growth, and upon that there were not over a dozen. The striking contrast between the thousands upon thousands of cones of last year, and the almost total absence of them this season, has led to this note, with the hope that some dendrologist may assign the cause. Is it a case of over-bearing in 1887 and recuperation this season?

Byron D. Halsted.

Agricultural College, Ames, Ia., November 15th, 1888.

Recent Publications.

Handbuch der Forstwissenschaft, in Verbindung mit A. Buhler, R. von Dombrowski, W. Exner, H. Fürst, u. s. w., herausgegeben von Tuisko Lorey. In dreien theilen, in 8vo.; 630, 614, 576, ss. Tübingen, 1888.

Dr. Lorey, the learned professor in the University of Tübingen, has completed his work upon Forestry, which appears under the title which we have reproduced above. It occupies three stout volumes, and is rather an encyclopedia of forest science than a mere manual, in which different departments are fully treated by different specialists, among whom are found the names of some of the most distinguished professors in the German and Austrian forest schools. With them have been associated several practical forest experts in the preparation of this work, in which will be found a presentation of the different branches of science applicable to the management of the forest and of the methods of silviculture adopted in the different countries of central Europe.

The first chapter, from the pen of Professor Weber, of Munich, is devoted to forest statistics; the distribution of forests in the different European countries, and an examination of the historical causes which have developed their actual present condition. To this Dr. Weber adds an exhaustive and most interesting account of the influence of the forest upon climates, the flow of rivers and the composition of soils.

The second chapter, by Dr. Lorey, is devoted to an examination of the question of instruction in forestry in the different countries of the world, including statistical information relating to schools of forestry and forest experimental stations, with the courses of study and the organization of all such establishments.

Professor Schwappach, of Tübingen, devotes the third chapter to a history of European forests and of European silviculture, covering the period from the earliest days of modern civilization to the present time.

The fourth chapter is a treatise upon geology, mineralogy and chemistry, as applied to silviculture, from the pen of Professor Ramann, of Eberswald.

The fifth chapter is devoted by Professor Luerssen to a forest flora, in which are described the ligneous plants native of Germany, together with such herbaceous plants as are met with in the forest and all the cryptogamic plants found growing upon trees in Germany, and often the cause of serious diseases among them.

Professor Lorey, in the sixth chapter, discusses exhaustively, methods of natural and artificial forest reproduction, to which is joined a study upon the creation of nurseries.

Fürst, Director of the Forest Institute of Aschaffenburg, treats in the seventh chapter those questions which relate to the injuries inflicted upon the forest by man and by the lesser animals, including insects, by parasitic vegetation, and by the fall of meteors. A second part of this same chapter is devoted by Förster, Chief Forester at Gmunden, to a discussion upon torrents and avalanches—that is to say, upon the art of mountain restoration as it is technically known.

Professor Exner, of Vienna, examines in an exhaustive manner in the eighth chapter the properties of different woods from a purely technical point of view—their color, grain, specific gravity, odor, density and elasticity. In the ninth chapter the head forester at Hildburghausen, Stötzer, discusses the uses to which different woods and barks are applied,

methods of sale for forest products, the seasoning of timber, and of the harvesting and preservation of seeds. The second part of this chapter, by Professor Bühler, of Zurich, is devoted to a description of various forest products used in agriculture—forage, the bedding for domestic animals and manures. Professor Schuberz, of Carlsruhe, treats of the transportation of forest products; while the chemical composition of wood, its artificial preservation and the manufacture of paper-pulp, charcoal, wood-acid and resin, form the subject of a fourth division of this chapter, from the pen of Professor Schwackhofer, of Vienna.

Hunting and fishing and fish-culture occupy the ninth chapter.

Professor Lehr, of Munich, discusses in the tenth chapter capital and the formulas which must be followed in determining the relation of capital invested in forest property to its returns, relations which must be known in order that the most advantageous methods of forest management in different cases may be adopted. This is followed in the next chapter by an explanation by Professor Guttenberg, of Vienna, of the theory and practice of the measurements of the contents of timber in a forest, with tables showing the increase of different trees, both as solitary individuals and in masses.

The theory of forest management is developed by the director of the Forest Academy at Tharand, Professor Judeich, in the twelfth and most interesting chapter of the whole work, in which is explained broadly and clearly the principles upon which modern scientific forestry is based.

Professor Schwappach explains, in the thirteenth chapter, the organizations for the maintenance, in Germany, of forests belonging to the State, the Communes, and to individuals, while in the fourteenth and final chapter, Professor Lehr treats of the forest from the point of view of national defence and public wealth.

We have described at length the contents of this remarkable work, which is certainly the most comprehensive in scope and the richest in information that has yet appeared concerning the forest in its complex relations to modern society. In it are displayed very fully the actual condition of advanced knowledge in regard to the forests of Europe; and it stands as a worthy monument of the learning, industry and perseverance of the German officers who have made forest science what it is. The student of forests and forestry will find in it unlimited sources of information, but it is as an encyclopædia and not as a manual, as its title would seem to indicate, that Professor Lorey's great work must be considered, and like all encyclopædias, it loses something in the absence of unity of treatment and expression—an inevitable failing when a book is written by several authors working independently. But the book upon forestry is yet to be written, in which a master mind, having gathered all the facts which science has been accumulating during the past two centuries, exposes them in one compact, logical and well-balanced treatise.

Periodical Literature.

Attractive descriptions, profusely illustrated, of the environs of Vienna, are published in the October and November numbers of *Westermann's Monatsheften*. Vienna has grown with great rapidity during the past two decades, and the greatest intelligence has been displayed in laying out and planting the new quarters, and utilizing the possibilities which they offered for securing variety as well as beauty to the result. No finer streets exist than the encircling boulevards, laid out along the line of the old fortifications of the town, which are collectively known as the "Ringstrasse;" and in some of the suburbs villa-architecture, with all that it implies in the way of horticultural embellishment, has been brought to a very high degree of perfection.

In the *Atlantic Monthly* for October is a pleasant, poetical little pastoral in prose by Sophia Kirk called "Pasture Herb and Meadow Swath"—one of those witnesses to the development of love for nature and of the literary gift, to which we have referred more than once already as noteworthy proofs in the progress of American culture. In the "Contributor's Club," in the same magazine, is a brief but suggestive paper which enforces the fact that the more one knows the world the more pleasure it gives—that, in fact, we do not really enjoy it because we do not really even see it until we have learned for what and how to look. It is hardly needful to remind our readers that Mr. Burroughs has often preached from this important text; but too many teachers cannot join their voices with his in the effort to persuade people that the

study of natural science is far from being a dry pursuit, deadening to the æsthetic feelings—that it is, instead, a pursuit which, rightly followed, will deepen those feelings by giving them more and finer nourishment.

In the same magazine for November is an article, called "A November Chronicle," by a well-known naturalist, Mr. Bradford Torrey, which should be read by every one who fancies that summer must be really over because the almanac says it is. Who would believe, except upon evidence as good as Mr. Torrey's, that in the course of a Massachusetts November of average inclemency, seventy-three species of wild plants, representing twenty-two orders, were found in bloom? The list is given in full and is as varied as it is interesting. The great family of the *Compositæ* is most prominent with several species of Asters and Golden-rods, with Dandelions, Yarrow, Tansy, Cone-flower, Everlastings, Burdock and a number of others. But the Pea family is also well represented; the Pale Corydalis and even the Deptford Pink appear, while the Witch Hazel brings a single shrub in among the humbler plants. The places where most of the finds were made are described for the benefit of others who may wish to conduct autumn exploring expeditions, and also the relative profusion in which the various species appeared, some being very common, and others, of course, only isolated belated examples. Naturally the sea-shore proved the best hunting-ground. The list might have been increased, Mr. Torrey adds, had it been made to include garden-flowers, like the Pansy and the Larkspur, which he saw by the road-sides. But it was only of the veritable wild-flowers that he took account.

In the *Gentleman's Magazine* for November is an exhaustive, instructive and very interesting article called "Quinine and its Romance," by Mr. Alexander H. Japp. The title is not badly chosen, for the history of the Cinchona tree, as the source of one of the world's most valuable medicines, has certainly been a strange one. The precious powder was first brought to Europe in 1639 by the Countess of Chinchon, wife of a viceroy of Peru. Her name is, of course, the origin of the botanical name by which the great genus is now known, while quinine is derived from the native Peruvian term *quina*, and "Jesuit's bark" was long a familiar appellation, for the reason that the drug was long procured through the hands of Jesuit missionaries. It was a full century after the drug was known before the tree itself was discovered by a European—by Jussieu, in 1739. And then all the specimens which Jussieu sent home having perished, it was another century before growing trees were seen on European soil. These were specimens of *Cinchona Calisaya* grown in the Jardin des Plantes, at Paris, from seeds sent home in 1846 by Dr. Weddell. Attempts to cultivate Cinchona trees were made in 1852, in the Botanical Garden of Calcutta, but were unsuccessful, and the Indian government therefore sent the well-known botanist, Clement Markham, to South America in 1860, to seek for seeds of the various species and learn how they might best be grown. The history of the wanderings of Markham and his companions is one of the most interesting chapters in the history of botanical explorations. The many species of Cinchona trees are confined to the tropical regions of the Andes range, between about nineteen degrees south latitude and ten degrees north latitude, where they grow on the mountain slopes and in wild ravines, and their discovery was attended with the greatest hardships and dangers. But it is impossible here to do more than indicate the contents of Mr. Japp's paper, which, besides much historical information, gives, also, an account of the methods now employed in India, in growing Cinchona trees, in gathering the crop of bark and in preparing it for market.

A recent number of *Petermann's Mitteilungen* contains an interesting account by Baron Eggers, the well known explorer of the botany of St. Thomas, of a journey into the interior of San Domingo, illustrated by a large map of the districts traversed, from Puerto Plata on the northern coast southward to Santiago and La Vegas, and thence over the mountain-range south-eastward to Pico de Valle and south-westward to Maydama. Although the first part of the journey was along the chief route of communication between the seaport and the interior, the roads are so bad as to be passable only for pack-horses even in the drier seasons, while in the rainy winter all communication is often suspended for weeks together.

The first Pines which he saw were at a height of 590 feet above the sea level, and on the crest of the El Puerto range, at a height of 1,700 feet, they formed a magnificent forest

almost unmixed with other trees. The species is the same as that which occurs in Cuba—*Pinus occidentalis*: it extends up the slopes of the Sierra del Cibao to the summit—about 7,750 feet. Its range in altitude is, therefore, unusually great, although it seems to reach its greatest development at a height of about 4,600 feet. It is more particular, however, in regard to soil than climate, flourishing only where coarse chalk and red loam mingle in the subsoil. When these conditions are changed, the Pine disappears and deciduous trees take its place. As the undergrowth consists only of sparse shrubs, low-growing Ferns and Grasses, progress in the high mountain districts was found less difficult than in most other unexplored tropical regions. The chief obstruction came from frightfully heavy and prolonged thunder storms. In Jarabacoa, a village of 800 inhabitants, the church and the houses are built of small planks of *Oreodoxa oleracea* and thatched with the leaves of the same Palm. The inhabitants are chiefly occupied with Tobacco culture. In this neighborhood Baron Eggers found the so-called Nogal-tree (*Juglans Jamaicensis*). Further south and up to about 3,100 feet elevation the Pine woods contained a thick growth of *Davillia aculeata*, while the Manacle Palm (*Euterpe*) looked strangely side by side with Pines, and Bromeliads, with brilliant red leaves, grew upon the stems of the Conifers. In high districts, where the *Oreodoxa* does not grow, the houses are built of *Euterpe* planks and thatched with grass, no attempt being made to use the excellent wood of the Pines. The summits near Pico del Valle are covered in greater part with grass growing in thick bushy clumps, scattered through which are numberless small stones and some large rocks. Here and there are low thickets formed of shrub-like *Compositæ*, *Ericacæ* and of *Garrya Foyeni*, while between the rocks grows a yellow-flowered species of *Scrophularicæ*, a half-creeping *Andromeda*, and a multitude of plants which recall northern climates, such as *Hieracium*, *Alchemilla*, *Galium*, *Chimaphila*, *Pteris*, and, along the brooks, *Ranunculacæ* and *Carex*. On the flints which are strewn about here and there, a small-leaved *Loranthus* with rosy flowers is conspicuous.

Few other botanical details are given in Baron Eggers' paper, which is rather a geographical than a botanical treatise. Nevertheless, it will interest all who care to learn about the general aspect and the local peculiarities of a little known country.

Recent Plant Portraits.

CÆSALPINIA JAPONICA, *Gardeners' Chronicle*, November 3d; a Japanese shrub, with yellow flowers, introduced by the Messrs. Veitch, and interesting as the only representative of a generally tropical genus, likely to be hardy in northern gardens.

ENKANTHUS HIMALAICUS, *Revue Horticole*, November 16th; a representative of a small genus of plants of the Heath family, closely allied to *Andromeda*, and peculiar to the Himalaya, southern China and Japan.

The figure is from a plant which is described as hardy in the neighborhood of Paris, and which had been received from Japan, two facts which suggest the Japanese *E. Japonicus*, rather than *E. Himalaicus*, which is found in the hot and humid valleys of the Sikkim Himalaya.

ANGRÆCUM SANDERIANUM, *Revue Horticole*, November 16th; one of the most graceful and attractive of the small-flowered species of this genus, and a native of Madagascar.

TOXICOPHLEA SPECTABILIS, *Revue Horticole*, November 16th; fruit.

VOCHYSIA GUATEMALENSIS, *Botanical Gazette*, xiii., t. 23.

PITCAIRNIA TUERCKHEIMEI, *Botanical Gazette*, xiii., t. 24.

CROCOSMA AUREA, var. MACULATA, *Gardeners' Chronicle*, November 17th; a variety of a well-known plant, with orange-colored flowers, the segments of the perianth marked with a purple-red spot, and declared "to be the finest form of the variable *Crococma aurea* that has yet appeared." "It grows to a height of three to four feet, and single stems cut with their graceful leaves and placed in water, for in-door decoration, open their buds for weeks in succession."

MAXILLARIA FUSCATA, *Gardeners' Chronicle*, November 17th.

EUCALYPTUS VIMINALIS, *Gardeners' Chronicle*, November 24th; from a specimen grown on the Island of Arran, which has grown from the seed to a height of thirty feet since 1872.

CALANDRINIA OPPOSITIFOLIA, *Gardeners' Chronicle*, November 24th; a native of the coast mountains of northern California.

PINUS PINEA, *Gardeners' Chronicle*, November 24th; a portrait of the old species of the well known Italian Stone or Parasol Pine of Italy in Kew Gardens.

Notes.

During the year which ended on April 1st, 1888, the Government nurseries of Berlin distributed 105,778 young trees and shrubs, to be used in adorning the city and its suburbs, and 82,686 flowering and foliage plants. The nurseries which supply plants for the use of the city now contain nearly 4,000,000 specimens and are steadily being enlarged.

At a meeting of the New York Academy of Science held on December 3d, at Columbia College, Dr. H. N. Jarchow read a paper on the training of foresters in Europe, and the economic success that has been attained in forest culture there, and Professor E. B. Southwick, Secretary of the New York State Forestry Association, gave a brief history of what had been accomplished by that body.

Among the interesting plants detected by the Abbé Delavey in Yun-nan, and recently sent to France, there is a Fig (*Ficus Ti-Koua*), with edible fruits of the size and color of a Lady Apple, according to the *Revue Horticole*, which grow and ripen under ground. The plant is a shrub, with trailing, semi-subterranean branches, and large obovate-elliptical leaves. The Figs are called by the Chinese who eat them *Ti-Koua* or earth gourd.

A collector recently sent out by Dr. Dieck, a well-known German nurseryman and dendrologist, reports that the Rose hitherto sold in Europe as the true source of attar, and called "Rose de Kazanlik," is not to be found in the vicinity of Kazanlik at all. The true Roses for the production of attar, he says, are *Rosa alba suaveolens* and a variety of *Rosa Gallica*. Specimens of these plants he has been enabled to send to Germany, in spite of the strict laws which now prevail in the Danubian provinces against the exportation of attar-producing Roses.

It is well known that the slopes of Krakatoa, in the Strait of Sunda, and the regions around its base, were wholly desolated a few years ago by a terrible volcanic eruption, which covered them so deeply that all seeds as well as vegetable growths were destroyed. Almost immediately, however, it is said, Nature began to repair her ravages in a way that most interestingly illustrates her processes in early geological epochs. Fresh water Algæ soon covered the wide stretches of cinders and pumice-stone, forming a glutinous layer in which seeds could take root; and a couple of years after the eruption Ferns and Phanerogams had everywhere established themselves, the species being similar to those which take possession of newly formed coral islands.

An important horticultural exhibition will be held next year in Berlin, and will be open to all nations. The schedule of prizes contains 235 classes of stove or warm house-plants, 377 classes of green-house and hardy plants, besides classes for fruits, vegetables, nursery stock, tools and machines used in horticulture; and there will be a section in which the classes include the morphology, anatomy and growth of plants; physiology, useful and poisonous fungi; officinal and economic plants, plant geography, etc. The exhibition is expected to bring out the close relations which exist between architecture and horticulture. Visitors to Berlin, moreover, will have an opportunity to examine some of the finest examples of landscape gardening which can be seen now in Europe.

The attendance at the annual meeting of the American Forestry Congress, held at Atlanta last week, was unusually large, and the papers read and the discussions of topics presented were of the most instructive character. The officers elected for the year were: President, Governor J. A. Beaver, Pennsylvania; Vice-Presidents, H. G. Joly, Quebec; J. D. W. French, Boston; Charles Mohr, Mobile; Herbert Welsh, Philadelphia; George H. Parsons, Denver; Recording Secretary, N. H. Egleston, Washington; Treasurer, Charles C. Burney, Philadelphia. Mr. B. E. Fernow, Chief of the Forestry Division of the Department of Agriculture, was compelled to decline the office of Corresponding Secretary, which he has most acceptably filled since the organization of the Congress, and J. B. Harrison, of New Hampshire, was chosen as his successor.

Mr. Meehan tells the readers of the *Country Gentleman* that in an old Indian village of Alaska, the people used to carve their genealogies on huge poles before their doors, by means of hieroglyphics. One generation cut its crow or its bear, or whatever the tribal style may be, on it; and so on, one above another, generation by generation, to the top. They do not do it now, but the moss-grown and neglected old poles, some two feet thick and perhaps twenty feet high, are still standing. On the tops of these poles, Hemlock and Spruce trees

have sprouted and grown; great bushy trees, ten or fifteen feet high, and as handsome as any seen in a nursery. In some cases the roots have gone down through the old poles, twenty feet or more, to the ground, splitting the poles open and exposing the roots, which perhaps will be, when the old poles rot away, real trunks to support the trees.

It is said that American competition has greatly interfered of late years with the resin industry of the districts of the Gironde in France, at one time the chief support of a large portion of the inhabitants. About a third part of the land in the department once consisted of barren sandy wastes called *Landes* upon which nothing but Pines would grow. *Pinus maritima* was planted in large quantities, and despite the recent falling off of the trade in resin, it still affords many sources of revenue, the most important of which is the furnishing of pit-props for use in the English mining districts. One hundred and seventy-five thousand tons of these props are annually exported. Young trees are also sent to England in large quantities to be employed in paper making; railway sleepers and telegraph poles are supplied for many parts of France, and an illuminating oil is made from the resin, which readily finds local buyers, as it burns well, is even cheaper than kerosene, and, moreover, is non-explosive.

According to a correspondent of *The American Architect and Building News*, seven crops of forage are annually gathered from the plains of Lombardy. The district is naturally well watered, the great reservoir of the Alps being near at hand and a number of rivers traversing it on their way towards the Po. But a natural supply of water would not suffice, during the long, hot summer of Italy, to preserve the plain in such a phenomenal state of fertility. A vast expenditure of labor and skill has for ages been devoted to works of irrigation. At least as early as the twelfth century they were well under way, under the direction of the monks in a branch house of the monastery of Clairvaux, which had been established by St. Bernard near Milan. During Renaissance times they were carried on by some of the greatest architects of Italy, Leonardo da Vinci, for example, having conceived the idea of connecting the Mincio and the Tessina by means of a canal. And to-day the whole plain is a net-work of canals and reservoirs which cannot be exhausted by the fiercest drought.

Among recent devices for preserving timber is that advocated by Filsinger, who recommends impregnating the wood with a weak solution of aluminium chloride. Another suggestion is, that a solution of gutta-percha, obtained by a mixture of two-thirds gutta-percha and one-third paraffine heated together until the gum melts, shall be forced into the cells of timber from which the air has been previously exhausted. The gutta-percha, as it cools, hardens and completely fills the cells. But the latest suggestion is that of Von Berkel, who proposes first to impregnate wood with a saturated solution of lime water or milk of lime. The board is then dried and placed in a vacuum cylinder and impregnated with a mixture of silicic acid and mineral oil or some other fatty or bituminous substance, by pressure applied for a considerable time, when a process of petrification takes place and a kind of asphalt rock is formed within the wood cells. The industrial value of this invention has not been demonstrated yet, although the possibility of using water gas for these purposes, of which Von Berkel's plan appears to be only a modification, has long been recognized.

There seems to be no end in England to the making of horticultural societies. The attention which the English give to minor branches of the art is shown by the flourishing existence of a National Auricula Society and a National Carnation and Picotee Society, both of which hold well-attended annual meetings and large exhibitions. Speaking of the Auricula, *The Garden* recently quoted from a book published in 1764 to prove that even at this time this flower was high in public favor. Indeed, the author of the book in question said of the Auricula that it was "formerly the pride of English gardeners and florists," whose success in raising new seedling varieties greatly excited the envy of their Dutch rivals. But there could have been nothing to complain of in his own time, for he declared that he had known good new seedling Auriculas to sell for seventy guineas apiece. As *The Garden* remarks, "When we consider the value of money in those days as compared with the present, this does seem an enormous sum, for there could have been no gambling with so perishable a plant as there was with the Tulip in the days of the Tulip mania in Holland." A single guinea is now considered a very high price for a new Auricula in England.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, DECEMBER 19, 1888.

Forests and Civilization.

THE essential facts, principles and ideas of the subject of Forestry have not yet become a part of the mental possessions of the people of this country. It takes time for any new subject to obtain a real place in the mind and consciousness of a nation. Just and practical thinking in regard to our forest interests and their relation to the national welfare is possible only after a considerable acquaintance with the facts upon which the science and practice of Forestry depend. Some degree of familiarity with the subject is necessary to enable people to recognize its real nature and importance. Opinions which have no basis of knowledge are of slight value—are, indeed, hardly worthy of the name; and some knowledge of elementary facts and principles must be domesticated—made at home—in the minds of the people, in order to prepare them for intelligent action regarding our forest interests.

We have not yet reached this stage in the development of our national intelligence in relation to this subject, and much iteration and illustration of the truths which have been established by observation and by the experience of thousands of years, will be required before they become a part of the national consciousness; before these truths can be assimilated and incorporated into the mind and habitual thought of the American people. This indispensable repetition of the essential facts and ideas of the subject must be urged, and an impression produced, as rapidly as possible, as the process of the destruction of our forests does not wait for the necessarily slow advance of popular intelligence.

All the money that has been obtained from the Adirondack forests might have been gained without injury to the woods themselves, leaving every acre still clothed with prosperous and productive forests. But, by reason of ignorance, indifference and mismanagement, much of this region is to-day almost as completely and irrecoverably ruined as if it were covered a thousand feet deep with boiling lava. The people who are interested in great schemes and enterprises for irrigation in the western part of this country appear to be mostly unaware of the essen-

tial fact that if the forests of that region are destroyed, there will be a great loss of the water needed to carry out any plan or system whatever.

When the pine supply of Wisconsin and Minnesota is exhausted there is likely to be a very considerable movement of the population out of the states which have depended upon this region for lumber. Other sources of supply will be too far away, and the increased cost of timber will make the difference, for many thousands of people, between being able and not being able to live in that country. If the people thus evicted by irresistible economic conditions should all go out at once, the spectacle would be impressive and dramatic. But, as the movement will take place gradually, few persons will give it attention or recognize its cause. Yet the results in the end must be the same.

The ultimate and inevitable effect of the destruction of our forests will be the impoverishment of some regions of our country; and, as a consequence of this wanton and hideous waste of our national resources, millions of our people will be compelled to live on a lower plane of civilization, and with less means for physical subsistence and comfort, and for development in all that constitutes civilized life, than would have been accessible to them if our forests had been intelligently cared for. There is no subject which at present more urgently requires the attention of journalists, educators and statesmen, and of all thoughtful men in this country.

Christmas Green.

EVERY morning for a week past the steamboat Minnie Cornell, from Keyport, New Jersey, has come to her pier loaded with "rope" and "fancy green." "Rope" is the trade name for the cables made of Club-moss and occasionally of Hemlock spray, and used for looping into festoons or twining about columns in Christmas decorations. "Fancy green" includes the wreaths, stars and other designs, manufactured chiefly from the leaves of Holly, Laurel and Rhododendron, together with Mosses, green or gray, from Oak trunks and Cedar boughs, scarlet berries of the Black Alder, the bluish gray fruit of the Juniper, the scarlet and orange fruits of the Bittersweet, not to speak of Grasses dried and dyed in fearful and wonderful colors. The little steamer has more than once carried 60,000 yards of the festooning material, and 1,500 dozen stars and wreaths at a single trip, and the entire amount of "rope" brought to this market during the season would reach from New York to Boston. The very first Christmas green sold in this city came from Keyport. Some forty-five years ago the wife of a Monmouth County farmer gathered enough Ground Pine to fill a sheet with the four corners tied together, and shipped it on a sloop with her poultry. It proved a lucky venture, and ever since, the people of Monmouth County have held almost a monopoly of the industry, although both the species of Club-moss most largely used, *Lycopodium dendroideum* and *L. complanatum*, were practically exterminated from that region years ago. They are still abundant, however, in Connecticut, some parts of northern New York, and Massachusetts, and are shipped to New Jersey in such quantities that large dealers buy them by the ton, and the manufacture of these festal wreaths and cables gives employment to the wives and daughters of many farmers after the fall work on the farm is over.

The trade in Christmas-trees began in 1851, when Mark Carr yoked up his oxen and hauled from the Catskills to the steamboat landing on the Hudson two sled-loads of young Balsams, and paid a silver dollar for the privilege of selling them on the corner of Vesey and Greenwich Streets. At least 150,000 trees have been piled up along the docks of the North River during the last week, and since the days of Mark Carr many a dealer has been glad to pay a hundred dollars for a corner privilege for holiday trade in Christmas trees. About half of the trees this year come from

Maine, the remainder from the Berkshire Hills, the Black River country in the Adirondacks, and the Catskills. Good trees in the Catskills are becoming scarce, however, and the woodsmen of those mountains are looking elsewhere for their material. Short jointed, stocky trees with perfect whorls of branches at the base of each annual growth, are the most sought for, and the Maine trees, as a rule, command rather higher prices than any others. The trees come up thickly where hard-wood timber has been cleared away, and if they are cut above the second or third joint, one of the limbs soon turns upward and becomes a leader to furnish another Christmas-tree. In this way the same land is cut over several times. Fortunately the Balsam Fir is about as nearly worthless for any other purpose as any of our native trees, and therefore the waste of cutting so much young timber is not serious. A few Black Spruces come among the Firs, and Hemlock boughs, which, oddly enough, are made to do duty as Palm branches in some church services, are in growing demand every year. Trees from Maine are shipped as far south as Baltimore; and of late years large quantities of Holly branches, mostly from Maryland, since the limited supply in New Jersey is nearly exhausted, are sent as far north as Boston. Within two or three years the Mistletoe has been sold here in a few shops and even on the streets, but in spite of its association with Christmas festivities in Old World traditions, it has filled but a small place here in the regular market of Christmas green. And yet this parasite is common on the Gum trees of southern New Jersey, and it is never so beautiful as at this season with its transparent berries clustered among its evergreen leaves.

The plan for the Leland Stanford, Jr., University, printed upon another page of this issue, records something more than the ideas of the acknowledged master of landscape art with regard to a great problem. It records the occurrence in our country of new and vast problems which spring from the wonderful development of commerce and the concentration of enormous wealth in the hands of individuals often willing to use it for the public good. And it records that the time has passed, or is fast passing, when great projects, more or less rural in their character, are to be undertaken blindly or without the counsel of trained specialists. The fact that an artist is called upon to locate the building and model the grounds of a University, to cut up to the best advantage the grounds of a suburban land company, or to suggest the proper approaches to a rural railroad-station, shows that the American people have made noteworthy progress during the last few years in artistic and economic education.

The value of a thoroughly studied plan, such as Mr. Stanford has secured, can be appreciated only by comparing it with the plans of some of the old Universities of this country, which have been built up piecemeal, without reference to any consistent scheme of general utility or convenience, and just as individual fancy or momentary convenience dictated. An examination of Mr. Olmsted's plan must show how convenience, to say nothing of appearance, is lost, and how economy of time and space is sacrificed, whenever a scheme of this nature is undertaken without the aid of a carefully-prepared plan.

The United States is now taking the lead among nations in the revival of the art of landscape-gardening, once almost lost from the face of the earth, and is adapting it to the solution of some of the greatest economic problems in modern life. The movement is still young, yet it shows itself more or less distinctly in every public improvement recently undertaken in this country, and still more unmistakably in the growing interest and appreciation of the American people for all that is good, and, therefore, beautiful, in Art applied to Nature.

A horticultural and technical college has lately been opened at Swanley, near London, under the auspices of the National Fruit-growers' League, an association formed for

the purpose of encouraging the general growth of fruit in Great Britain, as a remedy for agricultural depression. Immense quantities of imported fruit, especially apples, are consumed in Great Britain, and many persons claim that all this fruit, and a great deal more, can be better grown at home than anywhere else, and the land which cannot be used profitably in growing wheat can be made to pay large returns if covered with orchards, and that fruit-growing will give employment to many persons now idle. The trouble with English agriculture is too deep to be cured or even greatly mended through apple-growing; but there is no reason why the new college may not prove a useful institution. In it, we are told, "work for the mind will accompany work for the body, and thus the physical and mental faculties will be equally developed;" and, having settled the somewhat momentous question of "what shall we do with our boys?" it is going, so its founders promise, to provide for the future of the young women of England. The working of the new school will be watched, therefore, with interest and anxiety by the heads of large families.

The wood used in the manufacture of spools is an item of no small importance already in the forest-crop of some of the Northern States; and the demand for it is increasing rapidly. The wood of the Canoe Birch is used almost exclusively for this purpose, although the Gray Birch is used also in small quantities. Maine, and especially Piscataquis County, is now the headquarters of the spool-wood industry; and a large number of vessels loaded with spool-wood have sailed direct, during the summer, from Bangor to foreign ports. The wood for this purpose must be clear and entirely free of knots and other imperfections; it is sawed into squares, of different dimensions, four feet long, which are delivered to the spool-makers tied into bundles. Several million feet of Birch timber—probably twelve or fifteen—are cut annually in the Maine forests alone for this purpose. The amount of Canoe Birch lumber standing in our northern forests is still large, and as the trees grow rapidly up to a certain age, the supply will not be exhausted soon, although the consumption is now increasing much more rapidly than it ever has before.

The Story of Shortia.

OUR illustration upon page 509 represents one of the rarest and most interesting plants of North America. It is interesting from the peculiar structure of its delicate flowers, its botanical relationship, and the geographical distribution of the small family to which it belongs, which, as now defined, consists of but half a dozen genera and only nine species, which are all, excepting the two species of *Diapensia*, confined to eastern North America and eastern Asia.

The great interest of our *Shortia*, however, is found in the history of this plant during the past century, and in the fact that among all the plants studied and described and classified by Asa Gray, this little herb most excited his interest. American botanists never think of the man whom they all delight to look upon as their master and to remember as their friend without thinking, too, of this humble little plant, which properly occupied a conspicuous place upon the gift which a few years before his death they brought to him with words of affection and encouragement.

Professor Gray was in Europe in 1839, and in examining the herbarium of the elder Michaux, preserved in the Museum at Paris, found an unnamed specimen of a plant, with the habit of *Pyrola* and the foliage of *Galax*, of which only the leaves and a single fruit were preserved, and which had been collected, the label stated, in the "*Hautes montagnes de Caroline*." This specimen at once arrested his attention; and after his return, two years later, from his first botanical journey into the Carolina mountains, where he had searched in vain for Michaux's plant, he ventured to describe it, and to point out its probable affinities upon the strength of the scanty material in the Michaux herbarium, dedicating it to Dr. C. W. Short, the author of a catalogue of the plants of Kentucky, and fifty years ago an astute observer and capital collector of western plants, which he distributed with an unstinted hand among the principal herbaria of the United States and Europe.

Nothing more was seen of *Shortia* for a long time, although no botanist ever visited the mountains of Carolina (and the number after 1866 was considerable), without carrying a special commission from Cambridge to bring back a specimen of Michaux's little plant, in which Dr. Gray's interest became stronger than ever when, in studying in 1858 a collection of Maximowicz's Japanese plants, he recognized in that botanist's *Scizocodon uniflorus* another species of *Shortia* almost identical with the Carolina plant. The Japanese specimens, curiously enough, were in the same condition—that is, although the calyx and pistil of the flower were preserved, there was no trace of either corolla or stamens.

These specimens, while they confirmed the validity of the genus, threw no light upon the Carolina plant, which botanists now hunted for more assiduously than ever. The keenest-eyed plant-hunters looked for it in vain year after year in all the region in which Michaux was supposed to have traveled; and the search was almost given up as hopeless, when in May, 1877, *Shortia* was found accidentally by a youth, G. M. Hyams, upon the banks of the Catawba River, near the town of Marion, in McDowell County, North Carolina, at a considerable distance from the high mountains to which Michaux's label assigned the plant. The new specimen fell into the hands of the young man's father, a professed herbalist. His knowledge of botany, however, was not great; and it was not until the following year that he discovered, with the aid of a correspondent, what a treasure he had.

These new specimens made when the plant was in flower confirmed at once Professor Gray's original ideas of the proper relationship of his genus, and enabled him to complete its characters and remodel the family to which it belonged.*

There seemed to be nothing more left to say about *Shortia*. It was figured and described and discussed, and even introduced sparingly into cultivation, although its stay in gardens was a short one; while the enterprising discoverer reaped a rich harvest during a year or two by selling plants (and, it is to be feared, by exterminating them) for herbarium specimens, at extravagant prices. Professor Gray, however, clung to the belief that Michaux's label could be depended upon, and that the real home of *Shortia* was in the high mountains. He regarded the station upon the Catawba as an outlying post, to which he suggested the plant might have been washed down, and still believed that it was to be found about the head-waters of the streams flowing eastward from the high Black Mountain range. This region was again carefully examined, but without result, and the search for *Shortia* was practically abandoned.

There is still, however, another short chapter to relate in the history of this little plant. I visited, two years ago, in the autumn of 1886, the mountain region of North and South Carolina, which lies about the head-waters of the Keowee River, the great eastern fork of the Savannah, for the purpose of gaining, if possible, some insight into the origin of *Magnolia cordata*, a species which was first described in Michaux's North American Flora, but had not been seen anywhere growing wild during the present century, although preserved and generally disseminated in gardens. Michaux left Augusta, Georgia, towards the end of November, 1788, for the purpose of securing a supply of roots of what he called at that time *Magnolia cordata*. This was not, as I was afterwards able to show,† the *Magnolia cordata* of the Flora, founded long afterwards in Paris by Richard upon a specimen of *M. acuminata*, but the *M. Fraseri*, a species which had been discovered a few years earlier by the younger Bartram, the first botanist who explored the Carolina mountains. Michaux, in spite of a serious attack of fever, reached the head-waters of the Keowee on the 9th of December, and although weakened by sickness and hunger, and seriously impeded by the intense cold which he encountered in this elevated region, proceeded to explore the neighboring high mountains in search of a supply of young *Magnolia* trees for his Charleston nurseries. On the day of his arrival he noted in his journal that he had discovered what he called a "*Nouvel Arbuste a. f. dentelés rampant sur la Montagne.*" I had taken occasion before undertaking this journey to examine the manuscript diary kept by Michaux during his stay in America, preserved in the library of the American Philosophical Society; and I had noted the directions he had written down with much detail for finding his "*Arbuste*"—which evidently had interested him, as it is the only plant which he mentioned in

the whole diary in this way—in the hope of identifying his plant, which, as this region had not been visited again by any botanist, might prove something new, or at least imperfectly known. The idea that the plant might be *Shortia* was hardly entertained. It did not seem possible that Michaux, under any circumstances, could have mistaken *Shortia* for a shrub; and Dr. Gray, who had examined the diary either just before or immediately after his first journey to Carolina, if he noticed this entry at all, certainly never associated it in any way with the plant which he wanted to find more than all others. Had he done so he would have visited, or sent some of his correspondents to visit, the head-waters of the Savannah, a region which, for some reason, never attracted his attention, although it was by this route, following the old Indian trail from the coast to the Cherokee country, that all the early botanists penetrated to the mountains.

It was possible, with the aid of the journal, to find, without much trouble, the spot where Michaux had camped in December, 1788, and to trace his footsteps upon the different excursions which he made into the mountains from this camp. The two torrents which he described, as descending in a rough and tumultuous course from the high mountains to form the Keowee, are now known as the Toxoway and the Horse-pasture. The little fertile plain which Michaux found at the junction of these two streams still exists, as does the foot-path, since trodden by the feet of many moonshiners, which led from the right bank of the river a hundred paces below the junction of the two streams into the mountain facing the north. It was by the side of this path that Michaux, just 100 years ago this month, discovered his "*Arbuste*," with denticulate leaves, and here, ninety-eight years later, I found *Shortia*.

The evidence seems conclusive that the two plants are one and the same, or, if it was not in this exact locality that Michaux gathered the specimen preserved in the Paris Museum, it was in this immediate neighborhood, where *Shortia* is now known through the subsequent explorations of Mr. F. H. Boynton, of Highlands, North Carolina, to be abundant.

Mr. Faxon's drawing shows so clearly the habit and structure of *Shortia*, which, moreover, has been frequently described in purely technical journals of botany, that nothing further upon these subjects need be written now. Its nearest American allies are *Galax aphylla*, a beautiful evergreen herb, with tall, erect racemes of small pure white flowers, peculiar to the wooded slopes of the southern Alleghany Mountains, and the familiar *Pixie (Pixidantha barbata)* of the New Jersey Pine barrens. There is in Japan one species of *Shortia* (*S. uniflora*), and possibly two, as there exists a rude portrait in an old work upon Japanese botany, in which what is evidently another species of *Shortia*, almost identical with the American plant, is represented. In Japan, too, are two species of the nearly related *Schizocodon*, while in Thibet occurs *Berneuxia*, of the same family of *Diapensiaceæ*, of which the type is *Diapensia*, with two species, one widely distributed in boreal regions and the other confined to the Himalayas.

C. S. S.

Plan of the Leland Stanford, Jr., University.

SENATOR STANFORD, of California, when he determined to commemorate the short life of his only son by erecting a university in his memory, had the practical good sense to call to his assistance an artist trained by long years of experience in dealing with large questions of rural and urban improvement. The answer to the problem which was given to Mr. Olmsted to solve is found in the plan, a part of which is printed upon page 508 of this issue of GARDEN AND FOREST. The problem was an interesting and remarkable one. No one before, it is safe to say, has deliberately set about building a great university, with a university town and all the appliances thought necessary for a modern education, in a situation remote from any great centre of population. Mr. Olmsted, therefore, has had to deal with questions which are quite unlike those found in his own experience, and for which there are no precedents in the work of other landscape gardeners.

The ground which he has studied with reference to this plan embraces about 7,000 acres, the map here presented covering an area of about one mile in length by half a mile in width. It is situated in the San José valley, about thirty miles from San Francisco, overlooking the head of the Bay of San Francisco, and not far from Menlo Park, the suburban or country-home of several prominent Californians. It occupies the rolling slopes of the low hills of one of the interior Coast Ranges. The heights extending above and towards the left

*Asa Gray in *American Journal of Science*, 3 ser. xvi., 483; *Annales Sci. Nat.*, 6 ser. vii., 171, t. 15.

†*American Journal of Science*, 3 ser. xxxii., 1160.

of the portion shown in the plan are covered with the remnants of what was once a fine forest of Firs and Pines and Redwoods, and over the lower ground are scattered widely the noble Oaks which give to the scenery of the California valleys the peculiar park-like aspect which distinguishes them from those of the rest of the United States.

Mr. Olmsted's plan embraces, in addition to the immediate surroundings of the University, the site for an arboretum, in which it is proposed to gather the arboreal vegetation of California and of other regions of the world with climates similar to that of California, and an artificially planted forest of several hundred acres, which will serve as a model to

coast range and is mainly rugged and semi-mountainous. . . . The remainder is a plain, with a moderate inclination to the north-east. . . . The central buildings of the University are to stand in the midst of the plain. . . . This has been determined by the founders chiefly in order that no topographical difficulties need ever stand in the way of setting other buildings as they may, in the future, one after another, be found desirable, in eligible, orderly and symmetrical relation and connection with those earlier provided.

This point being fixed, the leading purpose of so much of the plan as is represented in the sketch is: First—to provide for convenient and economical use, by large numbers, of the means of research and instruction to be offered in the central buildings. Second—to provide, in the arrangements devised for this purpose, an outward character, suitable to the climate of the locality, that will serve to foster the growth of refined, but simple and inexpensive, tastes. Third—to favor the formation, in connection with the University, of a community, instructively representative of attractive and wholesome conditions of social and domestic life.

The four sides of the central quadrangle are to be formed by a continuous arcade of stone, eighteen feet in height, twenty feet in depth and 1,700 feet in length. Opening from the arcade are to be a series of structures for class-rooms, lecture-rooms, draughting-rooms and rooms for scientific investigation and instruction. Each of these is to be one high and airy story, and in all desirable cases to be provided with special arrangements for light and ventilation above as well as on its four sides. . . . Of several reasons for limiting these structures to one story, the principal is, that in a building of two or more stories the necessity of providing on the lower for any cross partitions, or for the support of any considerable weight in the superstructures, has everywhere in older institutions been found to stand in the way of desirable revisions of interior plans. It is considered that anything thus likely to hinder the ready adoption in the future of new inventions or methods and conveniences for liberal education should be avoided. . . . The areas assigned to the second and third quadrangles (B and C), are to be used as University Athletic Grounds until wanted to be built upon. When taken to be built upon, the next blocks of the reservation (D, E) are to be substituted as Athletic Grounds, and so on. Those parts of the reservation not in use as thus proposed, are to be fields of the Agricultural Department of the University.

The public streets are to have borders ten feet in breadth, planted with shade trees. These borders are to be graded and planted at once, and all land within the limits of the plan not to be presently occupied for some one of the purposes above stated, is, as soon as practicable, to be closely planted. The plantations are to be afterwards thinned before they become crowded, and clearings are to be made among them, as, from time to time, space is wanted for buildings. Building sites not expected to be very soon occupied by buildings are also intended to be inclosed with hedges. By these two expedients it is hoped that the immediate surroundings of the University may be prevented from taking on at any point the usual aspect of "vacant lots" in the outskirts of towns and villages, which, in California, because of its dry summer climate, is apt to be even more forlorn than in the Eastern States.

That part of the public way, divided by a strip of garden ground, upon which the Library and the Museum buildings (J, J) face, is to be carried upon a retaining wall with a parapet, making it a terrace. The five compartments immediately to the northward, below the terrace, are to be depressed areas, each occupied by a mass of shrubbery, over which a broad view of the principal buildings of the University will be had from the head of the avenue (Q). These areas would be fields of turf were it not that satisfactory turf in California can be maintained only by profuse irrigation, and irrigated ground, unless kept with extreme neatness, is liable to be a source of miasmatic exhalations. It is considered that the University should not have the difficulty and expense imposed upon it of the constant mowing, rolling, sweeping and watering of such large open spaces as would thus be made necessary. In this and in all other respects, the landscape and the architectural design have in view ideals that pertain rather to the south than to the north of Europe or to the Atlantic States.

This work will be studied with profound interest by landscape gardeners, and its gradual development will be watched with interest by all persons interested in the spread of education and in the growth of American civilization.

It may be added that substantial progress has already been made in the construction of the university buildings from plans prepared by Messrs. Shepley, Rutan and Coolidge, of Boston.

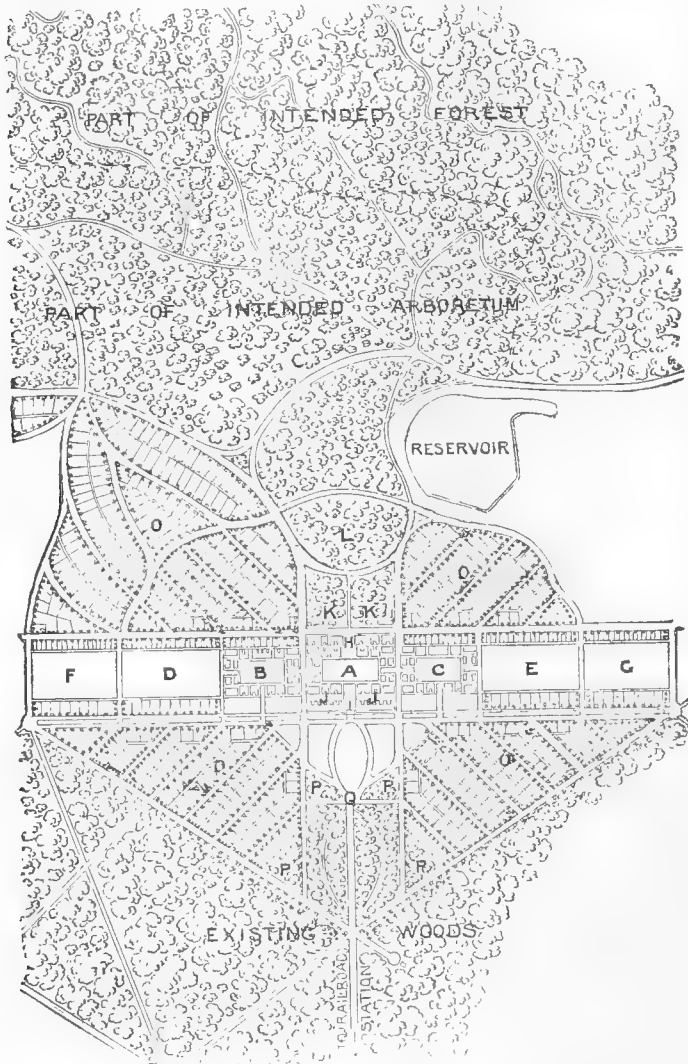

Fig. 79.—Plan of the Leland Stanford, Jr. University.

A: The central quadrangle, with buildings now partly under construction. **BC:** Sites for adjoining quadrangles, with proposed buildings. **DEFG:** Four blocks of land of form and extent corresponding to the above, to be held in reserve as sites for additional quadrangles and proposed buildings. **H:** Site for University Church. **I:** Site for Memorial Arch. **J:** Sites for University Libraries and Museums. **K:** Site for buildings of Industrial Department of the University, now partly under construction. **L:** Site for University Botanic Garden. **OOOO:** Four districts laid out in building lots suitable for detached dwellings and domestic gardens, with public ways giving direct communication between them and the University central buildings. **PPPP:** Sites for a Kinder Garten, a Primary School, an Advanced School and a School of Industry and Physical Training. **QR:** A direct Avenue between the central quadrangle and a proposed station of the Southern Pacific Railroad, with bordering groves and promenades. Space is allowed in the wheel way for a double track street railway.

planters on the Pacific coast. It is needless, of course, at this time to call attention to the importance of this particular part of Mr. Olmsted's comprehensive scheme, or to urge the necessity for establishing an Arboretum and Botanic Garden in California, where all the climatic conditions are so unlike those of the rest of the Continent, that they may be made to play an important part in extending the sum of human knowledge with regard to the trees and plants of the world.

The leading motives of the scheme are briefly summarized by Mr. Olmsted as follows:

The ground covered by the upper portion of the sketch, and extending some miles beyond, is a part of the foothills of the

Foreign Correspondence.

London Letter.

THE attempt to induce English farmers to plant their fields with Tobacco instead of Wheat and Potatoes having proved abortive, efforts are being made to induce colonial farmers to try Tobacco for the English market. A prize is offered by the London Chamber of Commerce for the best specimen of colonial-grown Tobacco, of not less than 400 pounds. Without protection, however, it is not clear how the present supply can be superseded by what must obviously be an inferior article.

Begonias pay in England better than Tobacco, and I hear

flowers, which are open together. The individual blooms, male and female, attain the size of three inches or more in diameter, and are composed of six to eight large, oval petals, which give them the shape of *Anemone fulgens* or of *A. Japonica*. A nearly complete range of colors, from pure white to scarlet, with various shades of pink and carmine, is to be found in this new race, which produces a beautiful display of bloom at a season when the tuberous Begonias are over—that is, in November." The most marked character in this new race is the number of petals in the flowers, the common ones having four only in the male flowers and six in the females; the increased number in M. Lemoine's latest success is owing to the eight-petaled character of one of the parents, *B. octopetala*.

Fig. 80.—*Shortia galacifolia*.—See page 506.

we have still another race of these plants to add to those which have become universally popular for out-door bedding and green-house decoration. Mons. V. Lemoine, of Nancy, already famous as the raiser of some first-rate Gladioli, Pelargoniums, etc., has succeeded in crossing the very distinct species, *B. octopetala*, with some of the finest of the tuberous section. He writes to Dr. Masters: "The result of this cross is a magnificent one, and the new race, '*Octopetala Lemoinea*,' is one of the handsomest which I have ever raised. The root is somewhat irregularly lengthened, black, intermediate in shape between that of the two parents. The stem is herbaceous and short, so that the leaves seem to be radical; they are broad, undulated, of a glossy green, with round, hairy stalks. Each plant bears from six to eight erect flower-stalks, thick and hairy, about two feet high, and each supporting from five to seven

Mr. Rivers, of Sawbridgeworth, famous for first-rate work among fruit-trees, the raiser of some of our finest Peaches, Nectarines, Plums, etc., and the pioneer of house-cultivation for orchard-trees, has gathered a very fine collection of Oranges, Citrons, Lemons, etc., which he cultivates by the thousand, and fruits when only two or three feet high. Altogether he has over fifty distinct kinds, which are true to name and comprise all the very best commercial sorts. I saw them a few days ago, and was especially charmed with the show-house of well-fruited plants, none in pots above eight-inch size, and some with over a score of large, beautiful fruits upon them. I was surprised to find that these pot-grown Oranges were better in flavor and much more juicy than those imported. Mr. Rivers supplies the colonies and also America with plants from his nursery, which, being grafted and carefully named, are much more reliable than

Fig. 81.—The Washington Oak at Fishkill—See page 511.

those raised from seeds. Indeed, these plants, except the species, are no more likely to reproduce themselves from seeds than Apples or Plums are. For the decoration of conservatories and houses in winter these small plants are of considerable value. They are grafted on the Lemon when young, grown in sunny, intermediate houses, and when the fruits appear the plants are kept in a temperature never lower than 60°. The high, regular temperature induces the formation of pulp, and prevents that abnormal

thickness and unevenness of rind which is invariable in fruits ripened in an ordinary green-house.

The charming little Daffodil known as *Narcissus monophyllus*, or the White Hoop-Petticoat, is the first to develop its pure white blooms, and they remain fresh on the plants for several weeks. It is grown at Kew for the decoration of the cool green-house. The bulbs are planted in a sandy, peat soil, which is kept moist while the plants are in leaf and flower, but quite dry when these are over. All through the

summer the pots containing the bulbs are exposed to full sunshine on a dry shelf. This is the secret of growing and flowering the White Hoop-Petticoat.

Mr. Moore, of the Glasnevin Botanic Gardens, near Dublin, has added another to the half dozen or so excellent kinds of *Eucharis* already in cultivation. The new one is a very distinct variety of *E. Amazonica* (*E. grandiflora* of botanists), characterized by the purity of its flowers, those of the type having a green tinge on the inside of the tube; there is also a difference in the form of the three inner segments of the perianth. The foliage is much shorter and thicker in texture in the new one than in the type. Mr. Baker has named the variety *Mooreana*. We have now, in addition to the two mentioned, *E. Sanderi*, *E. Mastersi*, *E. candida* and *E. subdentata*, all of them large-flowered and of great value on account of the freedom with which their flowers are produced under ordinary treatment, it being by no means unusual for these plants to flower three or four times in the same year. The once dreaded mite, which is often found on the bulbs of these plants, has proved much less deadly than it was supposed to be; at all events, one rarely sees bulbs which are unaffected by it, and hosts of other bulbs besides *Eucharis* are just as much subject to it. A famous Dutch bulb-grower, on being asked if the mite did him harm, replied that it had been on his bulbs ever since he knew them, which was more than forty years, but it did no harm. If a bulb sickened the mite increased, but strong bulbs were unaffected by it. So far as my experience goes, this is true.

Cypripedium insigne Sanderæ is the last sensational Orchid, a small plant, with a single growth and one flower, having brought seventy guineas at an auction sale on the 16th inst. It differs from the type in being devoid of spots, the pouch and petals being yellow and wax-like, the dorsal sepal yellow below and white above. It was imported among a batch of *C. insigne* by Mr. Sander.

Two of the best Orchids flowering here now are *Lalia autumnalis*, with its variety *atrorubens*, and *L. anceps* in all its numerous forms. These two species are Orchids for the million, as they are easily grown, they are permanent stayers when once established, and they flower freely every autumn, lasting about six weeks in perfection.

November 23d, 1888.

W. Watson.

The Washington Oak at Fishkill.

ALL strangers who visit Cambridge, in Massachusetts, look with interest upon the remnants of the venerable Elm tree under which Washington sat when, on the 3d of July, 1775, he assumed command of the Colonial Army. Not less interesting from its association with the General of the American Army, although much less well known, is the Oak which is represented in our illustration upon page 510.

Washington's headquarters remained on the west bank of the Hudson, between Newburgh and New Windsor, from the spring of 1782 to August 18th, 1783; and during this time he crossed the river frequently for the purpose of visiting the troops in camp upon Fishkill Plain, near the village of that name. The most convenient landing-place on the east bank was upon a long, low point of land formed to the north of the mouth of Fishkill Creek, known as "*Presqu'île*," and here, according to the tradition of the locality, under two large Oak trees, Washington always mounted and dismounted from his horse as he started and returned from the camp.

One of these trees appears in our illustration; its companion was blown to the ground on the 10th of August, 1881. The story of Washington's connection with these two Oaks seems to be abundantly substantiated. The Commander-in-Chief was often accompanied on these excursions from his headquarters to the camp at Fishkill by his Adjutant-General, William Denning, whose son, also William Denning, at that time fourteen years of age, was sometimes allowed to join the party. The impressions made upon the boy by the incidents of this period were not effaced; and many years later, in 1822, after a life of travel and adventure, he returned to the Hudson and purchased from a member of the Verplank family the point of land, and the old Oaks, still associated in his mind with the Commander-in-chief of the American Army and the first President of the United States. The daughter of the second William Denning, to whom we are indebted for these facts, still inhabits the old mansion built on "*Presqu'île*" in 1813; and her life and that of her father span the years which separate us from the days of Washington and the Colonial Army.

The tree is a Chestnut Oak (*Quercus Prinus* of botanists), still healthy and vigorous, and standing directly at the top of the low

river-bank. The trunk girths, at the present time, twenty-one feet, and, judging from the age of its companion, which was blown down seven years ago, eight or ten centuries may have passed since the acorn from which it sprang fell to the ground.

Our illustration is from one of a series of photographs of the old trees and the historical country places of the Hudson River, made by Mrs. Winthrop Sargent. The photograph brings out admirably the striking character of the bark of this particular species of Chestnut Oak. It is dark brown, and, on old trees, very thick and deeply furrowed, with broad, rounded ridges; while on all other American White Oaks (that is, Oaks which have the lobes of the leaves rounded without the slender bristles found on the leaves of the Black Oaks, and whose acorns ripen in one season), the bark is thin, light-colored, or, on some species, almost white, not furrowed, but separating into thin, flaky plates or scales.

Cultural Department.

New Chrysanthemums.

THE published lists of Chrysanthemums in recent years have contained the names of so many new varieties that the experience of any grower who has tried, so far as possible, all the new kinds, may be of some interest to those who are wise enough to limit their collections of this plant to the well-tested varieties. It has been possible for me, up to the present time, in a garden of moderate size, to try all the new foreign varieties and the larger part of those raised in this country. But the steadily diminishing number of really good novelties, and the pleasant lottery of raising seedlings, have convinced me that a more rigorous selection than that hitherto practiced must be henceforth made.

Lemoine, of Nancy, who publishes a list of the most desirable new varieties of Continental origin, gives the names of sixty-eight Chrysanthemums new in 1887. Cannell's list for the same year numbers fifty-seven; and the various American growers add at least fifty names to these.

Of the fifty-three Continental varieties of 1887, which I have tried, coming from such successful growers as Délaux, Lassali, Etienne Lacroix, Audiguier, De Reydellet and others, four only seem worth growing again; not that the rest are all bad, far from it, but they are either unsatisfactory in growth or not sufficiently distinct from existing kinds. The four selected are: (1) Lord Mayor (Délaux), styled in the introducer's description a large-flowered variety; the plant is of moderate size and a most profuse bearer of well-shaped, recurved, full flowers of white color, suffused with rose-violet. (2) Alcyon (Lacroix), a Japanese variety, with large flowers, the broad petals being rose-carmine, striped with white, and the centre of the petals a rose color. This variety is quite distinct from existing kinds, and is, moreover, of vigorous growth. (3) Louis Wicille (Audiguier) is a very early flowering Japanese kind, of good growth, well covered with large mauve-violet flowers, with a lighter centre. (4) Superbe flore (Lacroix), Japanese, appears to me the best recent introduction of its sort. It has very much of the habit of that always good variety, M. Délaux. The rose-carmine, globular flowers are borne on stiff, erect stems, and are somewhat lighter toward the centre; the petals are twisted, and white on the reverse side. It comes into flower early and remains fresh for many weeks.

Charles Delmas (Lassali), sent out as a large-flowered variety, is very like Robert Walcott in form and color, but does not appear to me equal to the latter. Mr. Cannell sent out in 1887 some varieties imported from Japan. Of these, Edwin Molyneux, Mr. H. Cannell and Mrs. H. Cannell are well worth growing. The first has broad petals, partially incurved, of the Mrs. Wheeler type—rich brown inside and yellow on the outside; the second, in the way of the well-known old variety, Grandiflorum, is of a rich, deep yellow; Mrs. Cannell is of rather dwarf growth, and has large, pure white, incurved petals. Ralph Brocklebank, a golden sport from the old variety, Meg Merrilies, has proved a very successful prize-winner in the English shows of this year, but did not do well with me. Avalanche, a pure white Japanese variety, also a great success this year in England, I have not grown and have not seen.

A number of importations in recent years direct from Japan has given our American growers an advantage which has been quickly improved. The new varieties are very distinct from those previously in cultivation, and their influence is already noticeable in a number of seedlings well worth preserving. Of an importation of Japanese Chrysanthemums, which flowered for the first time in this country in 1884, Mrs.

C. H. Wheeler, Hon. G. Welsh, H. Waterer, Gloriosum, Bicolor and Lord Byron may be especially noted, and are all worth growing.

The most remarkable Japanese collection sent to this country is undoubtedly that made by a Japanese named Neesima, for some time resident here, who, on his return home, sent to Mrs. Alpheus Hardy, of Boston, a small collection of Chrysanthemums. Among them was the now celebrated plant named Mrs. A. Hardy, which has created so much excitement at the flower shows of the past season. While to my mind this is cer-

larly good. No plant of 1887 has made so satisfactory an impression upon me, in my own houses, as Spaulding's John Thorpe, a Japanese flower of large size, rich, deep lake in color. Marvel, sent out by H. Waterer, a white Japanese with large violet blotch in the centre, is distinct and good. Mrs. Carnegie and Mrs. Morton, exhibited for the first time this year, are both striking and promising varieties, but should have another year's trial before they can be considered as fairly entitled to the positions now claimed for them.

Cambridge, Mass., December 4th, 1888.

H. P. Walcott.

Fig. 82.—Chrysanthemum, Lilian B. Bird.

tainly not the most beautiful Chrysanthemum in existence, it is probably the most valuable addition made in recent years to this class of plants. It is apparently of vigorous growth, a character sadly lacking in Mrs. Wheeler, Bicolor and others of this class, and should become the parent of many striking novelties. Some other flowers from plants belonging to Neesima's collection are also very good. The plants now in possession of E. Dykes & Son have not been themselves exhibited this season, but flowers from them have been shown, and these have been especially commended, and deservedly so. W. H. Lincoln, large yellow; Lilian B. Bird, large, full quilled pink flower; Kioto, large incurved yellow, are all particu-

Japanese Chrysanthemum, Lilian B. Bird.

THIS variety, an illustration of which, from a photograph, appears above, was received from Japan with the now famous Mrs. Alpheus Hardy. It is a flower of the largest size, with a full, high centre when at its best. Although it resembles somewhat in form the old Glorie Rayonnante in color, it is very distinct, being throughout of that clear and soft shade of pink commonly called "shrimp pink," a tint quite new to the Chrysanthemum. The florets are all tubular, or quilled, long and slender, with the ends scarcely expanded and slightly curved inward. The unique color,

large size and vigorous habit make this one of the most valuable of recent introduction.

Arthur H. Fewkes.

Newton Highlands, Mass.

The Vegetable Garden.

GLOBE ARTICHOKEs.—All gardeners know what uncertain plants these are. If one-fourth of those covered up in the fall are alive in the spring we should not complain, for these can be lifted and divided into as many pieces as there are well-rooted divisions, and all will be good flowering plants in summer. They will come in too early, however, for October flowers. For fall flowers seed should be sown now and the plants grown in the green-houses till next spring. There is no need of hurrying them, but if sown early and grown on moderately, they will be sure to flower next fall. If sown in spring and fed liberally, they often flower nicely in September and October, but this was not the case last summer, which was so cool and moist that few spring raised plants bloomed in the fall.

CELERIAC, OR TURNIP-ROOTED CELERY.—Although catalogued and sold by every seedsman, this vegetable is not often grown for use in private families, but it is grown in considerable quantity by the market-gardeners around New York and may be found in abundance just now in our city markets. The leaves are useless, the Turnip-like root being the edible part. Peeled and sliced they are used for flavoring soups and salads. The flavor is pronounced and agreeable, better than that of the self-blanching leaf Celeries and as strong as the red Celeries. It is very easily grown. The seed should be sown in April or May, the seedlings pricked off in June, and planted out in July or August in rich ground in rows fifteen to eighteen inches apart. It is often a disappointing crop, however, from a failure of the roots to reach a good size. Stored in moist sand, the roots may be kept in a cool cellar and in good condition for use all winter long.

SPINACH.—As soon as the ground is frozen hard a little hay, straw or thatch may be scattered over this crop to protect it from sunshine, sudden freezing and thawing and heaving up by freezing; but until the ground is frozen two or three inches deep, mulch should not be used on account of the field mice. Good Spinach can now be cut from cold-frames, if it was sown early in September, and if a light cover of thatch has been strewn over frames in hard, frosty weather. For an abundant crop, the Viroflay or Long Standing is preferable, but the market growers on Long Island grow the Savoy-leaved. Where a little protection can be given in winter, these varieties are as good as any other, but where grown in the open air, and without any protection, the prickly seeded is the best variety, as it is the hardiest.

UPLAND CRESS (*Barbarea*).—A good deal has been written about this plant as a culinary vegetable for the past two years, its use being urged as a salad and as a substitute for Spinach. After a fair trial, we do not find it any improvement upon the other vegetables we have and can grow easily enough. But as it is one of the easiest of all vegetables to grow, and forms large bunches of green leaves that remain in succulent condition all summer long, and as it does not run to flower the first year, it may serve a good purpose as a dry weather vegetable, or in localities where it is difficult to grow Spinach, Lettuces or Water Cress in summer. Nothing in our garden is as fresh and green to-day as a row of this Cress, and it was sown last April.

BRUSSELS SPROUTS.—These were never better than they are this year. Not only are the Sprouts abundant all along the stems, but they are close, solid, heavy and perfectly free from aphides. Generally they are so much infested with insects that many of them are not worth gathering, no matter how well they have grown. It may have been the copious and frequent rains during the fall months that have given us immunity from this pest. Of two sowings, one made May 23d, another June 26th, of Tall French and Dwarf Improved, both have done well, but with a slight advantage in favor of the May sowing. Brussels Sprouts are moderately hardy, but it is well to have them under cover before December. Deep frames, a cellar or a warm shed are good places for them. About the end of October I erected a temporary shelter for Chrysanthemums on the south side of a shed, using some spare sashes; on the 1st of December, as the flowers were about gone, the plants were cut down and removed and Brussels Sprouts planted in their place. In storing them in a place like this all the large leaves that grow on the stems should be stripped off, also the larger ones that grow around the top. When this is done the plants can be stored close together without danger of rotting.

Wm. Falconer.

Glen Cove, N. Y., Dec. 7th.

Rose Notes.

NIPHETOS.—Well grown flowers of this admirable variety are still sought for, and, under favorable conditions, it continues to rank as a useful and quite profitable Rose, though in many instances it has been supplanted by The Bride. Niphetos has been found to do very well on side benches, where the space above is somewhat limited, as its habit of growth is rather more spreading than upright. In fact, many of the flowering shoots are inclined to be pendent, the weight of the bud being too great for the slender shoots to support without bending.

The latter condition is rather a disadvantage at times, and may be corrected, in a measure, by budding this variety on some stronger growing plant. Excellent results have been obtained in some cases by using the Lamarque as a stock, the plants so treated having produced large crops of good buds for eight or ten years in succession. But where this system is adopted, and for such a length of time as that mentioned, the plants will naturally need more space than is afforded by the ordinary side bench. If grown on its own roots, it should be remembered that Niphetos is not a very strong rooting variety, and, therefore, is easily overwatered, and when once in that condition, it needs a long time to recover.

LA FRANCE.—This pioneer among the Hybrid Tea Roses has attained great popularity of late years as a valuable variety for all seasons of the year, its pleasing color and delightful fragrance being fully appreciated by the flower-loving public. It is also an excellent Rose for growing in pots, and has given a good return for the space occupied. The plants for this purpose should be struck in February or March and grown on until the autumn, when a short rest should be given to them, when they may be flowered during the following February. Much finer flowers are produced by this variety if the shoots are allowed to remain upright, and it is therefore best for it to be grown in such a situation as to render tying down unnecessary. Experience has shown that the flowers of La France should be allowed to develop almost completely before being cut, as the outer petals will often spread out to their full extent long before the centre ones are ready to open. If cut in that condition they frequently fail to open satisfactorily afterwards, and half their beauty is lost. This Rose is too often condemned, merely on account of the grower's impatience.

COMTESSE DE FRIGNEUSE.—This yellow Tea, of recent introduction, for which great things were promised, has thus far failed to realize, at least for commercial purposes, the expectations of those who have tested it. The color is pretty and it has a pleasant fragrance, but the flowers have but little size, and the plant itself is not very strong in growth, and thus it is found lacking in two very essential points. The glittering descriptions of new Roses, and the unqualified assertions as to their value made by some of their introducers before any adequate test of their merits has been made, must eventually prove an injury to this line of business. The notable failures of the past few years, such as Her Majesty, Princess Beatrice, and, with a majority of growers, Puritan also, has brought about a much more conservative temper on the part of the large Rose growers, and in future it is highly probable that many of them will test new varieties by the dozen instead of by the hundred. Experience with novelties in Roses has proved very costly in some cases.

Holmesburg, Pa.

Orchid Notes.

Cypripedium Spicerianum.—In the collection of Mr. De Witt Smith, of Lee, Mass., over 190 flowers of this handsome Lady-slipper Orchid are fully expanded, having dorsal sepals and lips of unusual size. Only within this last four years has this species been seen in quantity. Before that time it was exceedingly rare, having been introduced about the year 1878 by Mr. Spicer, of England, a great lover of this genus, in whose honor the plant was afterwards named. It is a free grower, enjoys a warm and moist position in the Cattleya-house, and should be placed in a compost of good turfy loam, peat and fresh sphagnum, ample drainage being very necessary. All the Cypripediums in this collection are well worth a visit to see, as they are perhaps the best grown in this country, and bid fair to equal any that are grown in Europe. Every plant is potted in sphagnum moss only; not a particle of peat or soil of any description is used. Mr. Norman, the gardener, is not satisfied with the holes put in the pots by the manufacturer, but manages by a skillful knock with a hammer to enlarge them to nearly twice their size. The visitor

can hardly help asking whether Mr. Norman does not use some liquid fertilizer, but that he denies emphatically.

Cymbidium Mastersi album.—Mr. John Wallace, of Paterson, New Jersey, has a plant in bloom in his collection of this somewhat rare variety. The flowers are born on a pendent stem having sepals, petals and lips of the purest white, the latter having a yellow crest, the purple spots as seen in the ordinary form being entirely absent. This plant inhabits the lower parts of the Khasia Hills, and luxuriates on old clumps of trees where from time to time decayed vegetable matter has collected. A Cattleya house temperature suits it admirably, and it enjoys a compost of decayed leaves, fibrous loam and an abundant supply of moisture while making its growth. During its period of rest it should be kept dry and somewhat cooler. Several plants of the chaste and scarce *Odontoglossum Harreanum* are flowering in this collection. This Orchid is sometimes called a yellow *O. Rossi*, but it is a supposed natural hybrid between *O. Rossi* and *O. cordatum*. Some of the flowers are of great size, and on one stout spike here the flowers were three and one-half inches across, with markings of a very rich color.

Improvement of North American Fruits.

To the Editor of GARDEN AND FOREST:

Sir.—We have cultivated for several years the wild Papaw (*Asimina triloba*), and it bears fruit regularly here every season. The fruit is delicious, and to my taste the best of the wild indigenous fruits of North America. Unfortunately, however, it contains too many seeds; these are large, and the amount of edible pulp is too small, therefore, in proportion to the size of the fruit, to make it really valuable. The Papaw, however, has not been improved by cultivation, and when it is remembered how the fruit-trees of Europe have been altered by long cultivation, and particularly by raising seedlings of good varieties, and by selection, I cannot help thinking that the same results may be secured by operating in this way with the Papaw. The result to be obtained is the establishment of a variety with a large amount of pulp in the fruit, and, if possible, without seeds. Such varieties are already known among grapes, pears, Japanese persimmons, oranges, bananas, etc. This improvement, if it can be effected, will make the Papaw a fruit of great commercial value, and it seems to be the duty of American pomologists and horticulturists to experiment in this direction. It would be necessary in the first place to select among the wild Papaws the varieties that seem to come nearest to the ideal standard, to grow seedlings from them, and then to select those seedlings which show the most improvement in the desired direction. If the experiments are continued long enough the ideal fruit will be developed, and then can be perpetuated by grafts. It will need, of course, some time to arrive at any result, but I am convinced that in three or four generations real progress can be made.

The Loquat (*Eriobotrya Japonica*) is now very well known in the south of France, but the variety which we grow is by no means the best. A Japanese agriculturist who has lately visited the Villa Thuret told me that a variety of Loquat exists in Japan with fruit three or four times as large as the one which we have. This variety, moreover, has only one seed, and not three or four, as in the common varieties. The size and number of its seeds is the only reason why the Loquat has remained such a third or fourth rate fruit, inferior even to the Medlar and Sorb (*Sorbus domestica*).

It surprises me that the *Sabal Palmetto*, which ought to be one of the hardiest Palms, has not, up to the present time, succeeded in the south of France or anywhere in southern Europe. Why? What is the influence in air or soil which prevents it from growing as well as many Palms do here?

The year 1888 has been the most abnormal known in Europe since the beginning of the century, and there has been no summer heat even in Algiers. The temperature in Provence has been three degrees centigrade lower than the average; and the result is that many exotics have not flowered this year, or have flowered so late that they will not perfect their fruit; and there are many failures with garden and field crops due to this lack of heat.

Charles Naudin.

Villa Thuret, Antibes, November, 1888.

[There are a few American fruits, as Monsieur Naudin points out in the case of the Papaw, capable probably or very great improvement. The Persimmon (*Diospyros Virginiana*), as well as the Papaw, is one of them, the fruit when fully ripe being considered by many persons, even now, delicious. It varies a great deal in quality, the fruit

from the extreme south being much less austere than that produced in the Middle States. It is sometimes entirely destitute of seeds, and of course these seedless varieties are the most valuable; and there seems to be no reason why the American Persimmon cannot in time be made to equal the Japanese varieties in size and flavor. There is no reason, too, why the American Chestnut cannot be as much altered and improved in time as the European variety has been; and the improvement of Hickory nuts, especially pecans, offers an excellent field for the American pomologist; nuts of all the Hickories show a great tendency to variability in size, shape and thickness of walls, but no special efforts have yet been made to take advantage of these variations with the idea of developing superior nuts. Sooner or later, however, this will be done. Pomologists have already shown what can be accomplished with our common eastern American plums, by intelligent selection and cross-fertilization, but no attempt, we believe, has yet been made to improve the common Plum of the Sierras, *Prunus subcordata*, a native of northern California and Oregon. The fruit is of very fair quality, although, of course, capable of improvement by the selection of seedling varieties. The Beach Plum, too (*P. maritima*), found upon the shores of the northern Atlantic seaboard, is another plant to which pomologists might, perhaps, direct attention with the hope of obtaining satisfactory results. A correspondent in Oregon calls attention to the size and beauty of a native Gooseberry (*Ribes Lobbii*), and suggests that it might, with a little care in selection, be developed into a valuable dessert fruit.—Ed.]

Recent Publications.

The Eulogy of Richard Jefferies. By Walter Besant. London: Chatto & Windus. 1888.

To those who love Nature and Nature's lovers, who have a sense for that mastery in the use of words which means high literary art, and who rejoice when one literary artist is commemorated by another, this life of Jefferies may well seem the most interesting book of the day. It would be too much to claim for Mr. Besant that he is an artist in words to the same degree, or even in the same sense, as Richard Jefferies was; but an artist he is, and he has never turned his talent to better account than he has in writing of the brother-in-arms whom he here commemorates. His book is a little pearl among biographies, and it will be a jewel of price indeed if it wins for Jefferies a wider place than he has hitherto held in the affections of the American public. Even in his own land he has had a somewhat limited, though enthusiastic, circle of admirers, but here his circle has been smaller still—because, perhaps, here he has had more rivals to compete with. Thoreau's name is the best which can be cited to explain—or rather, to suggest—the character of his writings; and Thoreau's followers have been more numerous in America than in England. Such articles as Jefferies wrote stood almost alone in English periodical literature; but on this side of the ocean work similar in kind (we do not speak of quality just now) comes steadily from a score of pens—work inspired by a keen love for all the minor as well as major beauties of Nature, instinct with true and delicate appreciation, and cast in a personal and artistic mould.

Richard Jefferies came of good yeoman stock, and was born in 1848 at Coate Farm, not far from Swindon, in Wiltshire. He was a studious boy, yet loved books scarcely so well as the great Book of Nature, lived much out-of-doors, and was taught by his father to use his eyes upon all he saw. A literary career early appealed to him, and at the age of eighteen he embarked in journalism, in connection with a Swindon paper, and almost at once began the writing of books as well. A pathetic time then ensued, when his novels went the round of London publishing houses, to come repeatedly back, as he said, "like the stone of Sisyphus." The first mark he made in the world was when, in 1872, he wrote a letter to the London *Times* on the condition of the agricultural laborer. This attracted great attention, was followed by three or four others, and Jefferies saw himself recognized as the chief authority in England on the agricultural questions of the day. But even then he did not realize that his true path was opening before him. For several years he still preferred to write novels of "high life" and adventure—things about which he knew nothing, rather than articles on country scenes and country people—

things about which no one knew so much as he. The novels were failures, however, while the articles succeeded, so he was gradually driven, we may almost say, to the work for which he had been born. Then for a number of years he was a constant contributor to various periodicals, and as fast as his essays accumulated they were republished in book form. Among his best known volumes are "The Game-keeper at Home," "The Amateur Poacher," "Wild Life in a Southern County," "Round about a Great Estate," "Nature Near London," "The Open Air" and "Hodge and His Masters." About seven years ago his health began to fail and was never restored before his death in 1887. During the greater part of this time he suffered incredibly, worn with want of nourishment and sleep, racked with perpetual terrible pain, and coming often under the surgeon's knife; tortured with poverty, too, wild with a longing for the out-door life he could no longer lead, eager to write but unable to hold a pen, external needs and internal cravings for expression tormenting the vigorous mind while the body was alive only in the sense of suffering. Yet during this time some of his most beautiful work was done—dictated bit by bit as his pain and feebleness allowed. One of his last essays was "An English Deer Park," recently published in the *Century Magazine*.

It is hard to explain the quality of Jefferies' work to those who do not know it. He kept a note-book, like Thoreau, from day to day, and if we may judge by the few extracts Mr. Besant gives, he seems therein Thoreau's inferior. The accuracy, the minute delicacy of observation, is the same, but the record is briefer and drier, and we miss Thoreau's poetical, philosophical tone. But in the essays which he published he stands on the same height as Thoreau in point of literary power—or, to many eyes, perhaps, on a still loftier height. His style is a marvel of ease, clearness, variety and charm, and as personal as a style well could be. It has certain oddities—as, for instance, the dropping out of the verb from time to time—which, with a weaker writer, we might resent. But everything Jefferies does seems right as he does it, for whatever it may be, it never means a lapse from graphic distinctness, from personal charm and grace and force. Then the human element, which is lacking with Thoreau, is very prominent with him—it is men in nature that he paints, not nature merely, or the soul of the single man who is gazing upon her. Very little definite instruction is to be gathered from his pages. He was even less a man of science than Thoreau, and nothing could be more naïve than his way of showing that he never thought of going to the most substantial sources of information for that knowledge of natural things which he earnestly desired to get. A "botanist friend," or a good book of colored pictures—these were the aids he sought, and while acknowledging their insufficiency, he felt no impulse to turn to the science of botany itself. And he never tries to tell us, as John Burroughs does, of all the lovely, interesting things we may find in this spot or in that. He simply records his impressions, now in the way of the most exquisite pictures of certain visible objects, and now in the way of thoughtful rhapsodies which are, perhaps, the finest things of their kind in the language—at once the sanest and the most ethereal, the most poetical and the most human. Sometimes his poetizing instincts lead him into work which can scarcely be called descriptive in any of its parts; sometimes an innate artistic instinct shows with curious distinctness, as when he refers to that method of painting which we call "impressionistic," which is so generally misunderstood and condemned by laymen, but which he felt to be true, in certain ways, above all other methods; and sometimes he is the social reformer, the prophet of the poor and suffering, the sympathetic man forgetting the beauty of inanimate nature, almost, in the sight of how men may struggle and perish on her bosom. The greatest charm of his work lies in its perpetual variety—but this fact makes it all the more impossible for us to do it justice within our narrow limits. It should be enough, however, to point our readers to Mr. Besant's biography. We can trust this to lead them straightway to Jefferies himself as his books explain him, showing us a man to admire and love, as well as a writer to enjoy and an interpreter of nature with a very personal and vital message on his lips.

Periodical Literature.

Scribner's Magazine for December appropriately opens with a beautiful article called "Winter in the Adirondacks," by Mr. H. W. Mabie. The text is pleasant reading, and shows true appreciation of the charms of winter landscape as well as of winter life in the wilderness. But the illustrations are of more exceptional value. Those from photographs are well

chosen and admirably executed; yet still better, because as true in their way and possessing the added charm of personal human feeling, are those from drawings by various artists. All are similar, of course, in theme; but this fact only makes their essential contrast more interesting. Six painters have seen the same themes under the same conditions; each has painted truthfully, but each gives us a different effect, because each has put a bit of himself into the result—has felt what he saw in a different way, and has clearly expressed his feeling. The picture by Mr. Crane, which was chosen for the frontispiece, is good, yet perhaps the least good of the six, while the charming "impression" by Mr. Twachtman, if not the very best, is at all events the most individual and charming. A single artist might have portrayed the aspect of the woods in winter as faithfully as it is portrayed in this article; but no one artist by himself could so thoroughly have portrayed their spirit, illustrated all their moods and meanings, and very certainly no camera could.

The fact that even the midwinter numbers of our great magazines are not thought complete without an out-door article of one sort or another, is a pleasing sign of the growth of our public in appreciation of nature. In *Harper's Magazine* for December, as well as in *Scribner's*, we find such an article—"A Midnight Ramble"—from the well-known pen of Mr. Hamilton Gibson. It is not so appropriate in theme to midwinter, we think for a moment, as the Adirondack chapter. But after a moment we are well content, for what can be pleasanter in midwinter than to find ourselves transported to midsummer—shown its loveliness and mystery in sympathetic words and charming pictures? Much as Mr. Gibson has written in former days about woodland rambles, he has found a new theme to-day. Taking us out-doors at midnight, he shows us many old friends with new faces—sleepy, drooping, dew-besprinkled faces, often very different from those the sun beholds. Much real instruction is prettily given in the text, which will tempt many readers to nocturnal explorations with a lantern. Yet, once again, the illustrations are still more attractive. The contrasted groups of Locust, Melilot, Lupine and Oxalis, here awake and there asleep, are particularly charming, while nothing could be more fairy-like than the sphinx-moths among the Honey-suckles, or more truthful and graceful than the Nasturtiums, and, especially, the Evening Primroses. He must be a happy man who can see so much in nature as Mr. Gibson, can write about it so well and can picture it so daintily. Most of us would be content with either one of his three gifts.

Meetings of Societies.

The Forestry Congress at Atlanta.

THE Forestry Meeting at Atlanta on December 5th, 6th and 7th, was marked by the termination of the existence of the southern organization and its union with the American Forestry Congress. The attendance at the meetings was large, and the people of Atlanta, the members of the Legislature, and the officers of the city and state governments, were constant and profuse in their courtesies to the visitors. There were pleasant receptions at the house of Governor Gordon and other places, there were very full and accurate reports in the leading newspapers, and the Congress and its objects and work received from everybody the most cordial and serious respect.

There were interesting essays and addresses by Colonel E. T. Ensign, on Colorado Forestry, and on Rocky Mountain Forests; by General Greely, on Rainfall; by Professor Charles Mohr, on Forest Lands; by Professor George F. Atkinson, on the Relations of Trees to Bird and Insect Life; by Mr. M. J. Kerns, on Public Parks and Forests; by Mrs. Ellen Call Long, on the Forest Features of Florida; by Professor Eggleston, on the Forestry Outlook; and the discussions were interesting, though they were restricted somewhat by the feeling that the tariff is an inflammable subject and one to be kept out of a Forestry Congress.

On the last day of the session there was a tree-planting at the Girls' High School, in the presence of vast throngs of people, with short addresses by members of the Congress. Officers were elected, committees appointed, and the customary resolutions adopted. There was nothing remarkable or striking in the proceedings, but the meeting was pleasant and interesting. The Congress represents very well the official side of forestry in this country, the ideas and work of the Forestry Division of the Department of Agriculture at Washington. Its vitality hitherto has, in great degree, been

the effect of Secretary Fernow's earnestness. He has now relinquished the Secretaryship, in order to have more time for his official work. It is likely that the next meeting of the Congress will be held in Philadelphia, if the people interested in forestry there so desire.

Notes.

From a note in *The Gardeners' Chronicle* of a recent date it appears that 2,300 varieties of Chrysanthemums are grown in the garden of the Royal Horticultural Society at Chiswick, near London.

The readership in botany in the University of Cambridge was last month conferred upon Mr. Francis Darwin, a son of Charles Darwin, in place of Mr. Vines, now professor of botany at Oxford.

At the exhibition lately held in Paris of fruits and appliances used in the manufacture of cider and perry, the first prize for a collection of cider-apples and the second prize for cider were carried off by English exhibitors.

At the second meeting of "L'Orchidienne" held at Brussels on November 11th, first-class certificates were awarded to *Cypripedium Harrisianum polychromum*, from Dr. Carnus; to *Ansellia Africana aurea*, from Madame Gibez; to *Oncidium Forbesii maximum*, from the Count of Bousies; to *Vanda carulea* and *Cypripedium callosum*, from Madame de Cannart d'Hamale; and to *Cypripedium nitens superbum*, from Mr. Pecters.

On a wall which divides the pleasure grounds from the kitchen garden at Warnham Court, a residence in the south of England, a fine specimen of *Magnolia grandiflora* has been trained so that it covers a space about eighty yards in length. A correspondent of a horticultural journal, describing it last summer, said the profusion of bloom was such that on one portion about a foot square he counted seven fully expanded flowers and several buds.

In some of the larger European botanical gardens—as, for example, the University garden in Berlin and the one in Heidelberg—the labels used for the trees are of zinc, with the name stamped in intaglio and then defined with oil paint. These labels are much cheaper than the porcelain ones, more commonly seen, and are equally durable, needing no care but the renewal, at long intervals, of the paint; and an additional advantage is found in the fact that they can be made on the spot by unskilled workmen.

Messrs. Tiffany & Co., of Union Square, in this city, have on exhibition a remarkable specimen of petrified wood from the fossil forest of Coriza, in Arizona Territory. It is the section of a large tree and measures thirty-six inches in height by forty and a half inches in greatest diameter. The character of the bark is well preserved, and the top, which has been carefully polished, is very beautiful in its agate-like colors, as well as interesting by reason of its clearly revealed markings. It is said to be the largest fossil specimen that has been thus prepared.

As this paper goes to press we learn that Senator Stanford has decided to devote to the Arboretum connected with the Leland Stanford, Jr., University, as much space as is needed to contain every tree that can be made to grow in that climate with the aid of irrigation. The trees are to be planted in open order, and arranged with vistas and views, so that the Arboretum will have the features of a pleasure-ground in addition to its scientific character. Mr. Olmsted is to make a design of the work and Mr. Thomas Douglas is to be superintendent of the planting.

The Largest Elm tree in Norway is supposed to be a specimen of *Ulmus montana* which stands in the parsonage grounds of the little town of Eker, a few miles from Christiania. When it was examined by Schuebeler in 1871, while he was preparing his *Viridarium norvegicum*, it measured seventy-five feet in height and six feet in diameter. *U. montana* is the only species of Elm which grows wild in Norway, and it never attains the dimensions of *U. campestris*, the species which produces most of the magnificent specimens found in Germany and England.

A Rose which flowers in the open ground in New England, after the middle of November, is a plant worth a place in any northern garden, even if its flowers do not possess the size or all the substance of some more modern varieties. Such a Rose is Hermosa, one of the Bourbon breed, which dates back as far as 1840. It is an abundant and constant bloomer throughout the summer and autumn; and there are not

many days during five or six months of the year, or until hard freezing checks vegetation, when flowers cannot be gathered from a well established plant. The flowers are pink and very fragrant. The plants, like most of the Bourbons, require some slight protection at the north.

In the horticultural papers of Germany frequent complaints are made that too little regard is paid to mere beauty by those who judge plants and reward their growers at public exhibitions. Novelty and singularity are too highly esteemed, it is said, and when the judge is a professional florist he is too apt to think exclusively of the plant's practical qualifications—to consider simply whether it is a strong and prolific grower and can be turned to practical account for commercial use. Of course these considerations must always be largely taken into account, but there is truth in the remark that pure beauty as such has likewise a right to recognition. Nor is the need that it should be more highly esteemed confined to Germany only.

The use of benzine has been found effectual in France in destroying the white grubs (the larvæ of the May or Dor Bug), which often do immense damage, especially in dry seasons, to lawns, Strawberry plants, seedling trees and other nursery stock. Holes are made in the ground infested with the grubs with one of the sharp iron dibles used sometimes in transplanting small plants, and the benzine is poured into them. Fifty grains of benzine are used to the square yard and care is taken to insert it above the plane of the feeding ground of the grubs. In an experiment recently made by one of the French forest officers, and reported at a meeting of the National Agricultural Society, the grubs on twelve acres were destroyed at a cost of only \$3.20 an acre.

The London papers report an interesting lawsuit lately won by Sander, the well-known Orchid grower of St. Albans, against the Duchess of Montrose, to recover the amount of his bill for plants and various services connected with fitting up the conservatories at Tifton Lodge, near Newmarket. One item of the bill was for 1,000 Orchids which were furnished at a guinea a plant, the seller being allowed to select what plants he chose. The interesting features of the whole case centred in the letters written by the Duchess's gardener to the manager of the St. Albans Nurseries, and produced during the trial. The tone of this correspondence, and the intimations which it contains, should make those persons who know something about their own gardens congratulate themselves that they are not entirely in the hands of their gardeners.

Attention is called in the European journals to the fact that *Magnolia Soulangeana*, one of the hybrids between *M. conspicua* and *M. purpurea*, bloomed this year in England during the month of September. The second blooming of this plant is not, however, an unusual occurrence in this country. A few flowers appear almost every year during August and September, and this year the trees were quite covered with them. The flowers are much smaller, however—scarcely half the size of those which appear in spring—and they do not expand fully. It is rather a curious fact that neither of the parents of this hybrid, or other hybrids of similar origin, notably *M. Norbertiana*, show any tendency to produce autumn flowers. The Japanese *M. stellata* has been known to flower in the autumn in this country, but not commonly or abundantly.

The Society of Amateur Photographers has recently held an exhibition of the work of its members at its rooms on Thirty-sixth Street, where welcome evidence was given of a growth in artistic feeling, as well as in the mere knowledge of photographic processes. Miss Catherine Weed Barnes sent some excellent rural views; Mrs. A. F. Arnold, a picture of Mangroves in Florida, which was really remarkable for good composition and effective portrayal of the trees, and Mr. David Williams, a large number of subjects most intelligently chosen. Lieutenant C. P. Howell contributed a series of small pictures taken in China, some of which were interesting, or, at least, very amusing, from a horticultural point of view. They represented figures, apparently of life size, in which only the heads and hands were visible, the other portions being thickly draped with growing vines. In one, a branch had been trained as a standard and passed through the outstretched hand of the figure to develop above it into an open umbrella. Of course one cannot call such oddities works of horticultural art, but it was certainly worth while to reproduce them for western eyes, as nothing could be more singular or more Chinese in effect—which means something very different from Japanese in effect—than a row of these figures, standing in large pots in the most grotesque and humorous attitudes, clothed in their rather ragged and prickly-looking vesture of vines.

A Botanic Garden for the City of New York.

THE daily papers have been discussing lately the possibility of establishing a botanic garden in this city. The movement certainly has not been made too soon. Botanical and zoological gardens form a part, and a very important part, of the educational equipment of a great metropolis; and it is not creditable to the people of this city that it is allowed to fall so far behind the other great commercial centres of the world in this respect. A thoroughly well-equipped and well-maintained garden, carried on upon the principles which should govern such an establishment, can exert a wonderful influence in developing and stimulating the intelligence of the public, not only by increasing the knowledge of plants and plant-geography, but of all that relates to horticulture and gardening.

A good garden, however, is not an easy thing to establish. It must be something more than a mere collection of growing plants; it cannot serve its purpose, indeed it cannot be administered, unless the living collections are supplemented by a herbarium and library, without which no garden is worthy of the name. A museum, too, in which the products of all plants can be grouped, while not essential for the administration of a garden, is an attractive and valuable educational feature, which should be provided for in any comprehensive scheme of this character.

There are two reasons why botanical gardens fail to accomplish what is expected of them, and why, from the point of view of popular instruction, there are so very few useful ones. Few persons realize what a very large sum of money it costs to found and maintain a great botanical establishment, and the gardens of the world which are adequately supported with proper endowments may be counted upon the fingers of one hand. The second reason why such gardens fail is found generally in the difficulty of securing men in whom scientific attainments are joined to great administrative capacity to manage them. The man who successfully conducts a botanical establishment, capable of influencing the intelligence of a great metropolitan population, must possess qualifications of the highest

order, and an enthusiasm for his work which will enable him to resist the temptations of more lucrative employment, and the opportunity of more immediate influence, which the attainments and character of such a man are pretty sure to bring to him. The gardens at Kew, near London, are what they are to-day—the finest botanical establishment in the world—not because they have been lavishly supported by the British government, but because, through circumstances unprecedentedly favorable, they have been controlled for three generations by men eminent in scientific attainment and administrative ability.

We call attention to these facts, not because we are not heartily in favor of the establishment of a botanical garden in this city, but in order that the people of New York may realize that it is no easy matter to secure a good one; that a good deal of money will be needed to support it; and that the proper man to direct the expenditure of this money must be something more than a good gardener or a successful florist, if the garden is to accomplish what is expected of it.

A garden, to be successful, like any other museum, must be disassociated entirely from politics in order to secure for it a continuation of management in the same hands. This is essential. The botanic garden of New York must be carried on without any reference to politics, and if this cannot be done the scheme had much better be abandoned at the outset. There is no need of any more botanical gardens in the world run for the purpose of supplying bouquets and dinner-table decorations for the politicians who control the appointment of the managers; or to serve as a means for advancing commercial or private interests.

The question of a site for a botanic garden in the city of New York presents some difficulties. There are certainly nowhere in the Central Park thirty or forty acres that can be spared for this purpose, or which are suitable for it. It has been urged that a garden in one of the new parks would be too remote from the great mass of population to be useful, but it would not be more remote from the centre of the city than the garden at Kew is from the centre of the London population, which, during some pleasant afternoons, is visited by more than a hundred thousand people. There is an advantage, too, in having the garden as far as possible from the dust and smoke of the city, which must in time influence Central Park unfavorably, and which is almost fatal to a good garden. It is probable, therefore, that if New York ever has a botanical garden at all proportionate to its size, it will have to be located in or in connection with one of the new parks, and whether such a garden is established in this century or not, a proper site should be provided for it in any scheme which may be adopted for their improvement.

There seems to be no reason now why such a garden might not be carried on under the control of a board of managers, in the same way that the Museums of Art and Natural History are controlled, or by the trustees of Columbia College, either independently or forming part of a larger board. Columbia College already owns a very large and valuable herbarium, and a very considerable botanical library. These, in order to avoid duplication, might very suitably serve as a nucleus for the new establishment. The Museum of Natural History contains a special collection, the magnificent gift of a public-spirited citizen of this town, which might well be the foundation of the new museum, and which would give to it at once a character possessed by no other botanical museum in the world.

But what the situation requires, if the desire for a botanical garden really exists in this community, is that some man of wealth, influence and public spirit, fully alive to the importance of making New York a metropolitan city in the truest sense, should appear and gather together the material already available, raise the funds necessary for the establishment, and secure from the city a suitable location, and such co-operation as may be necessary. When this has been done, and the man who can organize and carry on

such a garden has been secured—and the demand will sooner or later find or develop him—New York will have a botanical establishment worthy of its intelligence and wealth, which will instruct and enlighten its people and make its influence felt for good from one end of the land to the other. The man or men who can accomplish this will, we believe, be as worthy of the honor and gratitude of the citizens of New York as any who have given their time and money for its improvement and advancement.

Fruit and Vegetables under Glass.

A SCORE of years ago fresh fruit and vegetables grown under glass were hardly to be found in any abundance or variety in the winter markets of our great cities. Enterprising gardeners there were in private places who were ambitious to prove their skill by furnishing home-grown Asparagus and Green Peas for the Christmas dinner; but unseasonable delicacies of this sort rarely, if ever, found their way to consumers from commercial growers through the ordinary channels of trade. It is true still that many of the choice grapes, nectarines, peaches and strawberries for city tables come from green-houses that are not strictly commercial. It often happens that in private places fruit and vegetables are produced in excess of the family needs, and the surplus is sold to the city dealer. But, aside from this somewhat irregular traffic, the growing of winter fruit and vegetables of nearly every variety for market has become an important industry, and a rapidly growing one in spite of the fact that facilities for transporting perishable products from warmer climates are multiplying and improving every year.

Cold-frames and pits which were originally used to lengthen out the season in autumn and hasten the coming of spring, were very naturally succeeded by cool houses, which offered every advantage given by the frames, with much greater convenience. But an apparatus for heating such houses will not alone suffice to insure a crop of winter vegetables. Special experience and skill are required if any profit is realized, for one may be an expert in growing Tomatoes, for example, out-of-doors, and still be unable to persuade his plants under changed conditions to set any fruit. For a month past hot-house tomatoes have been in strong demand here at sixty cents a pound, wholesale, and this is not an uncommon price. They have sold in this city at a dollar a pound when tomatoes fresh from Havana were bringing seventy-five cents a peck. This means that hot-house tomatoes have a genuine value, which comes from superior quality—for this difference in price cannot be entirely due to a mere fancy—and that the skill to grow them well is not generally possessed by market-gardeners—or they would be more abundant. The best growers now can produce beautifully colored, well-flavored, and solid, ripe tomatoes for winter marketing within three months from the day the seed is sown. To accomplish this, varieties specially adapted to culture under glass have been originated, with size and habit of growth that insure the greatest amount of fruit in a given space—that is, with a given amount of fuel. Expedients have been devised for insuring fertilization so that the plants may set fruit well down to the ground. In short, the needs of the plant under artificial conditions have been so thoroughly studied, that a good winter crop of tomatoes can be looked for with greater certainty than can a good field-crop in the summer.

But even when all this special knowledge becomes common property, and when competition is sharpened by a growing demand, choice fruits and vegetables out of their season will continue to be classed among luxuries. There are other crops which require even greater skill for profitable production than the tomato. This is especially true of some of the tree-fruits which necessarily occupy a large space and are most exacting in their demands for special attention throughout the entire year. Some of them at flowering time even show a preference for a particular

kind of insect to help them in the distribution of their pollen. Peaches and nectarines at six dollars a dozen, grapes at five dollars a pound, with strawberries at five dollars a basket (and very diminutive baskets have been selling at that rate on Broadway within a week), are expensive articles of food, but, from the grower's point of view, these prices are not exorbitant at certain seasons of the year. And a vegetable as easy to force as asparagus may well command two dollars or more a bunch, because the plants must be cared for three or four years before they are strong enough to produce shoots of proper size, and after one season's use under glass they are practically worthless. Mushrooms at a dollar and a half a pound, green peas at a dollar for a scant pint when shelled, snap-beans worth enough to be sold by a count of the pods, are paying crops only when carefully grown. Even at these high prices, every foot of space must be employed, with a crop of one kind coming on between the rows of another as it becomes fit to market, and with a plant ready always to occupy every place made vacant by the removal of another. One grower in Jersey City, who has 25,000 square feet of glass devoted to Radishes alone, and who is prepared to deliver 12,000 bunches a week, considers it an unsuccessful season when he cannot market five crops between the 20th of September and spring weather.

A few years ago these expensive fruits and vegetables were found only in the shops of a few retail dealers in fancy fruits, but now the call for these products has so increased, that nearly every variety of garden-fruit and vegetables can be found among the regular consignments to wholesale dealers. And it may be added, that certain other fruits and vegetables can rarely be found here, except when grown under glass. The long cucumbers, so highly prized by some people, will only develop to advantage when an almost tropical climate is provided for them. Certain varieties of European strawberries, with a flavor greatly relished, are among the best for forcing, although they refuse to flourish in our gardens. It is well known that the varieties of Potato most highly prized in England will come to nothing here under out-door cultivation, and an enterprising marketman near this city has now growing in his green-house some Ash-leaf and Walnut-leaf Kidneys, in the hope that some one will pay him a dollar a pound for his tubers, on account of their supposed nutty flavor, or because they are strictly English.

After all, imagination may help to give an inflated value to these fruits out of season, and families of moderate means need not lack for wholesome and toothsome vegetables at any season, thanks to cold storage, quick transportation and approved methods of preserving. And there are old-fashioned people who entertain the very old-fashioned idea that no fruit or vegetable is ever really pleasing to the taste except in its proper season.

Christmas in the Pines.

THE Holly and Mistletoe naturally take the first place as decorative plants at Christmas time, as they have been from time immemorial identified with this festival; and at this season the Holly's "armed and varnished leaves" and clusters of bright red fruit are at their best, and so are the clear white waxen berries of the Mistletoe interspersed among its thick pale-green leaves.

But there are many other charming plants to be found in the Pines that can be used with even better effect than these. The Laurel is much more easy to handle than the Holly, and its glossy green leaves are quite as beautiful, and they can be lighted up with clusters of the bright scarlet berries of the Black Alder, which can be found in abundance in the damp barrens. The large, thick, shining leaves of *Magnolia glauca* can also be put to effective use with other foliage where extensive decoration is required. The deliciously fragrant Wax Myrtle should not be neglected. The glossy leaves as well as the thick clusters of pearl-gray fruit make it one of the very best plants to group among the scarlets of the Holly and Alder.

Some of the smaller shrubs, too, are now invested with a rare beauty which seems more striking since the foliage of so many of their neighbors has faded and fallen; and this is

especially true of the little *Leiophyllum*, whose small shining leaves are clustered thickly at the ends of its branches; while among the larger trees the Cedars and Pines have more to offer than boughs of dark green foliage. The bright gray fruit of the one and the symmetrical cones of the other are invaluable for giving character to decorative work.

Where heavy massing is not desired, evergreen vines like *Smilax Walteri* have a grace that is unrivaled, although it requires some resolution to penetrate the thickets where it hangs out its clusters of coral-colored fruit. The common Green-brier (*S. rotundifolia*) is also beautiful now, being evergreen here, abundant and loaded with blue-black berries. The trailing stems, evergreen leaves and brilliant fruit of the larger Cranberry (*Vaccinium macrocarpum*) are not to be neglected. The running Swamp Blackberry has been mentioned before in these notes, but the delicate veining and exquisite color of the leaves upon the slender and flexible vine when hanging in festoons against a light background seem the perfection of dainty grace.

The aromatic Wintergreen is also here in the greatest profusion, and its leaves have now taken on various colors which harmonize well with the cheerful red of its berries. The Prince's Pine (*Chimaphila umbellata* and *C. maculata*) are among the very best of the smaller plants for decoration, especially the latter, the leaves of which are variegated with white, while at Christmas time a rosy tinge is added. Nothing can be more beautiful than groups of these little plants mixed with the deep-green Laurel.

Several species of Club-moss (*Lycopodium*) grow in the Pines, and these can always be used to good advantage. Their flexible stems are easily managed, and their foliage retains its fresh look for a long time.

Groups of dry seed-pods are also effective scattered here and there among the evergreens. The pretty urn-shaped seed vessels of the Meadow Beauty (*Rhexia Virginica*), with many others that may suit the fancy, are now found in plenty. Surely the Pines offer abundant material for Christmas decoration, but the beauty and grace with which the Pines themselves are adorned is indescribable.

Mary Treat.

Vineland, N. J.

Florida Oranges.

THE present orange crop in Florida is twice as large as the last, and it is a matter of no little solicitude, with all who are interested in orange growing, to know how the markets will bear the additional strain. The last crop sold at satisfactory prices, many northern dealers coming to Florida to buy the fruit, both in the groves and in the auction market at Jacksonville. A home market is the ideal of the orange growers, but it is not likely to become permanent, because the producers will not unite on any one plan of action, but persist in sending their fruit, each for himself, to hundreds of commission houses in the north and west, so that buyers stand the best chance of getting fruit cheap by staying at home. Shippers, as a rule, expect much better returns than they receive under the commission system. Dealers who solicit fruit to sell on commission are prone to hold out flattering inducements, which are too readily believed, while those who come to buy on the ground have to pursue the reverse policy, since they assume all the risks, while the commission merchant throws all the risks on the shipper.

None realize the evils of the commission system better than the Florida orange growers; yet nearly all of them continue to dispose of their fruit in this manner year after year, simply because they will not unite upon some one definite plan of action, by which they might prevent gluts at centres of distribution and needless depreciation in prices. What is still more important, a wider and more equitable distribution of fruit could thus be brought about, which is the only effectual way of counteracting the effects of overproduction. There would be no cause for present apprehension on this score if the product of the Florida growers could be marketed in summer, but, unfortunately, it is in its prime in Winter. In November the fruit is not strictly marketable. If left on the trees till spring much waste results, and in the counties north of Orange Lake there is about one chance in three of losing the entire crop by frost. No reliable means of preserving the fruit fresh, after it has been picked from the trees, is known, except by cold storage, which is probably too expensive, and when taken out of cold storage houses fruit is said to go down quite rapidly. Californian Oranges have the advantage of being late in ripening, not being marketable until spring. It seems advisable that late varieties should be sought for and largely planted in southern Florida.

At present a movement is on foot to open up European markets for Florida oranges. Considerable fruit was sent to England last winter, and the returns were quite satisfactory. This season a company in New York has taken up the business of shipping Florida Oranges to Europe, and the results will be watched with much interest. It appears that Mediterranean fruit does not come into market before January, and hence, that there may be good demand for Florida fruit through December, and perhaps later. The danger to be apprehended is that much immature fruit, shipped in November, may create a prejudice at the outstart which will be damaging. This evil is experienced every year in the American market, as a result of picking fruit before it has acquired proper color and flavor, even as early as in October. Despite persistent warnings through the Florida papers, many persons will begin shipping as soon as the yellow hue makes its appearance on the fruit. It sells well for a few weeks, till the public has had a taste of the fruit, and then comes a reaction, from the effects of which the market does not recover before Christmas week.

Many advocate the selling of Florida oranges by auction in northern cities, while some oppose it. This system has been pretty well tested, but the average returns have not differed materially from those received from commission merchants; so the latter may be said to remain masters of the situation. It should be observed that the leading orange growers, who have established a reputation for their fruit and have selected reliable agents to sell it, have a great advantage over others and realize much more satisfactory returns. Orange growers of this class can hardly be induced to join themselves to any general organization, and this fact is, perhaps, the greatest impediment to any effort at combination. Those who are naturally looked to for leadership will not respond, and a co-operative movement that lacks their indorsement is looked upon with distrust. It will be seen that there is something lacking to make orange growing all that fancy has painted it, and that while the lack may be supplied, it is much easier to prescribe the remedy than to apply it. Possibly something may be evolved from the experience of the present season which will tend to advance the industry in the estimation of those who would not follow it merely from æsthetic considerations.

Foreign Correspondence.

London Letter.

FOLLOWING on a summer which was remarkable for the absence of sunshine and heat, we are experiencing a November of exceptional warmth and openness. Primroses, the harbingers of spring, are flowering in the hedge-rows and copses almost as freely as if it were March; Violets are equally abundant; while the hardy Cyclamens, Christmas Roses, winter Heliotrope, and many other plants which usually sleep hard till January, are in full bloom. Not only the flowers, but also the birds, are deceived by the weather, and thrushes sing as lustily as if it were pairing time. Many deciduous trees and shrubs still retain their foliage; bedding plants, such as Verbenas, are still healthy and flowering. Truly this has been a very mixed year in regard to weather.

Primula capitata is the sweetest herbaceous plant now in flower. Its normal flowering time is May or June, but it appears to have been affected by the weather in the same way as the common Primrose. As a plant for an unheated greenhouse it occupies a foremost place here. I have a bunch of its purple, compact heads of flowers before me as I write, and their powerful odor, Hawthorn-like, fills the whole room. Some of the heads are fully two inches across and contain about a hundred blooms and buds, the latter, occupying the centre, and covered with white meal. The stalks are nine inches high, rising from the centre of a tuft of healthy foliage, not unlike that of *P. vulgaris*. It is Himalayan, and comes freely from seed. The pretty, white Zephyr flower (*Zephyranthes candida*) is in full blossom in a sunny border out-of-doors. It is the only species that is happy in the open border in the neighborhood of London. The other kinds, especially *Z. carinata*, are in great favor here as summer-flowering greenhouse plants.

Cyrtanthus lutescens and *C. Mackenii*, although not the brightest in color nor largest in flower, have proved much the most useful of the dozen or so species which have been cultivated here at one time or other. The genus is one of the hardest of the Cape genera of bulbs to grow successfully in Europe; but the above are exceptions, as, for the last two years, they have grown and flowered most freely at Kew

under very simple treatment. They are scarcely ever out of bloom, and just now they are unusually good, which is a point greatly in their favor when considering their claims as garden plants. *C. lutescens* has leaves a foot long, half an inch broad, green and fleshy; the scapes are a foot long, each bearing an umbel of from six to nine flowers of a soft lemon-yellow color which are one and a half inches long, narrow tubular, the six short segments reflexed, the stamens as long as the tube, the style a little longer. Each flower keeps fresh over a month, so that for bouquet, and like purposes, they would prove of great value. *C. Mackenii* is similar, but pure white, the tube slightly bent, and the segments not reflexed; the flowers measure nearly one inch across. In a cool green-house, with the same treatment as suits *Vallota*, these two plants are certain to prove successful.

Hippeastrum aulicum.—Everybody is looking after the new and flashy hybrid *Amaryllises*, but no one appears to care for the species. And yet some of them are first-rate flowering plants, with plenty of color attractions. Such a one is the above, and when one recollects that this and *H. reticulatum* are the only two which bloom before Christmas, its claims as a garden plant are undoubted. There are some fine examples of it in bloom at Kew now. They have plenty of full sized foliage (another good point), the scapes are stout, nearly two feet high, and bear each two flowers, six inches long and six inches across, of a deep crimson color, with darker shadings, and a green star at the base inside. The flowers have been open a fortnight and are still good.

Orchids.—We have as many named varieties of *Lælia anceps* as of *Cattleya Mossia*, and some of them are as much alike as two peas. There are good, well-marked varieties, also, and we do not seem to have reached the end of them yet, for the Orchid of the week is a very beautiful and distinct variety of *L. anceps* which has flowered with Mr. Sander at St. Albans, and which he has named *Amesiana*, after Mr. Ames, of North Easton, Massachusetts. The width of the flower is four inches; the sepals, one-half inch broad, narrowed to a long point; the petals, one and one-half inches broad, also long-pointed; both sepals and petals are ivory-white, tipped with rose-purple. The labellum is smaller than in the type, the lateral lobes are incurved, white, with lines of red inside, the front lobe small, narrowed almost to a stalk at the base, and colored rich maroon-purple. There is also a very prominent ridge-like crest running from the front lobe into the throat which is colored bright yellow. This variety is considered the equal in beauty of *L. anceps Dawsoni*. Its value is shown by the price paid for it by Mr. Sander—200 guineas—although, in 1883, this same plant was purchased from Mr. Sander for two guineas; but it had not then flowered. Another addition to the list of sensational Orchids, *Odontoglossum Schræderianum*, is also in flower in the St. Albans nursery. It is an unusually stately plant, standing between two widely distinct species, *O. Karwinski* and *O. laeve*. It resembles both in growth and has a long paniculate inflorescence; each flower measures three inches across, the sepals and petals are one and one-quarter inches long, one-half an inch wide, pointed, spreading, the three upper ones curved upwards, the two lower curved down and inwards; they are colored yellowish-white, with large and numerous blotches of purple. The lip is pandurate, an inch long, nearly as broad, the basal half a bright crimson, the apical half pure white. It is a remarkable and handsome species, certain to become a popular Orchid for the cool house. It was introduced and flowered in 1887.

Odontoglossum Harryanum has bounded into the very front rank of Orchids. It is a most delightful plant, full of charming variety, quaint and attractive in form, fantastically yet richly colored, and, withal, as easily grown as *O. crispum*, and almost as cheap. A good garden plant ought always to be abundant and cheap. The plant of *O. Harryanum* which first flowered had but two blooms, and those not of the best, yet they made the eyes of Professor Reichenbach twinkle with delight when he saw them (he was staying at Kew at the time). But we have now spikes with eight, nine and eleven flowers, and collectors say there are even more. A fine variety with eleven flowers on the spike is now in bloom at Kew.

Masdevallias are general favorites in England, even the small "botanical" species finding many admirers. At Kew we have over eighty species, about a dozen of which are in flower now. Three of the most remarkable are, *M. macrura*, a large-flowered, long-tailed species, the sepals united at the base and forming a shallow cup, one inch across, and then separating into three narrow tails six inches long. Inside there are lines and warts of a purplish color, the rest of the flower being yellowish green; the petals and lip are very

diminutive. The leaves are one foot long, two inches across, thick and leathery. The peduncle is as long as the leaves. *M. Mooreana* is another large flowered kind belonging to the *Peristeria* and *Coriacea* group. The sepals form a cup one inch across, with a prominent chin; they then separate into three projecting tails three inches long, the lower ones united by their inner edge and then turned outwards; these are purple, the upper one being yellow with purple lines. The lip is large, tongue-shaped, and colored dark purple. Leaves are six inches long, one and one-quarter inches wide, thick, fleshy, and very dark green. The last of the trio is *M. pulvinaris*. It is a very singular species, quite distinct from any other cultivated *Masdevallia*. The scape is one and one-half feet high, purple, clothed with close-fitting bracts and covered with a whitish scabridity, rough as sandpaper, but slightly glutinous. The flowers are produced on the upper six inches of the scape, about a dozen on each scape. They are an inch apart, and each one is an inch long, reversed, so that the labellum is uppermost; the two upper sepals are united and form a boat-shaped hood. Inside they bear two oblong, fleshy, yellow, cushion-like processes, the object of which is not clear; the lower sepal is concave and as long as the upper ones. Color purple and dull yellow. Botanically, this Orchid is the most interesting plant now in flower at Kew, but its lack of bright color will prevent it from ever becoming a popular garden plant.

Cattleya Gaskelliana is worth growing as a market plant, or, at all events, for the sake of its flowers, which are deliciously fragrant, beautiful in form and color, very freely produced, and at their best in October and November. In Messrs. Low & Co.'s Nursery at Clapton there are many thousands of this Orchid, occupying a very large house, and from them bushels of bloom have been cut and marketed this autumn. The species is very easily managed, as easily as *C. Mossia*.

Disa racemosa.—There are only two good garden Disas, namely, the superb old *D. grandiflora*, of which every garden possesses, or should possess, dozens, and *D. racemosa*. This is a recent introduction, but it bids fair to become a popular Orchid. It is easily grown, requiring the same treatment as *D. grandiflora*, and blooms abundantly in spring. Each growth produces one or two tall spikes, each bearing from six to twelve deep-rose flowers, which last three or four weeks. It is a native of the east side of the Cape.

Vanda Amesiana is a delightful plant, of which little is known yet, but quite enough to satisfy one that it will prove a first-class garden Orchid. It was introduced and flowered by Messrs. Low & Co. in 1887, and a second imported one in excellent health has recently arrived. The narrow fleshy leaves are six inches long, the erect crowded spike of flowers, each one and one-half inches across, with pure white sepals and petals, and a large rosy-red lip; these give this species a character distinct among *Vandas*. It is also easily grown if placed in the same house with *Phalænopsis*.

New or Little Known Plants.

Syringa villosa.

AN account of this beautiful Lilac, of which an illustration appears upon the opposite page, was published upon page 222 of this journal. It is a native of northern China, and the plant from which our illustration was made was raised in the Arnold Arboretum from seed sent from Pekin by Dr. Bretschneider. *Syringa villosa* is a vigorous and very hardy shrub, now five feet high here, by as much through the branches, with stout, erect, pale brown shoots, marked with white spots, broad and ample pale green strongly reticulate-veined leaves, and narrow, and rather obtuse, often interrupted clusters of pale rose or flesh-colored flowers, which are decidedly less fragrant than those of the common Lilac. They appear here towards the end of May.

S. villosa is a valuable and desirable addition to gardens. The only drawback which it has yet developed as an ornamental plant is found in the fact that its leaves fall very early, or after the first frost, without any change of color.

Our plant seems identical with the one recently figured in the *Revue Horticole* (November 1st) under the name *Syringa Emodi rosea*, which has flowered in the *Jardin des Plantes*, in Paris, and was raised from seed sent also by Dr. Bretschneider. As was pointed out in the description already referred to, the *S. Emodi* of the Himalaya, in spite

of slight differences of habit and of the form of the leaves. is probably not distinct from the north China plant, so that the name *S. Emodi* should, if this view is adopted, disappear in the older name of *S. villosa*.

C. S. S.

these two apples, the German being altogether superior to the Russian. Yet it is a fact that there is scarcely any difference in their market price. I have been interested in following the market quotations, and find

that only for shipping to England does the Gravenstein lead, and this mostly when grown in Maine. The Maine Gravensteins are so much superior in keeping quality that they may be almost rated as early winter apples. Close to the Gravenstein in popularity with buyers comes the Porter, but this is an apple that bruises so easily, and is injured so greatly by bruising, that it can only be grown profitably for a near market. The Gravenstein was brought into New England from Belgium early in this century, and first propagated in Byfield, Massachusetts. No foreign apple ever achieved a more rapid or better deserved popularity in America. It is one of the very few fall apples of good size, fine appearance and high quality, that can be handled, kept and transported without injury. These merits have given it a position alongside the Hubbardston in the Boston market. Yet there are many other fall apples grown and highly valued for home use. High among these is the Mother, which ripens in October, though its season extends up to and beyond the holidays. Truly, as Cole says, "The Mother has no superior, and very few equals." Yet it is rarely on the street stands, and is hardly known except among old New England families of rural origin or affiliations. The Gravenstein and Hubbardston have gained the lead upon the Mother as a market fruit, notwithstanding its good size, handsome appearance and surpassing quality. Perhaps the chief reason for this is that the Mother, as Downing notes, is "rather too tender for shipment." This apple originated in Bolton, Massachusetts. Next to the Mother comes the Garden Royal (native of Sudbury, Massachusetts), of which Cole says truly, "Nothing is superior," though he adds, "rather small for market." Yet we find it, with Mother, in the best fruit stores, patronized by the old families, and in the gardens of many farmers, though usually but a single tree. It is produced in great perfection about Portland, Maine, and there I have seen it on the stands oftener than in Boston. Garden Royal is about the size, form and color of Fameuse, yet they are easily distinguished by the eye.

The Fameuse is a standard variety in the Boston market, where it goes by the name of "Snow." Being a good shipper, it comes from many directions, and is everywhere for sale about Thanksgiving time. It is grown up to the northern limits of New

England, where its season extends to and beyond New Year's day. It is a handsome, delicate apple, with a delicate, peculiar flavor, everywhere recognized and liked, though it is by no means a rich or aromatic apple. The tree is hardy and productive, but the fruit is liable to spot in unfavorable seasons and localities, sometimes to the extent of making the whole crop unmerchandiseable. This apple is popular, and as commonly grown in Connecticut and Rhode

Fig. 83.—*Syringa villosa*.—See page 520.

Cultural Department.

Autumn Apples in New England.

AMONG the autumn apples, the Gravenstein is now decidedly taking the lead throughout the southern half of New England, as the Duchess of Oldenburgh does in the northern half. There is no comparison between the dessert quality of

Island as elsewhere in New England, but the best and fairest fruit comes from the Champlain valley and islands. The Fameuse is of Canadian origin, and Canada has produced a vast number of seedlings from it, some of which, though little known, surpass it in many points. These seedlings are now being made better known, and somewhat disseminated, through the efforts of the Montreal Horticultural Society.

Connecticut's best contribution to our list of fall dessert apples is the Mexico, which is pretty well distributed in the east, yet not largely grown for market. This is a small red apple, much in the style of Fameuse, with tender flesh and a fine, high flavor. Origin, Canterbury, Connecticut.

In New Hampshire Jewett's Fine Red (Nodhead) takes the lead as a fall apple everywhere, both for home use and market. Like the Fameuse, it can be kept into the winter, but does not long retain its remarkably fine, delicious, aromatic flavor. This apple is also well distributed in southern Maine and Vermont. Origin, Hollis, New Hampshire.

The Winthrop Greening is a native fall apple, held in very high esteem in western Maine. It is large, golden yellow, with slight russet and a tinge of red in the sun. This apple has a tender, crisp, and very juicy flesh, with a sprightly, luscious flavor, mildly tart. Its reputation seems to be strictly local.

But the great native fall apple of southern New England (extending somewhat into the winter along the northern range) is unquestionably the Hubbardston Nonesuch, of Massachusetts. Truly does Downing declare that this Apple is worthy of extended culture; and it has attained it. The Hubbardston is found in nearly every orchard in southern New England, but unfortunately its northward range is not so wide as we could wish. It is a failure in most parts of Vermont and New Hampshire, and succeeds only in south-western Maine. A fine, large, roundish, oval apple, striped and splashed with two shades of red, with yellow, juicy, tender flesh, mingling sweetness with sprightly acidity, it is well entitled to class with the best, in our lists. It also has the qualities needed for a great market apple, the tree being vigorous and productive, and the fruit firm enough for transportation.

In northern New England the Duchess of Oldenburgh is planted everywhere, and produces fruit superior in size, beauty and quality to the same variety grown further south. Yet there is only a day or two in its existence when it can be classed as even a tolerably good eating apple. With cold storage it can be kept till Christmas, and this long-kept fruit, losing no beauty, gains considerably in quality, so that it brings good prices.

A favorite fall apple in the cold north-west, for home use, is the Peach of Montreal. This variety is worthless for shipping, as it will not improve if prematurely gathered, while if allowed to mature on the tree it bruises with the slightest touch. The tree is vigorous and productive, and the fruit one of the most beautiful grown, having a creamy skin with a lovely pink blush in the sun. The size is medium to large, form conical, flesh white, delicate, very soft, juicy, subacid, and pleasant in flavor, without much aroma or distinctive taste.

Lyman's Pumpkin Sweet is, I think, the most widely grown and popular among the Fall Apples of this class. The tree is vigorous and productive, and the fruit is especially fine for baking.

T. H. Hoskins.

Newport, Vt.

A Garden of Chrysanthemums.

A NOVEMBER garden, even if filled with the most obscure flowers, would make a very satisfactory ending of the out-door season; but the illustration on the opposite page, from a photograph taken in late November, dimly sets forth what even a small garden can show at that season in the way of Chrysanthemums, which certainly have no rivals among autumn flowers.

Those shown at the side of the house (with the exception of a few pots useful for filling vacancies) are grown where they bloom, and at approach of frosty weather are protected by cold-frame sashes resting on temporary framework. If the weather is very severe, a canvas curtain is dropped in front, and the window of a warm cellar in the rear is opened to temper the air. If kept dry, plants in such a position are seldom injured, in this latitude, before their blooming time is naturally over. The main portion of my collection, some 250 plants, is, however, more thoroughly protected from frost and winds by the tent shown on the right of the picture. This has a ground area of twenty by thirty feet, with fourteen feet ridge, two masts and six feet walls. It is made of sail-duck

and is strongly roped. It is easily raised over the plat by five men in as many minutes when the usual early October frost threatens. The walls are cleft up in pleasant weather, and the plants have as cool treatment as is consistent with safety. The heat is supplied by a Hitchings Base Burner located in the cellar, with a two-inch wrought iron flow and return pipe running around inside the lower base of the walls. With this arrangement the plants passed through two nights this season, with an outside temperature of 20° Fahrenheit, uninjured, and much sharper weather would probably injure none but a few in the centre of the plat. I cannot see that the light in the tent is prejudicial to the coloring of the flowers. The walls are up every fine warm day, and the flowers have a certain amount of strong light in any case. If any flowers are affected they are the pinks, which perhaps come a little lighter in the centre of the tent. Ventilation is somewhat self-regulating, as the wall hooks on the roof under a curtain, leaving open spaces which have to be pinned up when the weather becomes severe.

It is no great trouble to grow Chrysanthemum plants, and I have no general cultural theories to explain. I leave home at eight o'clock in the morning and return at seven in the evening, I keep no gardener, and yet find no difficulty in caring for 400 Chrysanthemums, besides a considerable collection of hardy perennials and other garden plants. My purpose is to grow a large crop of good flowers with the smallest outlay of money and labor.

My practice is to plant out the slips (with a strong stake to each) as early in May as possible, in double rows, say eighteen inches apart each way, with a thirty-inch space between the double rows. For my very heavy soil a liberal supply of horse-manure and bone-dust under each plant affords the needed nutriment. The plants are in no way coddled at any stage, the care being about the same as that given to a crop of Corn. The ground is cultivated several times and kept loose until the surface roots appear, when a mulch of manure is given. Chrysanthemums are very impatient of surplus moisture at the roots (no plants more so), and the object being to produce stocky plants with short joints, they are seldom watered at the roots during a normal season unless they show signs of being dry.

Discretion must be used in reading these signs, as some plants with drooping foliage, like Soleil Levant, always appear to lack moisture. Water is usually applied overhead to keep the foliage fresh and to induce breaks. My plants are never "stopped," as they almost invariably produce more stems than are needed, and, besides this, I prefer to have them throw their blooms high. If plants are frequently stopped, one cannot pluck stems two or three feet long, which add so much grace to the cut flowers. In August the plants are gone over and tied up thoroughly, in anticipation of high winds, and to avoid restaking the stakes are cobwebbed together with strong twine. When ready to show, rails are run between the double rows and the plants tied closely and securely back. The aisles seem narrow, yet several thousand people passed between them last season without injuring a plant. Disbudding is the nice art of Chrysanthemum culture, and is a matter of experience and judgment. In a general way, I prefer to remove all but one bud, preferably the crown bud, from each stem. However thoroughly one disbuds, he will wish before the end of the season that he had removed a few more, for only in this way can fine, characteristic flowers be had. Of course there are exceptions. One reads in the papers frequently of some one who prefers the flowers in all their natural luxuriance, but, in actual practice, I find that visitors universally appreciate the best productions. Six, seven and eight inch flowers are no rarities now, and many of these are as refined as the smaller ones, if not overdone in the culture.

John N. Gerard.

Ferns for Cutting.

IN estimating the relative value of various species and varieties of Ferns for use in a cut state, some special qualities are to be considered, the more important ones being beauty, durability and rapidity of growth. It is also desirable that they should be easy to propagate, so that the stock can be quickly renewed when the plants become weakened by frequent use of the knife. In beauty, few Ferns, if any, excel the *Adiantums*, taken as a group, and several of the varieties, notably *A. Wiegandi*, last a long time when cut.

But though this variety makes a very pretty plant, it has not the elegance and grace of *A. cuneatum*, *A. cuneatum grandiceps* or *A. gracillimum*, the latter having a most beautiful effect when used with skill in arrangements of white or

pink flowers, its delicate pinnae appearing like a green lace-work among the flowers.

In addition to the above-mentioned species and varieties, *A. decorum* may be used as a substitute for *A. cuneatum*, it more convenient to do so, its strong fronds of similar general outline being tough enough to stand considerable exposure. In choice arrangements, those of Orchid flowers, for instance, *A. Farleyense* is almost indispensable. The varieties named are probably the most useful of this family in general cultivation, and all are easily propagated from spores, with the exception of *A. Farleyense*, which is readily increased by division.

The next in order for general usefulness are several species of *Pteris*, most of which are of the easiest cultivation, while for lasting qualities they are decidedly some of the best. *Pteris Cretica* and its varieties *magnifica* and *albo-lineata* keep in good condition for several days, in water, while *P. serrulata* and several garden forms of this well-known sort are very

cutting, but in many establishments the plants are not large or numerous enough to warrant a free use of the knife; but where a few fronds of this handsome species can be spared for decorating, it will be noted that fronds of *G. dichotoma*, when placed in water, stand the test of a warm room for as long a period as those of any Fern so used, and from their peculiarly formed growth are sure to attract attention and commendation.

Philadelphia, November 23d.

H.

Chrysanthemums.—It often happens after Chrysanthemums have done flowering that they are stowed away either under green-house benches, where there is but little light, or in cellars where there is less, or are left out in the weather to struggle as best they can with the elements. Good Chrysanthemums cannot be had next year from stock subjected to such treatment. Growers who aim at fine plants and fine flowers are now giving their stock-plants the best attention; the weaker kinds are placed in a cold green-house or frame, close

A Garden of Chrysanthemums.—See opposite page.

pretty, and capable of standing a great deal of rough usage; while if large fronds are needed for any special purpose, *P. argyrea* and *P. tremula* are among the best varieties to furnish them, though they will not stand quite so long as those of *P. Cretica* and *P. serrulata*, and they are also rather more brittle.

After the *Pteris* may be placed *Onychium Japonicum* and *Davallia tenuifolia striata*, both of which are excellent Ferns for either florists or amateurs, though they do not recover from a severe cutting in so short a time as plants of the genus first named, and in the case of the *Davallia* it is also somewhat more difficult to raise a quantity from spores. Another Fern frequently seen and very useful at times is *Microlepis hirta cristata*, its long and graceful fronds being seen to advantage in large baskets and similar arrangements. I lately saw a pleasing effect produced by the use of a few fronds of *Microlepis* in a basket of Chrysanthemums, this being one of the few Ferns which may safely be used among these flowers without seeming out of place. Some of the *Nephrolepis* are also very good for our purpose, *N. exaltata* and *N. davallioides furcans* being among the most suitable on account of the strong texture of their fronds and their rapid and persistent growth. Much might be said of the good qualities of the *Gleichenias* for

to the light, and they are never allowed to want for water; the stronger kinds have also good positions in airy frames or green-houses. All are kept free from insects and mildew. Cuttings will be made of the slower growing kinds as soon as they have obtained sufficient vigor. The best Chrysanthemums are only obtained from cuttings taken from plants that are perfectly strong and healthy.

Pearl River, N. Y.

John Thorpe.

Haplocarpa Leichtlini.—I have grown this little south African composite plant for the past three years, and am well pleased with it as a border flower, but it is of no use for cutting, as its blossoms do not stay open after they are cut and removed to an ordinarily lighted room. The plants are stemless, and form rosettes of Dandelion-shaped leaves, seven to nine inches long, glossy above and thickly covered with white, closely-pressed silky down beneath. The flowers are two to three inches across, golden yellow backed with purplish-brown, showy and borne singly on scapes ten to thirteen inches high. They shut up at night and in dull weather. The plant is not hardy, and ten degrees of frost will kill it outright. Although a perennial, it seeds freely and the seeds germinate readily, and if sown in spring they give blooming plants by midsummer, and these plants continue to bloom uninterruptedly till cut down by November frosts.

Glen Cove, L. I.

William Falconer.

Tea Rose, Madame Hoste.—This is a Rose of great promise, and judging from our own experience, it will take rank with the most valuable of its class. It possesses a good constitution, is strong, but not coarse, in growth, and has abundant dark green foliage. The bud is larger than that of *Perle des Jardins*, and of rounder, yet finely pointed, form, while its beautiful lemon tint is most pleasing. Not the least of its charm is its beauty when fully open. Within the past few days flowers have developed here which rival the largest and most

perfect Maréchal Neils. There is little doubt that it will prove a valuable bedding variety; and as to its suitability for forcing under glass there can no longer be a question. M. Guillo, to whom we are indebted for this magnificent variety, has once more placed the lovers of fine Roses under grateful obligation to his house.

E. G. Hill.

The Forest.

The Forest Vegetation of North Mexico.—X.

IF we continue, over the plains and amongst the foothills bordering them, our examination of the frutescent species of Chihuahua, we shall find sparsely scattered through the chaparral several shrubs of interest in one regard or another—*Cassia Wislizeni*, Gray, in small clumps about six feet high, for its abundant yellow bloom shown in April, and again after the midsummer rains have refreshed the country; *Anisacanthus insignis*, Gray, a slender bush three to six feet high, for its showy light purple flowers, which appear on the leafless branches in March; *Zizyphus lycioides*, Gray, growing in clusters six or eight feet high, for its burden of blue-black berries, long persisting; *Acacia constricta*, Benth., here merely a shrub with tall, slender stems, for the delightful fragrance of its flowers, growing in little yellow heads strung on the virgate branches, which throughout several months of the year betray to all passing near the presence of this shrub; *Lippia lycioides*, Steud., a tall and tender shrub, often supported by other species, for a similarly sweet and long continued perfume; *Dicraurus leptocladus*, Hook. f., a low, soft bush, for its feathery panicles of fruit; *Ephedra trifurca*, Torr., two to ten feet high in clumps, for its rush-like, leafless branches; and *Ephedra pedunculata*, Engelm., a vine-like plant climbing amongst shrubbery, for its numerous scarlet berry-like fruits.

On the extensive sandy plain, in some parts shifting sand-hills, lying south of Paso del Norte, *Bigelovia pulchella*, Gray, *Artemisia filifolia*, Torr., and *Polomintha incana*, Gray, are scattered as small shrubs amongst clumps of Mesquite. In arroyos of the plains *Brickellia laciniata*, Gray, and *Hymenoclea monogyra*, Gray, are woody-stemmed plants a few feet in height. A wild Grape, *Vitis Arizonica*, Engelm., bearing clusters of a few small berries, grows on river banks. Two species of Baccharis, *B. angustifolia*, Michx., and *B. glutinosa*, Pers., border streams or cover their higher gravel. The Osier-like stems of these two common plants, harvested before the resin-covered leaves fall, and bound into bundles, serve as fuel for burning tiles, lime, etc. *Senecio salignus*, DC., and *Varilla Mexicana*, Gray, are woody composites of the lower valleys, conspicuous in March for profuse yellow flowers.

The low shrubs which occupy the mesas of thin soil on a cemented foundation, previously described, are chiefly *Larrea Mexicana*, Moric., and *Flourensia cornua*, DC., the leaves of both covered with resin as a protection against drought, and the following, whose leaves have a velvety covering, serving the same end—*Parthenium incanum*, HBK., *Lippia Wrightii*, Gray, *Buddleia marrubifolia*, Benth., with round heads of orange-colored flowers, and *Leucophyllum minus*, Gray, whose deep purple flowers contrast well with its silvery leaves. Quite at home amongst these, and overtopping them, we notice *Rhus microphylla*, Engelm., six or eight feet high, and attractive with its scarlet fruits, and a depauperate state of *Acacia constricta*, Benth.

Approaching finally the foot-hills by the arroyos, strewn with gravel and boulders, through which their torrents rush down to the plain, channels left dry throughout most of the year, however, we pass a straggling growth of shrubs, the acquaintance of many of which we have already made upon the plain. From the arroyos we follow into the gulches and cañons others, however, which better love the hills,—*Morus microphylla*, Buckl., ten to fifteen feet high, of interest as yielding fruit, though small and barely edible, perhaps the best wild fruit to be found; *Ptelia angustifolia*, Benth., five to twelve feet, of slender, irregular habit;

Garrya Wrightii, Torr., six feet high, a leafy evergreen; *Berberis trifoliolata*, Moric., a Berberry with glaucous, pungent leaves and the usual scarlet berries; *Ungradija speciosa*, Endl., loaded in earliest spring with pink flowers; *Rhus virens*, Lindh., approaching arborescent proportions, with shining evergreen leaves, pink flowers and scarlet fruits; *Loucera albiflora*, T. & G., a white-flowered Honey-suckle; *Cotoneaster denticulata*, HBK., six to eight feet high, and loaded with rosy-white fruits of the size of Huckleberries; *Forestiera phillyreoides*, Torr., six to ten feet high; *Mimosa prolifica*, Watson, four or five feet; *Rhamnus Californica*, Esch., fifteen feet; and *Colubrina Texensis*, Gray, ten to fifteen feet high.

Without the cañons we find preferring more open situations, on the lesser hills, *Eysenhardtia spinosa*, Engelm., one to two feet; *Tecoma stans*, Juss., three to six feet, brilliant throughout the growing season with shining yellow flowers; *Mimosa dysocarpa*, Benth., and *M. Pringlei*, Watson, both pretty, with a profusion of purplish flower clusters; *Mortonia scabrella*, Gray, two or three feet; *Adolphia infesta*, Meisn., spiny and almost leafless, in broad clumps; but a foot or two high; that strange plant, *Fouquieria splendens*, Engelm., with virgate stems ten to fifteen feet high, several spreading from a common crown and terminated by a cluster of flaming red flowers; and *Vanuelinia corymbosa*, Corr., a beautiful shrub of a few feet in height with compact, evergreen foliage and corymbs of white flowers; on the upper slopes and summits—*Ceanothus Greggii*, Gray; *Covania Mexicana*, Don, three to six feet high; *Cercocarpus parvifolius*, Nutt., ten feet; and *Fendlera rupicola*, Engelm. and Gray.

In cañons of mountains about the Laguna country were found, besides many of the above,—*Acacia crassifolia*, Gray, *A. Berlandieri*, Benth., and *A. anisophylla*, Watson, *n. sp.*, *Bauhinia uniflora*, Watson, *n. sp.*, showy, with purple flowers, and *Randia Pringlei*, Gray, with white fragrant flowers, all about fifteen feet high, and doubtfully to be included among shrubs. *Hoffmanseggia fruticosa*, Watson, *n. sp.*, and *Machaonia Pringlei*, Gray, *n. sp.*, a lovely evergreen with white flowers, were but three to five feet high.

Correspondence.

An Appeal for Pretty Plants.

To the Editor of GARDEN AND FOREST:

Sir.—I am a vulgarian. I like pretty plants. I also like to own them. I like to see them growing on my little grounds. I like them just as much if they come from far away as if they were first found near at hand; and if they are very unlike what all my neighbors have, I love my pretty plants the better for that. I enjoy gathering around me handsome shrubs and trees which I couldn't otherwise see short of a horticultural park or a big arboretum. To my low taste it isn't the end of all perfection in planting to secure "repose," or general sleepiness, or so refined a commonplace that nobody will notice whether anything is growing near my house. I rebel against Mr. Olmsted and you, and only a revolt will ease my mind and temper when you go to laying down those austere rules of landscape-gardening. What! May some high artist come along, and order out of the ground my pluming Pampas Grass and striped Eulalias, my delicious Japanese Maples and the Paulownia which I cut down every year that it may yield me leaves more than two feet across, my Hydrangea Grandifloras, all in a bouncing bed, my dainty blue Spruce and delicate Deodar Cedar, my Retinisporas, too various to describe in a letter of protest, and my Irish Yew, black as the Sun-ray Pine is yellow? Shall he make me believe that all the people who look over my fence as they go by and who say this lawn is the neatest thing in the neighborhood, lack good taste for admiring a plain man's collection of all the fine things he could find a nice place for and make grow out-of-doors? Why may I not think a dark Austrian and a light Scotch Pine set each other off as well in Pennsylvania as if they were planted t'other side of the sea? Why are not that rich Nordmann Fir and that bland Nobilis as charming side by side as if one were thriving unseen in the Crimea and the other were hidden away in the Sierras?

It's of no use to go on. I am too dull to understand why pretty things cease to be pretty when they become strikingly pretty. I think you have hit it with regard to the glaring calico beds of Coleus. Some sense ought to be shown in putting colors together; but green is not the only color in trees worth looking at by vulgar eyes. If you will make a pilgrimage far out Chestnut Street, in Philadelphia, as I do two or three times a year, just to see a purple Beech, purple as any bedding plant, big as a house, and round as a Cabbage, with a cut-leaved, Weeping Birch for one neighbor and a Cedar of Lebanon hard by in a corner, I am sure you would enjoy these rare beauties which, as a critic, you condemn, because they are not commonplace and easy to overlook. Make your high-class parks as prim and plain as you will, but pardon common folk for putting pretty things where they can see them grow and where they can be proud of them.

Simple Simon.

Chester, Pa.

[Our correspondent has entirely failed to comprehend the scope and aims of this journal if he imagines that we do not cordially share his admiration for beautiful plants. All those which he mentions are handsome and appropriate objects in a garden or upon a lawn adjacent to a dwelling-house; and if he has succeeded in grouping them so as to bring out all their beauties with the same taste and knowledge which he has displayed in their selection, his neighbors have good reason for stopping to look at his garden. But if he has succeeded in grouping them in this manner he may feel very sure that—apparently without his knowledge and perhaps even against his will—he has secured an effect of “repose,” of harmony, of variety in unity, although not necessarily of “sleepiness” or commonplaceness. The mistake he makes, and it is one of very general occurrence, is that he confounds the treatment of a yard or small garden in a thickly settled, or comparatively thickly settled, region, with landscape-gardening—that is, with the development of surfaces, the treatment of water and the arrangement of plants in such a way as to produce living pictures on a large scale, which are successful as they imitate or surpass natural effects. When a small garden or a small lawn forms part of a wider and more extended picture it demands a treatment which shall be in harmony with its surroundings, or with the views, natural or artificial, which can be seen from it. But, as a general rule, a small garden must be treated as a unit and independently of its surroundings; and in such a garden plants which would appear inappropriate and out of place in a large landscape picture, are not only appropriate, but the most desirable plants to use. A garden exists largely for the sake of its plants; with a park or landscape the reverse is the case—the plants exist for the sake of the picture as a whole. But even in the smallest garden an over-accumulation of trees and shrubs and flowers, a confusion of incongruous forms and colors, a fussy, heterogeneous, disorderly arrangement can never be satisfactory, for under such circumstances the plants themselves cannot appear to the best advantage. If our correspondent's garden is as pleasing in effect as we gather from his words, its arrangement is orderly, no matter how unsymmetrical and informal it may be; forms and colors are well contrasted; each plant helps instead of hurting the beauty of its neighbors, and therefore the effect is a reposeful one. That it includes many striking elements does not alter this fact—some of the finest, most complete and reposeful works of art that the world can show contain very striking elements. The whole question is not one of elements, but of their use, and all we have tried to impress upon our readers is that the more striking the material, the more difficult it is to use it really well, and that material which is not striking is the safest to employ. Given a due degree of knowledge and taste there is no reason why all the plants mentioned by our correspondent, and many more besides, cannot be planted in such a manner upon a small piece of ground as to produce an attractive and interesting garden. The development of these plants will afford new pleasures or new disappointments every year; and the man who plants and maintains such a garden should be considered a benefactor to the community in which he lives. It is a

collection of plants, however, which he creates, and not a landscape picture. Each is valuable and interesting, and each is capable of affording real and lasting pleasure; but they must not be confounded, and the man who can successfully plant, and so make the most of his door-yard, must not think that he is a landscape-gardener. — Ed.]

To the Editor of GARDEN AND FOREST :

Sir.—In striking contrast with the vicinity of Lebanon, Pennsylvania, where the portable saw-mill, at so much per acre, has devastated the country of its most valuable trees, I observed during a recent visit to Dauphin County, Pennsylvania, that most of the mountain land throughout an extensive region in that part of the state is still covered with forests. As it is too rough and steep for cultivation, it should, of course, be kept permanently wooded. The soil is good, and it originally produced a heavy growth of Chestnut Oak, White and Black Oak, Hickory, Walnut, Ash and Chestnut trees. Most of this was cut off thirty or thirty-five years ago, but where the land is not burned over or pastured the trees are rapidly re-produced. There are many springs and small streams in this woodland region, and these are of great value, not alone to the few farmers living in the small valleys, but their steady flow is also of importance to the dwellers along the rivers which carry these waters to the sea. Some plan for taking care of these woods ought to form part of the education of the people of this part of the country. They are hard-working, sensible men and women, with a great deal of character, most of them poor. How can they be reached and taught what they need to know and think of and practice in regard to the forest interests of their region and the best ways of managing their own woodlands?

Philadelphia.

M. B. C.

To the Editor of GARDEN AND FOREST :

Sir.—Owing to unusual rains in August and September, and the continued warm weather, much of the vegetation here has put on the appearance of spring. The Elms on the east and south sides of the hills are in full bloom. The Japan Quince and Forsythia are full of scarlet and yellow blossoms. The Daffodils, single Hyacinths, Jonquils and Flower-de-Luces are several inches above ground. The perennial Sweet Pea has put out fresh sprays; their delicate, beautiful green makes a lovely addition to cut-flowers for the table. I have just gathered from my garden, besides late Chrysanthemums, blue (sweet) Violets; Louis Philippe, Bougère, Lamarque, Duchesse Brabant, the fragrant, old-fashioned “Blush-cluster” and pink daily Roses; Dwarf Iris and Woodbine, of which we have a variety that is nearly a perpetual bloomer. I have gathered blossoms from it as late as Christmas Day and as early as February 15th. The trumpet-shaped flowers are scarlet on the outside and orange on the inside.

College Grove, Tennessee, November 29th.

Alice W. Rucker.

Recent Publications.

The Origin of Floral Structures through Insect and other Agencies. By the Rev. George Henslow, Professor of Botany, Queen's College. 349 pages, and numerous illustrations. D. Appleton & Co., New York, 1888.

The author has felt impressed by what he regards as the inadequacy of the theory of Natural Selection to account for the diversities of form and structure in the vegetable world.

As generally understood, the Darwinian theory recognizes (1) the fact that organisms vary from generation to generation, the descendant differing more or less from its progenitors in some way or other; (2) that more descendants are produced than can, under existing circumstances, possibly come to maturity, and (3) that of the variant forms, those will, of course, stand the best chance of coming to maturity which are best fitted to meet their surroundings. In other phrase, Nature selects the fittest, and these survive. But the question naturally arises, may not the surroundings have played an important part not merely in selecting advantageous variations, but in originating all variations? This question has presented itself to the minds of many investigators in the Old World, and it has been thoughtfully treated by Cope, Hyatt and Ryder in this country. This is the inquiry which Professor Henslow places before the reader in the work under consideration, and he employs in some cases the terms which had been previously used by the American students above mentioned, whose works were doubtless unknown to him.

At the outset we will say that the book appears to be a useful contribution to the subject. It is attractive and readable throughout, but to us it has been unsatisfactory, or, rather, unsatisfying. The lack does not arise so much from the method of reasoning or of statement of observed or cited facts, as from the author's use of terms. This may be illustrated by a reference to the beginning of the book. After assuming the ideal type of floral structure, he proceeds as follows: "We may at once consider the 'Principles of Variation,' as I propose to call them, in accordance with which the different members of flowers can be altered." "There are five principles which require special consideration. They are usually designated by the terms number, arrangement, cohesion, adhesion and form." "The above five principles constitute the most important, *in accordance with which Nature has brought about* the infinite diversity which exists in the floral world. There are minor *distinctions* hereafter to be considered, such as colors, scents, etc.; but they are of less importance in investigating the causes at work which have evolved specific and generic differences amongst flowering plants." This sentence, in which we have placed italics, appears to indicate that the author makes no clear discrimination between a principle and a distinction, since the first is said simply to be more important than the latter. In other words, he employs the term principle to express distinctive character or distinction, and yet having appropriated it for this purpose, as he perhaps had a perfect right to do, makes it do double duty as a law or mode of action "in accordance with which Nature has brought about the infinite diversity which exists in the vegetable world." The author has probably not felt that any ambiguity can arise from such use of terms, but the casual reader and the careful student alike, who take up the book for the first time, will be liable to entertain a distrust which is not wholly warranted. The book ought to do good service in stimulating observation and in exciting intelligent inquiry even among those who are not botanists.

A Catalogue of Canadian Plants. Part IV.—Endogens. By John Macoun. Montreal, 1888.

Another part of this work, being Part I. of the second volume, covering the endogenous plants of British North America, has been issued by the Geological and Natural History Survey of Canada. It is to be followed by two additional parts to be devoted to the Ferns, with the Mosses and Liverworts, and to Lichens, Fungi and Seaweeds. Considerable additions to the knowledge of British American plants have been acquired during the past two years, through collections made on the shores and islands of James' Bay, by Mr. James M. Macoun, a son of the author of the catalogue, who himself spent several months in studying the botany of Vancouver's Island, and by Mr. G. M. Dawson, who devoted the summer of 1887 to exploring that portion of the North-west Territories which is adjacent to Alaska, a journey whose most interesting botanical features have already been described by Mr. Dawson in the columns of this journal. The results of this journey, so far as they relate to the Endogens, are contained in the present volume. Professor Macoun estimates that the entire work, when completed, will contain, including 2,500 cryptogamous plants, the enumeration of about 5,500 species of plants, native and introduced, found growing without cultivation, within the limits of the Canadian Dominion.

Periodical Literature.

The November number of the *Bulletin of Miscellaneous Information*, issued from the Royal Gardens, Kew, contains the usual amount of valuable information relating to economic plants and plant products, which makes this periodical invaluable to all persons interested in economic botany and in tropical agriculture.

The principal articles are upon the Lagos Rubber (*Ficus Vogelii*), from which the following quotations are of general interest:

"The investigation of plants likely to yield the caoutchouc of commerce is being carried out in west tropical Africa by numerous correspondents of Kew. Possibly in no other part of the world is there such a wide field for investigation of this kind, and in recent years a considerable trade in India-rubber has arisen through the exertions of officials and traders who have given attention to this subject. At present the chief rubber-yielding plants on the west coast appear to belong to a species of *Landolphia*. These are climbing shrubs with stems four to six inches in diameter near the ground, but dividing above into numerous branches, which support themselves on

the neighboring trees. The rubber of the Gold Coast, known in commerce as Accra rubber, is the product of *Landolphia owariensis*, Beauv. This is probably the best rubber plant in west Africa. The rubber is obtained by cutting off portions of the bark in strips varying in length from three to ten inches. The cuts are made sufficiently deep to reach the latex canals, and soon the crude juice starts out in drops and gathers on the newly-cut surface. The rubber of the *Landolphia* coagulates on exposure to the air, and requires no other preparation other than rolling it up into balls. 'A quantity of the milk is first dabbed on the fore-arm of the operator, and being peeled off, forms a nucleus of the ball. This nucleus is applied to one after another of the fresh cuts, and being turned with a rotary motion, the coagulated milk is wound off like silk from a cocoon. The coagulation takes place so rapidly on exposure to the air, that not only is every particle cleanly removed from the cuttings, but also a large quantity of the semi-coagulated milk is drawn out from beneath the uncut bark, and during the process a break in the thread rarely occurs.'

"Another method of collecting west Africa rubber is described as follows: The blacks wipe off the milk with their fingers and smear it on their arms, shoulders and breasts, until a thick covering of rubber is formed. This is peeled off their bodies and cut into small squares, which are then said to be boiled in water. In European markets such rubber appears in more or less agglutinated masses of small cubes.

"The investigations undertaken by Mr. Millson in west Africa are described in the following notes:

"In nearly all the native villages in the western district of the Colony of Lagos, and, I believe, throughout the colony and the interior, are to be found large spreading trees, which have been planted for shade in the market places, streets and compounds. These trees are of the Fig family, and are called by the natives Abba. I have measured a tree of this species of the age of thirteen years, and found its girth, at three feet from the ground, to be six feet four inches, and its height to the branches twelve feet, while its total height could not be less than fifty or sixty feet, and its foliage area a quarter of an acre. A tree of this size ought to give large quantities of milk if tapped at the right time of the year. Although it was in fruit when I tapped it, and the season being very dry, was in every respect unsuitable, yet the milk exuded in large drops, and flowed for a considerable distance down the trunk. Three quarts of milk were extracted from this tree without injuring it in any way, and I have little doubt that at any time between the months of July and February from four to five gallons could have been obtained with but little trouble. The trees, however, should only be tapped on alternate years, so as to leave time for a fresh growth of bark to replace that which has been removed. It is difficult to form an accurate estimate of the percentage of dry rubber that would be yielded by a gallon of milk, but I have reason to believe from previous experiments on Central American rubber trees (*Castilloa elastica*) of similar richness of milk, that each gallon should give about three pounds of India rubber. The value of the rubber produced depends largely upon the care with which it is prepared, and I have reason to believe that the milk of this species, at least, of the "Abba" tree, can be made to give an excellent sample.

"Should the above facts be established, it becomes evident that plantations of the "Abba" tree would be a highly profitable investment. It is planted by the simple method of cutting off a branch and pushing it into the ground, and on account of the facility and rapidity with which it is raised, the natives used it largely for fence-posts. From the trees already in full growth in the bush and towns a considerable export trade could be readily established, and careful planting would develop this trade to almost an unlimited extent."

In the article upon Liberian Coffee at the Straits Settlements it appears that "as a commercial article Liberian Coffee has not hitherto proved so valuable as was at one time supposed, and the cultivation, though widely distributed, has not become general in any part of the world. There are, doubtless, good reasons for this. It has been found, for instance, that the "cherries" of Liberian Coffee do not become soft and pulpy when ripe, but remain hard and fibrous. Hence it has been found difficult to husk the beans, as the machinery found suitable for preparing Arabian Coffee is not applicable to the Liberian Coffee. Again, the "parchment" skin is tough and woody in the latter, and the labor and percentage of waste entailed in "cleaning" is increased, while the actual market value is lessened. Probably, also, in the cultivation of Liberian Coffee the localities selected for plantations have, in many cases, been subject to long droughts, whereas the species evidently prefers a warm, moist climate, with abundant rains

well distributed through the year. Should the present high price of Coffee be maintained it is not unlikely that the cultivation of Liberian Coffee will prove sufficiently remunerative to warrant further attention being paid to it.

Tea cake is prepared from a species of *Camellia* (*Camellia Sasanqua*), which "is extensively grown in south China for the production of seeds, which produce a valuable oil, known as *Tea Oil*. The preparation is very simple. The seeds are collected in October or November, dried and taken to the mill, where they are crushed in a circular mortar or trough by a pestle driven through it by water power. The seeds after being crushed are steamed, and then the mass is placed in a powerful press, which expresses the oil. The refuse, after the extraction of the oil, is the article known as *Ch'à tsia ping*. It is produced in cakes weighing, when dry, about three ounces and three and a half pounds respectively. The quality of the two kinds of cake is the same. I am not aware that anything besides the seeds of *Camellia Sasanqua* enters into the composition of these cakes. *Ch'à tsia ping* is used by the Chinese as a hair wash and as soap for cleansing both the person and the clothes. It is also used for eradicating earth-worms from grass lawns. For this purpose the cake is crushed and boiled. The decoction is then diluted and poured on the grass, when the worms come to the surface of the ground. As a rule, the small worms die, but the larger ones after a time recover. After being picked up from the grass the worms are often given to fowls and ducks, which devour them readily, and apparently thrive on them, experiencing no inconvenience from the effects of the *Ch'à tsia ping* with which the worms were killed."

There are articles on the Demerara Pink Root (*Spigelia anthelmia*), a plant possessing powerful drastic properties, which renders it exceedingly dangerous for animals to graze upon the ground where this plant grows. On the food grains of India, with an analysis of the fruit of *Croix gigantea*. On the Yoruba Indigo (*Lonchocarpus cyanescens*). On the Trinidad Ipecacuanha (*Cephaelis tomentosa*), from which it appears that "the demand for the official Ipecacuanha is steadily increasing, while the supply of the drug is either stationary or gradually becoming scarcer. Inquiry is, therefore, naturally directed to plants that may possess similar properties, in the hope that they may serve to supplement or replace the drug hitherto exclusively in use."

There are also articles on the Treatment of Vines in France; on Huskless Barley; and a report upon a series of trials of the methods of preparing Ramie fibre, recently undertaken in Paris under the auspices of the French Government.

We cannot find space for more extended quotations for this issue of the *Bulletin*, which is certainly one of the most useful of the various publications prepared in the Royal Gardens.

The last number of *Hooker's Icones*, which appeared in October, completes the eighth volume of the third series, or Volume XVIII. of the entire work.

Among the plants figured in this issue, which are interesting from other points of view than that of pure science, is the curious *Musa proboscidea*, *t. 1777*; a Banana from the hills of Ukami, in tropical Africa, about 100 miles inland to the west of the Island of Zanzibar, the long axis of the inflorescence hanging down, as shown from a photograph, to about one-third the height of the stems above the ground. *Parnassia Faberi*, *t. 1778*, is a minute, but very attractive, species, from Mount Omei, in central China, where it was discovered by the Reverend E. Faber at an elevation of 4,500 feet. *Ilex macrocarpa*, *t. 1787*, is a stout shrub or tree which sometimes attains a height of fifty feet, with large, deciduous leaves and black fruits. It is one of Dr. Henry's interesting discoveries in the Ichang gorge of the Nanto'o Mountains, and was sent also from the Kwangtang Province by C. Ford. It may be expected to be valuable in cultivation. And this is true, also, of *Lindera fragrans*, *t. 1788*, another discovery of Dr. Henry's, who remarks, in regard to this elegant plant, that "the leaves are pounded in milk in the glens, and the powder mixed with that got from the roots of Biota, . . . in a similar way; it is used for making Joss-sticks—sticks of incense used in religious worship." The flowers are fragrant.

Primula Faberi, *t. 1789*, is an addition to the series of Chinese Primroses which are among the most important of the Abbé Delavay's recent discoveries in south-eastern China. It is distinguished by the conspicuous involucre, in which the calyxes of the stout-pediceled flowers are almost hidden. *Lonchocarpus cyanescens*, *t. 1791*, a native of the Yoruba country, a region north of Abbeokuta, is the plant which produces the so-called "Yomba Indigo," which is prepared by

pounding the young leaves to a black, pasty condition, and then made up into balls for market. The dye is a fine deep blue in color and very permanent.

Cadrania triloba, *t. 1792*, is a member of the family to which the Mulberry belongs. It is the "Silkworm Tree," and is known in China, where it is quite widely distributed, as the "Tsa" tree. Dr. Henry reports "that it is common about Ichang, where it is considered to be as good for silkworms as the Mulberry, but it is not used so long as Mulberry leaves can be got, because the tree is thorny and it is troublesome to pick off the leaves. It is hence given chiefly to adult silkworms, and, as Mulberry leaves soon become finished, it is much used." The tree attains a height of twenty feet. The leafy shoots, more especially those from near the base of the plant, are often armed with strong, stout, axillary spines.

Achras Bahamensis, *t. 1795*, a native of the Bahamas, and No. 3837 of Baron Eggers' recent Bahama collection. Mr. Baker finds it "very distinct from the well-known *Achras Sapota*, not only in the leaf, but also in the structure of the flower, having the segments of the corolla twelve in number instead of six, so that unless it be made a new genus, the character of *Achras* will have to be materially enlarged." We venture to suggest that this plant is the *Mimusops Sieberi* of A. De Candolle, a common tree of semi-tropical Florida and of the West Indies—a view which is supported by the plate itself, which very well shows the six-parted corolla, with the two appendages at the base of each division, and the short, triangular and nearly entire staminodia alternate with the lobes of the corolla, which characterize *Mimusop*. The figure in Catesby's "Natural History of Carolina, Florida and the Bahama Islands," to which Mr. Baker calls attention, displays the fruit accurately enough, and there is another figure, although a less satisfactory one, in Nuttall's *Sylva* (iii., 28, *t. 90*), in which the fruit of some other plant seems to have been substituted for that of the *Mimusops*, which is depressed-globular, about one inch in diameter, dark russet brown when ripe, and barely edible.

Sir Joseph Hooker figures and describes, in this part of the *Icones*, a number of Indian Orchids, principally belonging to the genus *Oberonia*, a fact which leads us to hope that his examination of Indian plants for the "Botany of India" is nearing completion, and that the final parts of this work, one of the most important of the great floras to which the studies of many years of his life have been devoted and which no hand but his can so well take up, may soon be expected.

Notes.

The Eulogy of Richard Jefferies, which was reviewed in this journal last week, is published in this country by Messrs. Longmans, Green & Co.

The thirty-first annual meeting of the Missouri State Horticultural Society, held on December 5th at Nevada, was exceptionally interesting. More than one thousand plates of fruit were on exhibition, beside an abundance of choice vegetables and flowers.

In the *Popular Science Monthly* for December will be found a translation in full of the Marquis de Saporta's interesting article on "The Origin of Forest Groupings," to which we called attention some months ago, when it was published in the *Revue des Deux Mondes*.

Mr. Weiger, of the Botanic Gardens in Adelaide, writes to *The Garden* (London) describing one of the finest existing specimens of "Fortune's Rose." It stands near the fountain in the garden, was planted twenty-six years ago, and has received no special care, although copiously watered in the dry season. It is a veritable tree, being about twelve feet in height and the same in diameter, while at a foot above the ground, where it breaks into several branches, the stem measures a yard in circumference.

Dr. Hildebrand, who recently published in Wildeman's *Annalen der Physik und Chemie* the results of his investigations into the action of moisture upon different kinds of wood, says that more care than is now taken should be exercised in choosing wood for measuring-rules. Mahogany and oak are frequently used for this purpose, but are entirely unfit for it; maple, fir, beech and linden woods being far preferable. With no wood, however, can absolute stability, and therefore accuracy, be depended upon, even though polish, oil or lacquer be applied to its surface. Air, saturated with steam, will penetrate all but the very best lacquer, and even ivory does not entirely resist its action.

The Pecan nuts now sold in some retail shops are specially prepared for the market. Large nuts of uniform size are selected and placed in an iron cylinder, which is made to revolve by machinery. The nuts are thus made perfectly smooth by attrition, a uniform dark brown color being given to them by putting into the revolving cylinder some coloring substance, the composition of which is still a secret of the trade.

A remarkable Horse-Chestnut to be growing so far north stands at Skene House in Scotland, one of the seats of the Earl of Fife. It is fifty-eight feet in height and its trunk girths thirteen feet above the swell of the roots, while the branches, in spite of the fact that they were cut back when the tree was younger, droop quite to the ground, inclosing an open area ninety feet in greatest diameter. It stands about 350 feet above the sea level in a soil of deep loam resting on gravelly clay.

It is well known that very few Ferns of any commercial value have been left in Epping Forest or in the other woods around London. According to *The Garden*, however, no mercy is shown to these plants, even in remote country districts. A few years ago Hart's-tongue Ferns were growing in abundance on the old wall which formed part of the ruined Abbey of Rievaulx, in Yorkshire, and they added as much beauty to that picturesque pile as did the Ivy that had crept in through the windows. Last year every plant was carted away to be sold in the streets of the large towns.

Mr. J. G. Baker describes in a recent issue of the *Gardeners' Chronicle* a new Lily collected by Dr. Henry, to whom it is dedicated, in the mountains of Ichang, in western China. *Lilium Henryi* "in general habit most resembles *L. tigrinum*, but the fully developed leaves most recall those of *L. auratum*, and the narrow perianth segments those of *L. polyphyllum*." The flowers are yellow, the base of the perianth marked with minute red-brown spots, three to three and one-half inches long, and borne in a lax corymb sometimes a foot wide, consisting of from four to eight flowers. This interesting plant, and its geographical neighbor, *Lilium Davidi*, are still to be introduced into gardens.

We are indebted to the Reverend John E. Peters, of Mays Landing, New Jersey, for a seasonable note concerning some fine groups of Holly trees, which are remarkable even in that region famous for the beauty of its forest trees. The trees stand on the border of an "old field," just where the high ground falls away to the swampy border of a creek, so that abundant sunshine, a light soil and a full supply of water give them every needed condition for the best growth. They are not of exceptional size, but they stand in distinct clusters, each of pyramidal shape, and since their lower branches are unusually thick and come quite to the ground, their beauty is distinct and striking. The first group consists of five trees, with a circular base thirty feet in diameter and twenty-five feet high, while the largest tree is only nine inches in diameter. Many trees of greater height and girth are found near by, but none of them approach these groups in beauty. Last year the Hollies bore few berries, but now the bright red fruit fairly illuminates the rich, dark foliage. Complaints are heard from other places that the finest Hollies have been mutilated to supply distant city markets with Christmas green. It is to be hoped that the Mays Landing trees will be saved from such an untimely fate.

Some of the most venerable Oaks in England stand in the grounds of Holwood House, in Kent, a property which now belongs to Earl Derby, but was formerly owned by William Pitt. One of these trees is called the Wilberforce Oak, because Pitt and Wilberforce were seated beneath it when the latter first divulged his intention to bring forward a bill for the abolition of slavery. At five feet from the ground its stem measures eighteen feet three inches in circumference, while its height is forty-two feet, and the spread of its branches fifty-one feet in diameter. The centre of its trunk is hollow, but the shell is still sound and well covered with bark, and the tree bids fair to last for many years, as the greatest care is now bestowed upon it. Not far away from it stands a similar tree, called Pitt's Oak, which at a yard from the ground girths twenty feet one inch. Like its companion, it is not tall, but has enormous branches, diverging at a height of about eight feet, and a hollow stem. A third example girths nearly twenty-two feet. All these Oaks are of the variety called *Quercus robur pedunculata*. A picture of the Wilberforce Oak, with the stone seat erected to commemorate the historic interview, was recently given in *The Garden*, and various other remarkable trees were noted as existing at Holwood—among them two very large Cork Oaks (*Q. suber*), and an Evergreen Oak (*Q. ilex*)—the Ilex tree

familiar to all travelers in the south of Europe—the circumference of which at two feet from the ground is nearly twelve feet.

Earnest attempts are being made in France to further the planting of fruit-trees instead of ordinary shade trees along the public roads. In Germany the practice is very widespread, and has been very remunerative, the sale of the fruit proving more profitable than the sale of the wood of timber trees. In the vicinity of Mulhouse, says the *Revue Horticole*, the Cherry-trees planted by the roadsides have, from their earliest crop, paid the expenses of their purchase and maintenance. Every visitor to Suabia remembers the Plum-trees, and every visitor to Saxony the Cherry-trees, which line all the roads. As there are so many of them the loss from petty thieving is not serious; and, moreover, the crops are sold as soon as the fruit is set to private persons, who take measures for their protection. When they are ripe those at a distance from the towns are gathered for the market, while in the neighborhood of large places a multitude of booths are erected under the trees, and the whole population goes out on pleasant afternoons to eat the fruit on the spot. In Japan it is the blossoming season of the fruit-trees which draws forth the dwellers in cities; but the inhabitants of the Fatherland seem to get a vast amount of pleasure from thus combining the gratification of the inner man with the delighting of the eye as it rests upon the wide, rich summer landscape.

A correspondent of the *Evening Post*, of this city, writes as follows of Chinese graveyards: "The living occupy the city and the level ground, the dead the hills. No corpse is allowed within the walls of a Chinese city, and without, the vast cemeteries cover the hills, with no fence or other limitation about them. The Chinese family which can afford it builds a 'horse-shoe grave,' or bricked vault, on the hillside, with the end built up in horse-shoe shape. Poorer people stick their dead in shallow graves, on which a small tablet of wood or stone is put. . . . In the rich alluvial plains, where no uncultivable hills are available for burying the dead, a graveyard resembles very much a white-ant village in Africa. The graves are sugar-loaf mounds thickly clustered together. While John Chinaman pays great respect to the dead, he takes care that they do not appropriate much ground that is of value to the living. The cemetery of a Chinese village in the rich rice-growing districts covers very little ground in proportion to the number of the graves. . . . In some parts of China one seems to be traveling through cemeteries most of the time. Particularly is this the case in thickly populated districts where the topography is undulating. The ridges where the soil is thin are then the cemeteries, and a rigid spirit of economy has relegated the alignment of the public roads thereto rather than through the fields. In such districts the traveler is in the company of the dead all day long."

In a recent number of the *Bulletin of the Torrey Botanical Club* Mr. W. M. Beauchamp publishes an interesting article on "Onondaga Indian Names of Plants." Omitting the actual names which he prints in numbers, we may quote a few of the appended translations that show a keen sense for the more salient characteristics of trees and flowers and occasionally a touch of true imaginative feeling. The Hemlock Spruce is called "Greens on a Stick;" the Sassafras "Smelling-Stick;" the Balsam Fir "Blisters," from the look of the bark; the Aspen "Noisy Leaf;" the Iron-wood "Everlasting Wood;" the Water Beech "Lean Tree," from the unlikeness of its habit to that of true Beeches, and the Buttonwood "Stockings," probably because of the way in which it sheds its bark. The Mullein is "Flannel" or "Stockings," the Wintergreen "Birch-smelling Plant," the Thorn-bush "Long Eyelashes," from its long thorns, and the Elder, most poetically, "Frost on the Bush," while Peppermint, as expressively, is "That which makes you cold," Poke-weed is "Color weed," and Poison Ivy (from which the Virginia Creeper is not distinguished) "Stick that makes you sore." The Larch is "The Leaves Fall"—which shows that its unlikeness to all other coniferous trees is appreciated; Plantain "It covers the Road," and the Witch Hazel "Spotted Stick." Peach are called "Hairy," Lettuce "Raw Leaf," Chestnut "Prickly Burr" and the Leek "A Queer Onion." The yellow Moccasin-flower is "Whip-poor-will Shoe," the Marsh-Marigold "It opens the Swamps"—surely a pretty name—and Jack-in-the-Pulpit "Indian Cradle," from its likeness to the hooded cradles actually used by the Indians. In many cases the Onondaga names resemble popular English names, as in the case of the Canoe-Birch, the Red Maple, "A Cap," which means a Raspberry, "Three Leaves," which denotes Clover, the Choke-Cherry, the Bloodroot, Catnip, which becomes "Cat-eating Leaf," and the Partridge Berry.
